Address.

SOME REMARKS ON THE PRESENT STATUS OF MEDICAL EDUCATION IN THE UNITED STATES.*

VICTOR C. VAUGHAN, M.D., LL.D.
ANN ARBOR, MICH.

Gentlemen of the Association: In the first place, I desire to say that I greatly appreciate the honor that you conferred on me last year in electing me president of this body. When we compare medical education in our best schools in this country to-day with that of twenty or thirty years ago we feel that we have just cause of self-congratulation. Many of us here to-day went through the course of medicine in two years of six months each, and even then many of the lectures and demonstrations given the first year were repeated in the second. Many of us had but little, and possibly some of us no laboratory instruction other than that of the dissecting room. Now, all the colleges in this association give courses which extend through four years, none of which are less than six months in duration. The majority of these schools have graded courses, thus doing away with all repetition of lectures and demonstrations. The laboratory method has been applied to every branch of medical teaching, and the old theatrical clinic has largely been supplanted by bedside instruction. It is probably true that in no other department of learning has education advanced so rapidly as in medicine. All of this, I say, is a matter on which we as medical teachers may congratulate ourselves, and with some justness claim that we are giving to our students much more and much better instruction than our teachers gave us.

The object of my talk to-day is not to dwell on what has been accomplished in the recent past, but rather to emphasize some of the demands which the present and the future impose on us. We must not satisfy ourselves with the thought that we are doing better work than our predecessors in medical education did, but we must seriously ask ourselves whether or not we are to-day doing all that we should do. If my remarks should appear to some as too critical, please permit me to assure you that I have the welfare of the profession at heart, and that I am not desirous of doing an injustice to anyone, nor, indeed, do I desire to criticise any individual or any school. However, we are not likely to move forward and make improvements unless we become aware of our defects. A certain amount of self-esteem and pride is desirable, but when this article is stored up in quantity sufficient to lead one to believe that he has reached perfection, we can be sure that decay is rapidly advancing. With these preliminary remarks, I am going to say a few plain words with the best of intentions.

Within the past few years much has been said concerning the commercial spirit which has apparently invaded our profession to some extent. Numerous articles have appeared in our journals bearing on this subject, and it has been discussed in nearly every possible phase. The form of commercialism which has attracted most attention is the question of the division of fees between the attending physician and the consultant. This practice has been generally condemned, and it seems to me that the condemnation has been only just. Other forms in which commercialism manifests itself have been the exorbitant fees charged by a few specialists on account of which many people in moderate circumstances have been driven to free dispensaries and free clinics; and, on the other hand, cutting of fees and the doing of professional work, as it were, in job lots, for various organizations. It is needless for me to enumerate all the evidence that might be brought forward in order to show that our profession has not wholly escaped the spirit of commercialism which has so great a hold on the people of this country, and possibly other countries as well, at present.

I will ask the question whether or not our medical schools have been altogether free from commercialism. The individual practitioner places himself outside of the Code of Ethics if he advertises himself; and still if he be a member of a medical faculty he may indirectly do a great deal of self-advertising and still regard his actions as perfectly legitimate. As a rule, the better medical schools do not resort to advertising to any great extent, and as a general proposition it is true that the real value of a school is in inverse ratio to the extent to which it advertises. Dr. John Smith, as a private practitioner of medicine, would under no circumstances go to his brother practitioner's patient and laud his own ability and tell how superior his own attainments are compared with those of the physician in attendance; and yet Dr. John Smith, as secretary or dean of a medical school, does not hesitate to send circulars to students attending other medical schools, telling them of the superior advantages offered by his own institution. The same Dr. John Smith, reputable physician as he is, would hardly send a postal card to a friend in a neighboring town and ask that friend to return the postal card with the names of two sick persons, or to otherwise put him in communication with those sick in order that he might become their physician; and yet Dr. Smith, as secretary or dean of a medical college, sends out such postal cards by the hundreds. I have not known of any premium being offered for the largest number of prospective medical students about whom information could be given, but this is only one step in advance of what is being done, not by the poorest medical schools in the United States, but by some that claim a position among the best. Can it be a matter of surprise that the graduates of these schools enter the medical profession fairly well imbued with the idea that business success is the chief aim of the profession?

---

* Presidential Address before the Association of American Medical Colleges, 1902.

Turning next to the requirements for admission to our medical schools, let me ask if we live up to the requirements which we advertise; and in the second place, are our advertised requirements as high as they should be? On the first of these points I want to say that no one can conduct a fairly large correspondence with prospective medical students without becoming aware of the fact that some of our schools do not live up to their advertised requirements for admission. For this sin on the part of certain schools there is absolutely no justification. There is at present no crying need for more medical men in this country, and certainly not for more poorly educated medical men. As to the second point, I am well aware of the fact that all medical schools can not advance the requirements for admission with the same rapidity. Harvard, with her five-million-dollar endowment, can well afford to cut the number of her students very materially, and this she has had the courage to do, but probably there is no other medical school in the country which could afford to make so radical a change in so short a time. But notwithstanding these facts, it seems to me that it is about time that this Association of American Medical Colleges should be making some advance in the requirements for admission. With the profession overcrowded as it is, with already too many ignorant men in its ranks, the demand for more must be small unless the recruits be selected with the best of care.

There are two ways of teaching medicine. These two methods require different material to start with and their finished products are radically different. Medical knowledge may be defined as embracing all information which can be utilized in the prevention or cure of disease. Physics, chemistry, anatomy, physiology, bacteriology and pathology are some of the sciences, the facts of which are utilized in medicine. Now, one way of teaching medicine consists in taking the isolated facts which can be utilized in the prevention or cure of disease from each of these sciences and teaching these to the student by rote, without ever attempting to give him any real knowledge of the sciences on which medicine is founded. A man may be taught how to fit glasses without ever having any scientific knowledge of the refraction of light or of the construction of lenses. A student can memorize maximum and minimum doses of the alkaloids without ever having any knowledge of the chemical nature of these vegetable products, and without any knowledge of the botanical classification of the plants from which they come. A man may be taught to stain tubercle bacilli, possibly to recognize diphtheria bacteriologically, and even to utilize the Widal test without knowing anything scientifically about bacteriology. A man with knowledge thus acquired and thus limited may pass a fairly creditable examination, but he is not a man who knows anything of real value concerning the sciences on which medicine is founded, and inasmuch as medicine is progressive, such a man is sure to fall behind within a few years at most, and become not an honor, but a disgrace to his profession. He is one who has built on the sands, and the house thus constructed must surely fall. There is too much of this kind of medical teaching in our country to-day. On the other hand, chemistry, biology, physics, anatomy, bacteriology, physiology and pathology should be taught to medical students as independent sciences, and no one should be allowed to enter the medical profession unless he has a fairly comprehensive grasp of each one of these subjects, and his knowledge must not be confined to those isolated facts which at present are utilizable in medicine. Then, when advances come, when changes are made, when new discoveries open up new fields, this man is able to keep abreast of the times. He has the scientific comprehension necessary in order for him to become an intelligent student of progressive medicine.

These statements will undoubtedly be met by the assertion that no one man can hope to make himself a master of any one of these sciences, and much less can he hope to make himself thoroughly familiar with all of them. While this is true, I claim that the medical student should be made perfectly familiar with the fundamental principles of all the sciences that directly contribute to medical knowledge. A man having this knowledge is not likely to cease to be a student, nor is he likely to be imposed on by advertising drug firms, which not only present him with unlimited samples, but have the audacity to tell him all about their therapeutical uses. For instance, the medical man who has been well grounded in the science of physiological chemistry is not likely to prescribe wine of pepsin or other alcoholic preparations of digestive ferments. Neither is he likely to be misled by any of the numerous newly coined words, which mean much or little, according to the way in which they are used. It seems to me that the only sure way in which the requirements for admission to our medical schools can be rigidly controlled and honestly adhered to is by the establishment of boards, no member of which has any connection with the medical school, which shall pass on all prospective medical matriculates. I am aware of the fact that this method is not wholly free from criticism. Such boards when composed of non-medical men do not always wisely discriminate between those subjects which best fit a man for the study of medicine, and those which, whatever their value may be in securing a broad education, are relatively of little importance in preparing one for medical studies.

It seems to me that there can be no question as to the desirability of every medical student having the ability to read either French or German, and if he can read both, his fitness for medical studies is greatly enhanced. It can not be denied that at present, at least, the most important contributions made to medical science come to us from German sources, and the man who must rely on translations in order to secure this information is, in the first place, delayed in acquiring the knowledge, and in the second place he is likely to be misled by errors in the translation. Did time permit I could point out numerous instances in which important articles in French and German have been misconstrued by the translator. There are two important sources of error in such translations. One of them lies in an imperfect acquaintance with the foreign language, and the other is due to the fact that these translations are often made by individuals who are ignorant of the subject matter involved in the contribution. Of the two languages, French and German, it is undoubtedly true that the latter is to the medical man the more important, and if knowledge of only one be demanded, German should be selected. The time may come, and I am inclined to think that it will come, when our own country will be quite abreast of Germany in scientific work, but such a time has not yet arrived, and the man who attempts to keep up with the times in a medical way without knowledge of the German language is, to say the least, heavily handicapped.

I suppose that no one will question the assertion that a fairly good grounding in the general sciences of biology is quite essential to the successful study of medicine. The preliminary work in this subject should cover a rather extensive course of reading and should always include a good drill in laboratory methods. In my opinion there is no subject so much neglected as a preparation for medicine as the study of physics and physical chemistry. A knowledge of physics is needed in the application of all mechanical means for the correction of deformities, for the treatment of fractures and dislocations, for the study of errors of refraction. and in the use of the microscope. ophthalmoscope. laryngoscope, x-ray apparatus, etc., and yet only a few of our medical schools demand any satisfactory preliminary knowledge of physics for admission, and still fewer of them offer the student any advanced work in this branch while pursuing his medical studies. In France and Germany the importance of physics to the medical student is thoroughly appreciated. A conversation which I had a few years ago with a clinical teacher in the University of Paris greatly interested me in this matter. He remarked that he could not understand how the best medical schools in this country could afford to neglect the teaching of physics. and added that his own faculty found it necessary not only to require an elementary knowledge of this subject for admission. but to furnish their students with advanced instruction in this branch while taking their medical course. In the German universities medical students take the same work pursued by their scientific colleagues in physics.

Physical chemistry is becoming of more and more importance, both in the study of physiology and pharmacology. It is true that the importance of this subject has been but recently recognized, and we must allow for a certain length of time necessary for medical schools to appreciate this new information and to provide means for giving instruction in accordance therewith to their students. The instruction in chemistry given to-day in many of our best medical schools is scarcely better than a farce. It embraces a semester's—possibly two semesters'—lectures with demonstrations covering the whole range of general, analytical, physiological, pathological and toxicological chemistry, supplemented by a brief course in the analytical laboratory. How can we expect the student whose knowledge of chemistry is limited to that acquired in such a course of instruction to comprehend the significance of Ehrlich's side-chain theory, or really to have any just comprehension of the nature of food principles, to say nothing of their assimilation and utilization by the cells of the body. A knowledge of the fundamental facts of general chemistry should be required of every applicant for admission to a medical school, and either before admission or after matriculation each student should be thoroughly grounded in the theories of organic chemistry and the general principles of physiologic chemistry, and to a certain extent in the methods of toxicologic investigation. I am aware of the fact that to do all of these things means to greatly increase the work which must be done by the medical student, and it is true already that there is no other profession proper preparation for which demands more time, energy and devotion and costs more money; but we must remember, as I have already stated, that there is no crying demand for more doctors, and we, the medical educators of this country, should have enough professional spirit to see that unworthy men do not enter our ranks. We must not mistake bigness for greatness, and we should have more pride in the quality than in the quantity of our products.

Shall we rely on our public schools to fit young men for the study of medicine? The public school system of most of the states in the union is probably better managed and is more creditable to us as a nation than any other state function. In the majority of the northern states, at least, this system was modeled during the early part of the nineteenth century after what was then known as the Prussian system. It embraces eight years of primary work, given for the most part by underpaid but well-qualified and conscientious women. From the primary grade the child enters the high school, in which he spends four years in acquiring additional knowledge. The high schools vary greatly both in the scope and the efficiency of their work. They are dependent on the wisdom and liberality of the school board, and, as a rule, they are free from the influence of political manipulators. Unfortunately this is not always true, but so far as my observation goes the high school is generally managed by fairly competent boards composed of men and women of more than average intelligence. In some few localities the political demagogue has not even spared this institution, and his corrupting influence has been felt in the selection of teachers and in the failure to provide proper equipment. It has been a part of my duty in the past fifteen years to know something in a general way of the high schools of the northwestern states. I have personally visited many of them and have frequently come in contact with teachers from a much larger number, and I have been frequently surprised at the excellence of these schools, even when situated in relatively small places and supported by relatively poor communities. As a rule, even in our larger cities the public school has better teachers, is better equipped and does better work than private schools in the same neighborhood, and a large proportion of our medical students have completed one of the two or three courses offered in one of these public schools. I take it for granted that no college belonging to this association will accept for matriculation anyone who has not had the equivalent of a high-school education, which, of course, means that the individual has had eight years in the primary and four years in the secondary schools.

Now the question arises, can we depend on these high schools to prepare young men for the study of medicine? In my opinion there are but few high schools which are sufficiently well equipped to prepare for the study of medicine, and we should demand additional instruction after graduation from the high school. In many of the high schools it still remains true that the classical course is the best offered. The teacher of Greek and Latin, who is frequently the principal of the school, is generally paid a higher salary than the teacher of the sciences, and in a general way the classical course is the best offered in our secondary schools. In our universities the classics are no longer paramount, but in the high schools the sciences have not, as a rule, received the attention they deserve. This, of course, will gradually be changed. On account of this condition of affairs I think that it will be found to be true that graduates of classical courses of our best high schools have had all the history and classics that can be reasonably expected of the man who intends to study medicine. At least they have had all that is necessary to the successful prosecution of medical studies.

In mathematics, graduates of such schools are, as a rule, slightly deficient, for mathematics in the classical courses of most of the high schools stops with plane geometry, and I am sure that every teacher of physics will agree with me that a knowledge of plane trigonometry is essential to the successful study of physics. However, the greatest deficiency among the graduates of classical courses in the high schools lies in the modern languages and in the natural sciences. The prospects are that more attention will be given to both of these in the future, but at present the average graduate of the average classical course in the high school has had inadequate preparation in the modern languages and in the natural sciences. I mean by this that in these branches he is not, in my opinion, prepared for the study of medicine, and he should be required to pursue these subjects in some well-equipped academy, college or university before he enters the medical school.

I should like very much to see this association make some move in the direction of advancing the requirements for admission. There has been no material advance in our requirements for the past ten years, and in this day of rapid progress ten years make a long time in which to lie dormant. I am inclined to think that unless some advance is made in the near future this association will not be able to hold together. Among its members there are schools whose requirements are much in advance of those of the association. These schools have been willing to continue as members of the association, hoping that they may be able to lend a helping hand to their weaker brethren, but they are not willing to stand much longer in this position.

I have referred to the desirability of placing the question of admission to medical schools in the hands of state boards, and I desire to say a few additional words on this subject. Of course, wherever this is done there are likely to be medical schools which will require more than the state board, but so far as I can see there is no objection to this. However, it must be admitted that such boards are likely to adjust their requirements not to the best medical schools in the state, but to the poorest, and this means that the latter receive a certain official recognition which misleads medical students and may induce them to go to an inferior school rather than to one of higher grade. However, I think that so far as we have experience with this matter in the United States the establishment of a board for the examination of medical matriculates has ultimately led to advancement in the requirements. Temporarily harm may be done. I believe that it is true, but on this point I have no exact information, that the establishment of the Ohio board has led to a great decrease in the number of medical students in the medical colleges of that state, and a corresponding increase in the number of Ohio students attending inferior colleges in other states. However, the time will probably soon come when the other states will have similar laws, and this matter will adjust itself. It is barely possible that a good school may be a little slow in advancing its requirements so long as it is able to throw the responsibility for admission on the state board, but after a while the good school will get ashamed of doing this and will advance its requirements whether the state board does so or not.

In conclusion, I wish to repeat that it seems to me that this association as a body is moving slowly in the advancement of medical education. Let us be up and doing and show some evidence of growth. The standing of our profession in the next generation and its influence on the nation will depend on those who are now entering on the study of medicine under our guidance, and we, as the medical educators of this country, will be held responsible, probably above all others, for the class of men who will constitute the profession of the next generation.

REQUIREMENTS FOR ADMISSION TO MEDICAL COLLEGES.[*]

E. A. de SCHWEINITZ, M.D.
Dean of the Department of Medicine of the Columbian University.
WASHINGTON, D. C.

A man who has not had a biologic training may become an excellent physician, although he will have to work harder to make up deficiencies. Some of the biologic work if not possessed by the student on entrance might well be included in the first year's course. It would certainly be a great advantage if more comparative work was required throughout the regular medical course. This could often well be done by eliminating some of the special studies which are properly postgraduate. In fact, the entire medical course could be remodeled to advantage.

It is not the business of a medical school to graduate specialists, nor is it the business of a medical school to make the course of such a character that only a few can succeed in accomplishing the required work. We should give to each student a good, general, solid groundwork and afford him an opportunity to determine in his own mind the particular line to which he is best adapted.

So far as the Latin requirement for entrance is concerned, I think that in many cases the substitution of French or German might be allowed. To require these languages for entrance, however, would be unnecessary, while a certain amount of one or both of them might be demanded before graduation.

To the investigator and specialist a knowledge of these languages is invaluable. At the same time there are excellent abstracts of important foreign literature promptly issued by American journals which make the language requirement of less importance than formerly. Even if the practitioner has a knowledge of these languages, unless he is one of the fortunate few located in a large city, or near a large medical library, he has but little opportunity to profit by this knowledge without subscribing for a number of expensive journals. If he does this he will usually find that the half-page abstracts of the article contain all the information that he desires.

I do not wish to be understood as undervaluing the advantage given by a knowledge of the modern as well as the dead languages, as no one could appreciate more thoroughly how useful they are in practical work. We should point out to the student the advantage which will accrue not only from a good knowledge of French and German, but also Spanish, at the present time of great practical value. We should encourage him to round off his medical equipment by acquiring a useful knowledge and not a mere smattering, such as is often given him in many schools and colleges at the present day. We wish to make a man's training as complete and thorough as possible, and give him the basic work, after which he will be able to recognize his own special abilities and select the line in which he can best succeed.

---

[*] Read before the Association of American Medical Colleges, 1902.

For several years we[1] have refused advanced standing to graduates in veterinary medicine, dentistry, pharmacy and literary colleges, although the constitution of the association permits such recognition. Such graduates are, as a rule, not better able to cope with the medical course in a shorter time than those who lack a college training. A high-school graduate usually makes a better student than the average college graduate. The law of New York forbids the recognition of colleges that grant advanced standing for the degrees mentioned and none should be allowed.

Certain medical studies should be allowed to count towards an A.B. degree. An A.B. degree should not be allowed to count towards a medical degree.

No college, a member of this association, should receive a student from another school unless he holds a special letter from the dean of the school from which he comes. During the past year students have come to me from other schools with clean certificates, which on inquiry proved to be falsified. Some system should be adopted which will effectually prohibit such fraudulent attempts.

REQUIREMENTS FOR ADMISSION TO MEDICAL SCHOOLS.[*]

JAMES RUSSELL PARSONS, Jr.
SECRETARY BOARD OF REGENTS.
ALBANY, N. Y.

It will aid us in discussing this topic to review briefly the quantitative requirements now exacted:

1. In accordance with statutory provision.
2. By individual medical schools.

In the state of New York a preliminary general education equivalent to graduation from a four-year high-school course after a completed eight-year elementary course is prescribed by statute as the minimum standard for license to practice medicine. Quantitatively this standard approximates that demanded in Continental Europe. Qualitatively it leaves much to be desired. The defects are being remedied, as I shall show later.

New Hampshire, Ohio and Vermont have similar requirements, but they are not as rigidly enforced. Wisconsin demands the equivalent of admission to the junior year of an accredited high school. Delaware, Maryland, New Jersey and Pennsylvania prescribe a "common school education," Louisiana "a fair primary education," Illinois and Iowa less than one year of high-school work, Maine and Virginia evidence of a preliminary education, Arkansas a good literary education where a licensing examination is required, Rhode Island a high-school diploma or its equivalent under the same conditions. In remaining political divisions laws and rules are either silent in this respect or so indefinite as to be of little value.

According to the latest available catalogues Johns Hopkins and Harvard exact a college course for admission; Western Reserve, the completion of the junior year in college (really, as appears later, Harvard should also be in this class; admission to baccalaureate courses, however, is higher than elsewhere); the University of Minnesota, the completion of the freshman year; 17, 9, 14 and 90 medical schools require respectively four, three, two and one year of high-school work; 11 demand a grammar school education; in three the requirements are indefinite.

At present only four medical schools in the United States exact more in quantity than is represented by the New York state medical student certificate. Later, in speaking of qualitative requirements we must also include in this roll of honor Columbia, Cornell, Syracuse, University of Michigan and, after 1904, the University of California.

In answer to recent inquiries 79 of the 80 medical schools of the United States giving definite information on the subject report that the New York state medical student certificate is accepted at its face value for entrance.

There has been substantial progress since 1900, but it is still true that when medical schools conduct their own entrance examinations the tests are often mere matters of form, even though the standards appear satisfactory on paper.

The five subdivisions of this topic call for a discussion of qualitative requirements. Up to this point we have spoken entirely of quantitative requirements. I think, however, that we shall get a clearer conception of the quality of the work that should be required by approaching the subject in this way.

A satisfactory uniform statutory requirement is impracticable at present, owing to varying conditions as to density of population, educational advantages and general development. It should be comparatively easy, however, with united efforts on our part, to bring about much more satisfactory conditions than those at present prevailing.

It is highly desirable that there should be a sufficient degree of uniformity in admission requirements to medical schools so that, as in other countries, students could go without inconvenience from one school to another for special lines of work.

In graduate schools it would seem sufficient to make a minimum requirement, as at Johns Hopkins, in languages, physics, chemistry and biology. It appears that Harvard, though nominally requiring college graduation, has been in the habit of accepting master degrees, which may represent nothing, or bachelor degrees, like the Spanish Bachillerato or the French Bachelier, which stand for little in advance of high-school graduation. Then, again, the combined course as at the Lawrence Scientific School and the medical school may be completed in seven years.

Graduate schools probably without exception will continue to be parts of great university systems, where work is organized on very broad lines, thus making it possible to vary to a considerable extent the requirements for an M.D. degree.

Next in order come those schools that demand for admission to the four-year medical course one, two or three years of college work. At present there are only two schools in this class, or three including Harvard. Here there is an excellent opportunity for work in Latin, French and German, physics, chemistry, biology and mathematics, to make good deficiencies in high-school courses.

We now reach the most important class, the schools that follow the New York statutory requirements in demanding for admission a four-year high-school course based on an eight-year elementary course. I say the most important class, though it now embraces only 17 schools, because this is the highest standard that will be obtained by a large majority of those who study medicine.

[1] Department of Medicine, the Columbian University at Washington, D. C.

[*] Read before the Association of American Medical Colleges, 1902.

screw clamped a second plate on the fold of tissue. This instrument was modified by Redfern Davies for large hernias, making a divided invaginator.

Leroy d'Etiolles and Langenbeck maintained the original fold by pressure forceps, the latter contrived to produce an extensive slough of the anterior fold by the prolonged pressure of the forceps. The cicatricial plug resulting occasionally produced a cure.

Agnew and White invented instruments which were on the same order as that of Wützer, differing, however, in that no instrument was left to produce pressure. Thread was passed through the tissue near the internal ring, which closed the canal. Mosner used a trocar armed with a thread attached to a seton which was passed up into the canal. The seton was left for three or four weeks. Gross, Rothmund, Schlosser, Ratier, Riggs and others also adopted this plan for a time.

Credit is due Dr. John Wood, who first recognized the principle which governs the cure of this defect in Nature, by sutures or approximating the pillars of the ring with pins, as in a hare-lip operation. Prof. S. D. Gross, in 1861, in operating for a strangulated hernia, performed a similar operation with success. A description of this operation is instructive, as it shows what erroneous ideas were prevalent at that time about the union of wounds. It was thought necessary for good, firm union that a certain amount of edema and ulceration was desirable. Dr. Wood, after having operated on 200 cases, gives 50 as the per cent. of cures in adults and 75 under puberty. A truss was advised by the doctor to be worn several months after the operation.

Dr. Van Best and J. Chisolm about this time did an operation, approximating the pillars with a buried salmon gut. Dr. Greenville Donell up to 1876 had performed 96 operations with 80 cures by the subcutaneous method, using silver wire twisted over cork.

William Spanton, 1879, contrived an ingenious method of approximating the tendons and muscular boundaries of the canal. Through an incision made over the mass the index finger was introduced to shove up the sac. An instrument resembling a cork screw alternately penetrated the opposite boundaries of the canal. This brought the walls together and held them for two or three weeks until union was firm.

The direct method of S. D. Gross, who was the first to cut down on the sac, freshen the edges of the ring and suture them together with wire, was soon adopted. The sac was variously disposed of, some tying it off and removing it, others simply tied it and inverted it within the abdomen. It seems strange that the simplest, most surgical and most beneficial operation of all for the cure of hernia should remain undiscovered so long. It is a natural outcome, perhaps, of the careful study of anatomy of the hernial region, the recognition of Nature's fault in not closing this opening to the abdominal cavity, and the possibility of remedying what Nature should have in the evolution of this region.

The ultimate success of an operation is of the utmost importance to the patient. Surgeons are obliged to await the verdict of their patients before they conclude that any special operation is a success or not. The profession has had a harder time to fight popular prejudice against operation for rupture than any other surgical procedure. The public has a perfect right to this prejudice because of the evil results which have occurred in the past. Failures have been so frequent that a perfect result was not always anticipated. Therefore, physicians themselves chose to fit a truss instead of advising a radical operation. The quack advertised extensively to cure rupture without an operation. There still exists large truss-fitting establishments which are too frequently visited by the general public, who are anxious to adopt a simpler method of relief and escape the risks which they imagine are connected with a surgical operation. Nearly every drug store makes a specialty of harnessing up these afflicted persons with all sorts of appliances.

The careful and successful work of the modern surgeon, however, is beginning to bear fruit in this class of cases especially. Thoughtful, scientific men have studied the problem of hernia so that we know an operation will cure if certain principles are observed. The operation is safer for the patient than to run the chances of strangulation, notwithstanding he may wear a truss.

There are few of us who have not seen a hernia return on account of infection, or from weak union, due to sutures absorbed too rapidly. The Johns Hopkins followers have the utmost confidence in the buried silver wire. Some patients are compelled to have these sutures removed later. The disciples of Marcy tell you there is nothing so good as kangaroo tendon. This also is not to be relied on, as has been found by many who have used it. Silk and silkworm gut is not absorbed. The continual irritation may result in infection directly through the lymphatics or blood current. So-called dry, sterilized catgut is frequently absorbed before union occurs, and is not always sterile. A nidus is formed in which micro-organisms grow more readily. The silver catgut has at times given endless trouble. We may offer the same objection to chromicized catgut. The iodoform gut is the least objectionable of all; it is more sterile, lasts longer than the dry, is more elastic, and, on the whole, is a very good suture, yet failures result in its use occasionally.

The pubic region is the most difficult portion of the body to render sterile, on account of the numerous sebaceous glands and hair follicles present. Owing to this fact infection is more frequent in this region than elsewhere. When sutures are tied tightly, or there is much tension on the opposed tissue, the skin does not resist the strain, but is strangulated or cut through. This occurs likewise in the deeper tissue. If there are any infectious micro-organisms at these points a deleterious inflammation arises.

Where there are so many different ways of performing the operation and such a variety of suture material used, our conclusions are that failure or unsatisfactory results occur, otherwise we would all adopt one special method. It would seem that it is not altogether the fault of the suture material if properly sterilized as much as the manner in which it is used. An analysis of a number of cases of relapse and failure leads me to suggest the following reasons for failures:

Too vigorous and rough scrubbing of the parts before operation with the idea that it is necessary for cleanliness. This produces minute pustules of the skin just prior to the operation.

Careless preparation of the parts and the hands of the operator, or because the operator and his assistants have not worn rubber gloves.

Because operations are performed on patients suffering with some constitutional or other local disease.

The employment of sutures that are absorbed too readily.

The use of sutures that are improperly sterilized.

Lack of identification of tissue, and necessarily improper approximation of the opposing structure, especially in cases where there is a very poor development of the fibers of the internal oblique and transversalis.

Too great tension from vomiting or pressure of gas from within.

Incomplete dissection of the sac and its ligation.

Because sutures are tied too tightly, causing pressure, necrosis and stitch abscesses.

The use of non-absorbent sutures which, being left, irritate the structure and result in infection.

Excessive handling of the parts at the time of operation, causing destruction of tissue, necrosis, sloughing and abscess.

The causes of inguinal hernia may be few or many. The tunica vaginalis may not have contracted completely, and there remains a slight pouch at the internal ring into which the viscus may enter and gradually forces its way into the canal. Increased intra-abdominal pressure from ascites or gas, straining from phimosis, constipation, stricture, prostatic hypertrophy, calculæ, coughing, etc., are exciting causes.

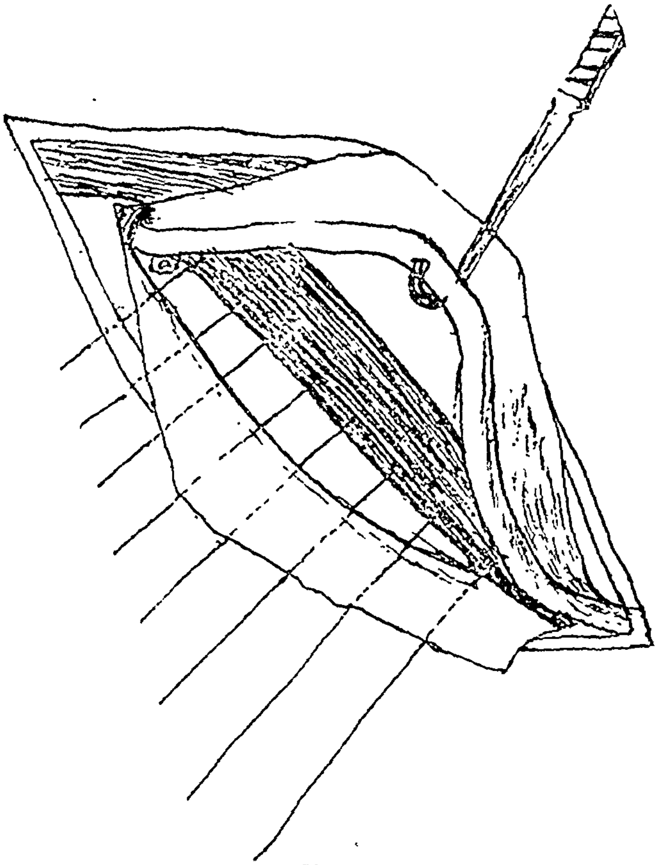

Figure 1.

When the tunica vaginalis remains open, a congenital hernia is inevitable. Weak muscular or aponeurotic development around the rings or canal are potent causative factors. This is emphasized by Dr. Ferguson in an article entitled "A Typical Operation for the Cure of Oblique Inguinal Hernia." The lack of development of the original fibers of the internal oblique and transversalis, he believes, is a most important cause of hernia and relapse.

The first symptoms of a hernia develop gradually. A weakness and dull pain is felt in the groin, or sick feeling and a weight may be present, especially noticed in walking or standing, *until the bowel enters the canal* and can be felt, first as a bubonocele and later as a complete or scrotal hernia. A strangulated hernia occurs where the bowel is rapidly forced down through the external ring. The pillars of the ring contracting on the mass, impedes the circulation of the protruding viscus, and causes greater enlargement from congestion. Inflammation and edema of the entire mass is present, making a reduction by taxis difficult or impossible.

The treatment may be divided into palliative and the radical. The palliative consists in wearing a good-fitting truss over the internal ring. A great many good trusses are now made which enable the wearer to get around with comfort, and which permit the patient to perform almost any work required. Yet there remains the danger of strangulation that may come on because of the weakness of the support from age and wear. The history of nearly every strangulated hernia is that the patient has continually worn a truss before the accident happened.

We can not blame persons for choosing this form of treatment when they may have knowledge of friends who, having had an operation, have the hernia return *and are unable* to wear a truss with the comfort they did before the operation, on account of cicatricial tissue formation, exaggerated because of a complicating abscess.

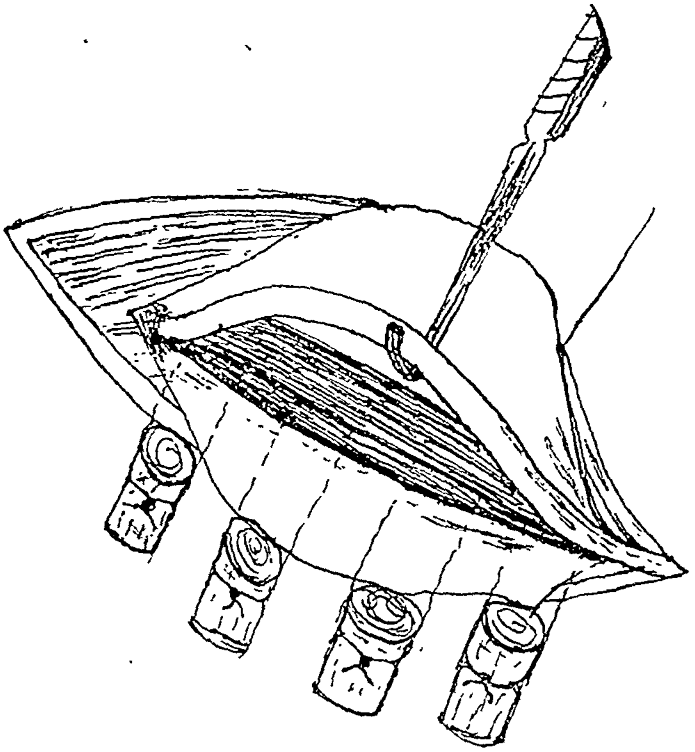

Figure 2.

The modern operations which have been devised for the radical cure of hernia are numerous. All have for an object the ultimate retention of the abdominal contents, by closing the breach with as firm a wall as possible, consistent with a healthful state of the cord and testicle.

We have few criticisms to make, if any, as far as appearance of the operation at the time is concerned. It seems, however, that, generally speaking, there are too many relapses.

A suture is useful to keep the parts in apposition until union has occurred, and until that union is firm enough to resist the pressure of the internal organs.

Any substance which has to be absorbed by the tissues lessens their vitality and serves to produce a culture media, in which micro-organisms may grow.* A non-absorbable suture material that can be positively sterilized by boiling has no effect on healthy tissue if properly placed and left for a few days. Any substance foreign in nature which can not be absorbed if left in the soft tissue permanently often acts as an irritant, which may cause pain or results in infection. The epidermis albus grows more rapidly where there is necrosis of the tissues, at the location of sutures.

The average surgeon is liable to tie sutures too tightly, and especially in doing an operation to cure a hernia. The idea uppermost in the mind of the operator at the time is to bring the tissue into such close proximity that no viscus can crowd through the wound while healing. This defeats the very object of the operation often by strangulating the tissue of the deeper or superficial layers. It results in pressure necrosis, a nidus for infectious germs, and consequently a deep or superficial abscess. Add to this a suture material that is absorbable, and these factors are augmented. A non-absorbable buried suture prolongs the healing when there is infection, and it acts as a guide for the invading germs to other would-be unattacked tissue, through which the suture passes. The experienced operator may avoid this catastrophe because he is able more accurately to gauge the tension of his sutures.

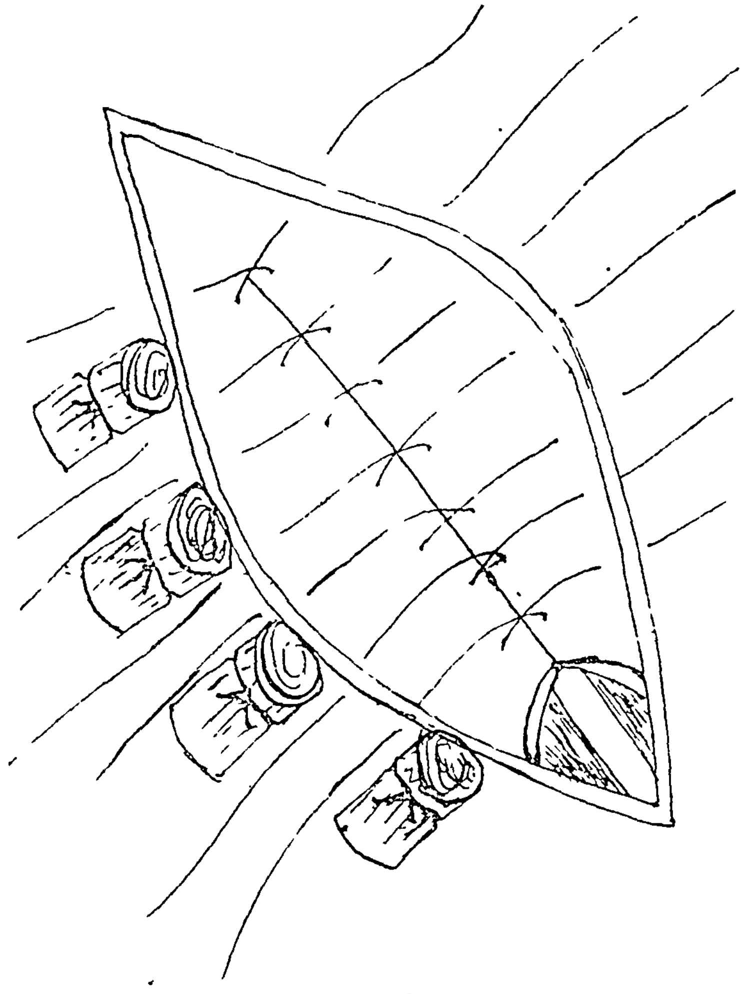

Figure 3.

A roll of sterilized gauze, to take off the force of too tight suturing and distribute the pressure, affords the average operator the protection and success of the more experienced surgeon. This method of operating for inguinal hernia is not new, nor do I claim that it gives better results in every instance. I do think, however, that the result is more satisfactory to the occasional operator for reasons above stated.

In preparing my patient, I prefer to shave the parts the morning of the operation. In doing so, we avoid infected areas or vesicles which may result when the shaving is done the previous evening or before the parts have been thoroughly cleansed. The time intervening between the evening and morning of the operation favors a greater multiplication of micro-organisms. The bowels are thoroughly emptied and subsequently kept free from gas accumulation. This lessens the internal pressure.

An ordinary incision for a Bassini operation is made. The aponeurosis of the external oblique is slit up to the point opposite the internal ring. The fibers of the internal oblique and transversalis muscles are divided by blunt dissection, thus opening the inguinal canal. The internal oblique and transversalis muscles are found closely connected. They are not separated, but the aponeurosis of the external oblique is carefully and thoroughly removed from the internal oblique. The lower portion is dissected down to Poupart's ligament and the transversalis separated from the peritoneum. Such careful dissection and positive identification of structures shows any deficient development and is an important help in securing direct apposition and firm union. The cord is now raised and silkworm-gut sutures are introduced to the outer side of the incision, passing through the skin, Poupart's ligament, the internal oblique and transversalis, on the inner side of which the loop is made. The needle, re-entering the transversalis and internal oblique, passes through Poupart's ligament and comes out through the skin to the outer and lower side of the cut, near the point of entrance. (Fig. 1.) From three to five sutures are similarly introduced. These sutures pull the internal oblique and transversalis below the shelving edge of Poupart's ligament, and are observed to make a firm barrier against any internal force. A double support is formed and any defect is corrected. The sutures are then tied over rolls of sterilized gauze. (Fig. 2.) The spermatic cord then rests on the internal oblique. The external oblique is then closed over the cord. Interrupted figure-of-eight sutures are introduced, bringing the external oblique in apposition with Poupart's ligament. (Fig. 3.) They also approximate the skin, and are tied over a gauze roll. (Fig. 4.) The sutures are usually left two weeks.

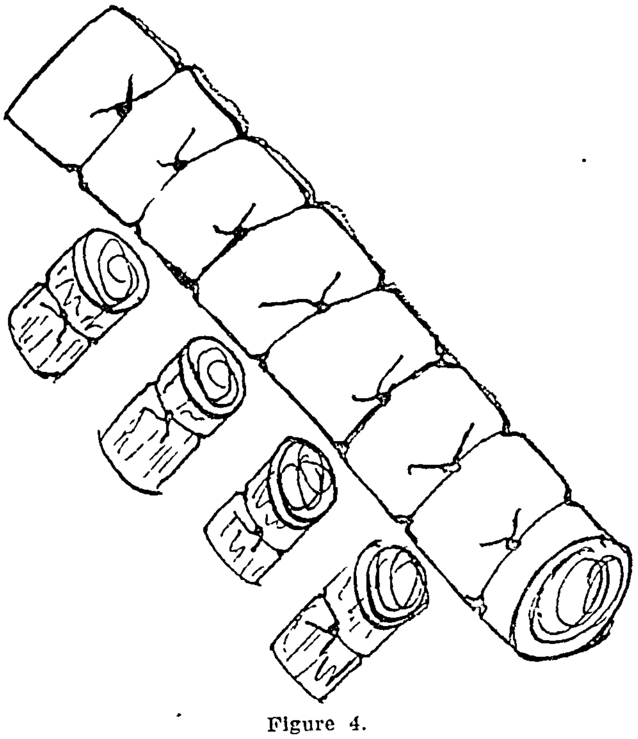

Figure 4.

The conclusions for this operation are:

1. There are no sutures for the tissues to absorb.

2. There is no additional culture media in which infectious micro-organisms grow and cause deep abscesses.

3. There are no buried, non-absorbable sutures left to irritate the tissues and cause further trouble.

4. There is no necrosis from tight sutures, therefore few, if any, stitch abscesses.

5. The gauze rolls act as elastic cushions which prevent scars from the sutures.

6. The operation completely closes the breech and makes a firm wall.

7. All sutures, after serving their purpose, are removed, leaving only the natural supports.

302 Pillsbury Building.

EVOLUTION IN THE TREATMENT OF CANCER OF THE RECTUM.*

C. H. MAYO, M.D.
SURGEON TO ST. MARY'S HOSPITAL.
ROCHESTER, MINN.

Certain definite results are desired in operations on cancer of the rectum, namely, permanent cure, low operative mortality and a controllable anus, or its best substitute. These results are modified by location, stage of progress and the age and condition of the patient.

The gradual evolution which has led up to the treatment in vogue to-day makes an interesting study. Previous to 1870, operative treatment on cancer of the rectum was but limited in extent, and only performed by the great surgeons of that time; in fact, it was almost limited to nothing, palliation, and lumbar colostomy. Yet the results of these methods compared most favorably with radical operations.

At present a diminishing number of patients present themselves at such a late period that they fall within the limits of this type of surgery. Inguinal colostomy has replaced the lumbar. During the next ten years to 1880 there was a marked advance in all surgery. Instead of there being but a few surgeons with initiative, a large number were making active scientific progress. New and often similar methods of procedure were devised by surgeons widely separated and each without knowledge of the investigations of the others. This progressive spirit, which fortunately continues, resulted in many operations bearing the names of two and even three surgeons who had advanced the principles at about the same time.

In rectal surgery there were developed the circular enucleation of Lisfranc, perineal excision, Deffenbach's incision anterior and posterior to the anus, and the great advance made by Kocher in 1874, when he excised the coccyx to gain access to the rectum. Many surgeons still contend that by this method sufficient space is secured to accomplish the removal of all cases which should be attacked from below. Verneuil also deserves credit for removal of the coccyx at this time.

The difficulties which were most marked during this period were sepsis, which could not be avoided, stricture or incontinence from the loss of the anus, and recurrence, the most serious of all as well as the most frequent. The recurrence most commonly seen was probably from incomplete removal and at times undoubtedly from direct inoculation of the wound by the cancer. The direct inoculation of wounds by both cancer and sarcoma cells is a condition well understood to-day, and many operators to a certain extent avoid this complication by excising the anal and low-lying cancers of the rectum with a Paquelin cautery; others, when the cancer unavoidably contaminates the wound, apply carbolic acid, followed by alcohol, to prevent germination and absorption. Surgically considered, this was an epoch of drainage.

During the years from 1880 to 1890 was developed the germ theory which revolutionized surgery and medicine. This period was one of antisepsis and drainage. Operations in all lines of surgery became more radical. The perineal methods were made more complete. Rehn, a German, and Campenon, a Frenchman, at about the same time brought out the vaginal route for certain cases of rectal cancer, a method which has been so highly developed and popularized by Dr. J. B. Murphy. Steinthal removed invaginating cancers by means of an elastic ligature. In 1883 Volkman opened the sacral canal in an operation for sarcoma. Kraske, at that time his assistant, noticing that no harm resulted, was led to develop his sacral excision method of operation. Now all varieties of sacral exposure bear his name, although variously modified by Bardenheuer and others in being more extensive, by Heinecke, Roux and Rehn and others in preserving the bone by a temporary resection, and by Zuckerkandl in making a parasacral incision.

The difficulties which arose were from shock, which usually meant loss of blood; from peritonitis, as two-thirds of the Kraske operations necessitated opening the peritoneum; and from the attempt to perform radical operations on inoperable cases, as the damage to the bone, loss of blood and open peritoneum were necessary by this method, before the operator knew fully the extent of the disease. The anus had usually been sacrificed; now, where possible, attempts were made to preserve this outlet. Various methods of uniting the distal and proximal bowel were devised. Suture methods frequently failed, or partially failed, leaving permanent fistulæ, as did all methods much too often, were they plastics, Murphy's button or invagination. The Hochenegg method of invagination by passing the proximal end through the anus and suturing to the skin, was later modified by removal of the mucous membrane of the anus. One of the best methods was to draw the proximal bowel through the anus, which was inverted, and make a circular suture union, which is replaced within the sphincter. Lange made a half circular incision anterior to the anus, admitting of its being depressed two inches to reach the proximal end. With the anus saved, it was often found that the extensive mutilation had permanently injured its nerve supply, and when saved intact, that it required the levator ani and internal sphincter to render it functionally perfect in preventing the sudden escape of gas and thin feces.

Gerster states that practically all of these methods of union result in primary or secondary stricture, which is from the character of the surrounding tissue. Most frequently it was found that so much bowel had been removed that a sacral anus was necessary. When an artificial anus is determined on, Witzel, Wilms and Rydygier recommended the division of the glutinus maximus, made at one side of the sacral incision and the suture of the bowel end to a skin incision, thus gaining muscular compression. Gersuny rotated or twisted the bowel sufficiently to close its lumen and sutured. Still, in spite of all methods, only approximately 15 per cent. of these patients secure anything like a controllable anus. The incontinence which ensues is not comparable to those cases of torn or paralyzed sphincter or sacral fistula, as such cases still have the seventeen-inch loop of sigmoid in the pelvis—whose value as a fecal container was *pointed out by Wyeth—with the natural constriction* at the top of the rectum to control the fecal current. Yet such cases presenting themselves for relief are often considered as bettered by an inguinal colostomy. The local recurrence, which is so frequent, often causes such a degree of obstruction as to require a later colostomy, a condition which we met in three cases. The direct channel of the colon from the splenic flexure to the outlet leaves *no space for a fecal container and renders* closure a question of hydrostatics in these operations.

---

* Read at the twelfth annual meeting of the Western Surgical and Gynecological Association, held at St. Joseph, Mo., December 29 and 30, 1902.

The last decade has seen an advance in methods derived from an analysis of the mortality and failures in the past, and the gain has resulted in the present thoroughness of surgery, and asepsis for antisepsis. The block removal of the rectum and glands where possible from below and in high location of the cancer, the combined abdominal and perineal method of removing rectum, glands and all malignant tissue *en masse,* is the new surgery for cancer of this region. This method is merely the application of principles of the general surgery of cancer, regardless of location, as exemplified by Halsted's *operation for the removal of cancer of the* breast. It is probable that the removal of cancer of the rectum in the past compares well with the removal of cancer of the breast before the radical operations were made on the lymphatic system, with the exception of the former being in a more septic region. The combined abdominal and perineal method is now advocated for high rectal carcinoma by the pioneers in rectal surgery, Kocher, Kraske, Gaudier, Quenu, Trendelenberg, Abbe, Weir and numerous others.

Cancer in the young is much more serious than in the old, both as to rapidity of growth and early involvement of the glands, although it is frequent that the glands *are only involved late in the disease.* The average life with cancer of the rectum is given as from one to two years; this may be true in the young, but in the old, if we approximate the commencement, it must often exceed double this length of time.

Allingham considers the removal of cancer, in patients under 45 years of age, as unfavorable; between 45 and 60 years, as more favorable, and over 60 years, still more hopeful. Statistics change from year to year with the ability of the operator, whose judgment increases from his mistakes and failures, and whose ability to select a justifiable operation for rectal cancer, according to the extent, location, fixation, glandular involvement, cachexia and age, *or invasion of neighboring organs,* such as vagina, uterus, prostate or bladder, becomes more and more reliable. Therefore, statistics mean more to the surgeon who makes them than to any one else. Kraske's mortality in the first ten cases was 40 per cent.; this he has now reduced to less than 10 per cent. The average mortality is still somewhere between 15 and 18 per cent. Hochenegg, in 121 sacral operations, had 5 per cent. mortality and 25 per cent. cures.

Kroenlein (Zurich) answers three questions: mortality of operation, *recurrence, and functional disability;* 881 cases show that the sovereign method is extirpation, 80 per cent. survive, 14 per cent. are lasting.

The functional result is best when possible to preserve the anus and sphincter. In the discussion Kraske expressed satisfaction in his 120 cases of sacral method, but thinks the combined abdominal sacral method more radical. Gaudier of Lille begins with a laparotomy, and by section *of the bowel at the iliac fossa* makes an inguinal anus. The peritoneum is cut from the sides of the rectum and below and the rectum forced down by blunt dissection as far as possible, the peritoneum closed and the operation completed from the perineum. Gaudier claims the method is of aid in: first, complete extirpation of the cancer; second, removal of lymphatics; *third, the possibility of complete asepsis;* fourth, no bony mutilation; fifth, the artificial anus is more supportable and more easily supervised than in the sacral region.

Quenu separates the cancer by sacral operation first, then, if necessary, makes an abdominal incision and inguinal colostomy. Chalat of Toulouse practically performs Gaudier's operations.

In our own work we were compelled some two years *ago, by the necessities of two cases, to operate from the* abdomen in one and from the abdomen and perineum in the other. During the past year we have operated on four cases in which the combined operation was planned previously. The operation, as described by Gaudier, we *modified in regard to the colostomy. Through a median* opening the sigmoid is double clamped and cut at a point as low as possible, yet well above the cancer, then *invert the mucous membrane and close both ends with a* purse-string suture. This renders the remainder of the operation aseptic. The superior hemorrhoidal artery is ligated and the proximal sigmoid segment is loosened and brought through a McBurney gridiron incision in *the iliac fossa. This incision is peculiar in the skin* incision, being at a distance of one and one-half inches to one side of the muscle separation. The end of the bowel is brought out and sutured to the skin incision; also a few sutures unite the bowel to the peritoneum at *the point of exit. This preserves the loop of sigmoid as* a fecal container. Prolapse is prevented by sutures from within, the muscle separation and sigmoid curve of outlet with skin covering for compression give a fairly controllable anus at a position where the patient is enabled *to give it proper attention.* If the median incision discloses an inoperable condition, that is, inoperable from a curative standpoint, from metastasis in glands or neighboring organ involvement, an inguinal colostomy is made and the median wound closed.

Colostomy, as usually performed, has been by the lifting of a loop of sigmoid through an abdominal iliac incision. The loop is supported by one of the various *methods and the bowel is sutured to the peritoneum and* skin, forming a true funnel-shaped hernial opening in the abdominal wall; that is, skin and peritoneum in contact. There was often prolapse following late after operation, to avoid which the loop of sigmoid was caught *up at such a point* as to render the descending colon under slight tension in the wound, thus rendering the *closure of the outlet a question of pressure against a descending flow.* The best operation is that of Mixtere, in which the sigmoid loop is drawn through a McBurney *gridiron incision,* and a rectangular skin flap pedicle attached at one end is drawn through an opening in the sigmoid mesentery. The skin flap is sutured back to place at the free end and sutures applied to the bowel, peritoneum and skin. When the loop of bowel is cut *through, this skin covering* of the bowel acts as a valve when compressed by a pad.

To sum up the main objections of the past, we have:

1. Ineffectual removal with local recurrence so common in the perineal type.
2. The extensive mutilating character of the Kraske before operative conditions were known.
3. The frequent *failure of all methods* of union of proximal and distal portions of the bowel, which, when united and anus saved, *with the destruction of the levator ani* and internal sphincter, represented but one-third of the controlling apparatus of the bowel.

4. The frequent formation of stricture either cicatricial or cancerous following operation necessitating inguinal colostomy.

5. The straightening and tension of the sigmoid destroyed it as a fecal container.

6. That sentiment and not chance has proven the main reason for continuing to place an uncontrollable anus in a comparatively inaccessible situation.

The gain in the combined operation has been in a selection of the operation to the case, either radical removal *en masse,* with all glands, fat and connective tissue or a colostomy for palliation. The retention of the sigmoid as a fecal container and the peculiar formation of the anus, giving a fair degree of control in an accessible situation.

SOME REMARKS ON SCLEREMA NEONATORUM,

WITH REPORT OF A CASE WITH AUTOPSY.

E. R. STILLMAN, M.D.
TROY, N. Y.

Sclerema neonatorum is a rare disease. Up to the present time I have been able to find but seven cases reported in America, and a careful review of the literature of Europe affords but comparatively few examples of the strange condition. The obscurity of the etiology of the malady and the scarcity of clinical reports of cases with autopsies, as well as the meager and unsatisfactory descriptions of the same found in most text-books, render doubly interesting the report of a typical case, and afford an excuse for a perhaps too lengthy description of the clinical picture of the disease.

Uzembezius, a physician of Ulm, in a work entitled an "Ephemeris of Natural Curiosities," published nearly two centuries ago, described an infant, born at term, which from top to toe became rigid and cold, resembling a piece of flesh dried by fire. This is regarded as the first recorded case of infantile sclerema, and it was at that time ascribed to maternal impressions, since the mother of the baby had spent much time in the churches, worshipping the images and statues found there.

To Underwood, however, an English physician, belongs the credit of having first recognized and described the disease, a description, too, so vivid and so true as to have left little to be added or to be taken away. His observations were particularly noted in France, and the condition most thoroughly studied there, although for many years it was confounded with a very similar condition, edema neonatorum. This disease presents many features in common with sclerema, but differs in so many respects as to leave little doubt that they are essentially separate and distinct. Andry (1781), Leger (1825), Billard (1839), Villaix (1849), all recognized, studied and described the malady and developed many and ingenious theories to account for it. It remained for Parrot, however, the brilliant Parisian pediatrist, to establish the fact that sclerema neonatorum was a distinct clinical entity, although the conclusions of this observer have been somewhat modified by the studies of more recent years.

The subjects of this disease are usually found among the premature, weakened, poorly-developed infants of the foundling asylums. Cases occurring in private practice are exceptionally rare, although Parrot cites cases developing in well-nourished, robust and well-fed infants. Whether or not hereditary syphilis plays a rôle in the etiology is still a disputed point. Cases have been reported in which improvement or even recovery has followed treatment by mercurial inunction, but there is room for much skepticism as to the correct diagnosis in such instances. Within the past decade attempts have been made to isolate specific bacteria and to demonstrate that they were responsible for the development of the disease, but the number of observations in this direction is as yet too few for any definite conclusions to be deduced.

The affection, which is characterized by an induration of the skin and subcutaneous tissues, does not, as a rule, develop immediately after birth, but the symptoms are first noticed within the following seven to ten days, although according to Hennig they may be delayed as late as the seventh month. It is doubtful, however, whether such late developing cases should be regarded as instances of genuine sclerema neonatorum, but that they should rather be classed with scleroderma. In the first place, they do not correspond clinically with sclerema, they more frequently end in recovery and show a tendency for the induration to occur in isolated areas. It seems reasonable, therefore, to consider those cases which develop late as scleroderma infantorum corresponding to scleroderma adultorum, than to regard them as instances of true sclerema neonatorum as described by Underwood.

The symptoms may develop suddenly with no particular warning, may follow or complicate an acute disease, such as pneumonia, or they may be preceded by a variety of indefinite signs of general disturbance, such as vomiting, diarrhea with greenish stools, obstipation, convulsions, etc. The infant may become thin and emaciated, the eyes sinking into the orbits, the skin of the face taking on a sallow tint, becoming wrinkled, wizened, like the face of a little old man; or the disease may appear so suddenly that when first seen the characteristic induration may be the first and foremost symptom to which our attention is directed.

With such an onset the changes in the skin, which represent the essential feature of the disease, develop. In the invaded region the skin becomes swollen, shiny, losing its normal folds, appearing as if under tension, very like edema, but harder, firmer, showing little or no evidence of pitting on pressure. The elasticity and suppleness of the skin are gone; it is no longer possible to pinch it up into folds by the fingers; it is cold, clammy, greasy to the feel, for all the world like the outside rind of a ham. It is hard, as if glued down to the subcutaneous tissues; it is impossible to slide skin over subcutaneous parts, skin, muscle and underlying bone appearing to be fused completely together.

The color of the invaded areas varies from a dirty yellowish jaundice-like color to a livid blue black, the tints being comparable to the array of colors afforded by an area of ecchymosis slowly absorbed. The temperature of the part is always much reduced.

The amount of surface of skin involved varies within wide limits in different cases. It may remain circumscribed, death occurring to effectually check the progress of the disease. Again the skin of the lower extremities and trunk may be alone affected, or the whole surface of the body may take part in the process. The part which first shows the thickening may also vary. Most often the skin of the buttocks or thighs appears to be earliest diseased, from there spreading upwards and downwards on the trunk and on the lower extremities. It may then become general over the whole surface of the body. On the other hand, the skin of the face may be the first point to show the induration, more particularly in the region of the cheeks.

As a consequence of the thickening and hardening of the skin and subcutaneous tissues, the affected parts become stiff and inflexible. If the face be involved, the mouth and cheeks are set as if moulded, mask-like, resembling the face of a doll, crying, sucking, swallowing being alike impossible. If the limbs be attacked the members are swollen, blue black to dirty brownish yellow in color, hard and rigid, extended or slightly flexed, but stiff and immovable. When the disease becomes general the infant lies motionless, with or without very feeble cry, as stiff as and still as death, with scarcely any respiratory movement and with an ever-weakening pulse. At this stage of the disease Trousseau and Parrot were able to lift the body by catching hold at either end, as one would raise a stick of wood, and it has been possible to balance the body on the radial surface of the hand placed under the back, just as one would balance a figure of marble or of metal.

Such, in short, are the characteristic symptoms of sclerema neonatorum. Variations in intensity and in extent of the induration occur, but correspond in general to the above description. In striking contrast, however, to this is the absence of general manifestations of disease of any of the vital organs. No heart or lung disease, no disease of the nervous system or gastrointestinal tract has ever been found that might be considered constant in or in any way causative of sclerema. There seems rather to be a universal prostration of all the vital functions. The malady runs its course slowly but fatally without giving the slightest clue in regard to the primary cause of the trouble. In the skin itself where the morbid process is mainly localized, there occur no microscopic changes that can be regarded as peculiar to or characteristic of the malady. Atelectasis of the lungs, congenital defects of the heart and morbid processes in the digestive tract have been described, but must be regarded rather as accidental complications than as having anything to do with causing the disease. Money described two cases complicated with paralysis, and concludes that the disease may be a trophic disturbance. Numerous hypotheses have been advanced to explain the peculiar clinical changes, but we must admit that from a practical standpoint we know little or nothing of their etiology, being able neither to retard nor to arrest its advance. Recovery rarely if ever occurs, the infant after illness of a few days to a week or more dying from the extreme prostration or asthenia.

Turning now from a general survey of sclerema, the history of a particular case may prove interesting.

J. K., full term infant of healthy parents, male, seven days old, at birth was quite cyanosed; extremities, ears, lips, face all were blue and livid, presenting the characteristic appearance of a "blue baby." Careful auscultation of cardiac area, however, discovered no audible murmur. Condition lasted forty-eight hours and gradually disappeared, leaving no trace. Baby nursed, bowels moved and urine voided in an apparently normal manner.

During night of seventh day baby cried almost incessantly and with no apparent cause, bowels moving and urine being evacuated as usual.

Examination.—The following morning the following facts were disclosed: The baby refused to nurse and seemed generally tender to the touch. Penis swollen and infiltrated with hard edema, so much so as to effectually close preputial opening. Skin of same was glossy, shiny and did not pit on pressure. Skin of scrotum was also swollen, hard and board-like, shiny and cold. Questioning revealed the fact that the little patient had not urinated since the night before. Percussion over hypogastrium revealed dulness and with a view to relieving the bladder a hasty circumcision was done and an unsuccessful attempt made to pass a catheter. Under a hot bath and warm fomentations, however, the bladder relieved itself, but nevertheless the hard, board-like infiltration continued and was rapidly spreading. The cord had not yet separated from the umbilicus, but there was no evidence of infection or inflammation in its neighborhood. Temperature per rectum 98.5 F.

On the following day the hard induration was still present and had spread upward on the trunk and downward on the legs. The least touch seemed very painful, causing the baby to cry for some time, whereas otherwise he was quiet. Bowels moved sluggishly and small in amount, greenish in color; urine also small in amount, stained diaper light yellow. It was impossible to obtain any for examination. Temperature 97. At this time a blood examination showed 6,000,000 erythrocytes per c.mm., with no deformity of same and no nucleated reds. Owing to difficulty in obtaining blood it was impossible to count white cells; but from study of ordinary smears they appeared to be less than normal in numbers and mostly of mononuclear type. Cultures taken from the blood were negative.

The next day the sclerema had spread over the whole of the extremities and midway up the trunk. Skin was hard and leathery, could not be pinched up into folds, was densely adherent to subjacent, all seeming to be fused indefinitely together.

The following day, the fourth of the illness, the conditions were much worse. The infiltrated areas were turned a deep bluish black, particularly the dependent parts, and were painful on least pressure. Bowels moved and urine voided, but very scanty in amount. Child refused to take any but slight amount of nourishment by a spoon. Legs were flexed at about an angle of forty-five degrees, were stiff and firm, impossible to straighten or bend. Sclerema had extended on chest, but arms and face were not involved. Temperature 96, rectum. Death the same afternoon.

Autopsy.—This was made the following day at 9 a. m., fourteen hours after death. It is important, especially on account of the negative results. The following changes were noted. Body slightly emaciated. Postmortem rigidity not well marked. Surface of body presents a mottled bluish-black to yellowish tint, the former color being most developed over dependent parts and on skin of extremities. Skin of legs, thighs, feet, scrotum, penis, pelvic regions, extending behind up to middle of back and in front midway to umbilicus, is swollen hard, board-like, stiff, glossy, not pitting on pressure. Skin can not be pinched up into folds by the fingers, neither will skin glide over subjacent tissues. The dark blue-black color is most developed in region of anus and penis, the circumcision wound of which appears gangrenous. Umbilical cord separated and stump is normal looking with no signs of inflammatory reaction about it.

On section, subcutaneous fat exceedingly small in amount. Skin of lower abdomen distinctly thickened, being three times the thickness of that of upper abdomen. On section it appeared very firm and fibrous, of mottled orange to lemon yellow to grayish color, subcutaneous fat showing a distinct reddish tinge. No serum exuded from cut surface. Heart and lungs normal with no sign of any congenital defect. Liver mahogany color, extending four cm. below free border of ribs with no macroscopic change. Gall bladder distended with thick tenacious black bile, which could not be squeezed into duodenum, although dissection of common duct disclosed no obstruction. Stomach distended with gas extending below to umbilicus and 1½ cm. to right of median line. Urinary tract normal; spleen normal. Mucous membrane of small and large intestine pink, soft and velvety with no signs of swollen follicles or of ulceration.

Such in short, were the results of the postmortem examination. Cultures were taken from the heart, spleen and peritoneum, but there occurred but a few colonies of *Staphylococcus albus* and variety of the color bacillus. That the presence of these organisms was accidental and not due to general infection I feel convinced, because of the lack of any symptoms pointing to an infective process such as fever, with enlarged spleen. Microscopic examination of tissues revealed no change. In the skin, however, corresponding to the marked clinical symptoms, we should expect marked pathologic peculiarities. No change, however, has been found at all commensurate with the macroscopic appearance. Northrup reported a typical case in which the microscope revealed nothing especially abnormal. Parrot found hardening and atrophy of the skin and rete malpighii, the cells appearing indistinct and forming a fused mass. The subcutaneous fat appeared atrophied and the interstitial fibrous connective tissues increased. The blood vessels were shrunken. In the present case the corium seemed thickened, the cells and fibers composing it having a homogeneous granular, hazy appearance, suggestive of cloudy swelling. The subcutaneous fat appeared normal, the interstitial fibrous tissue being little if at all increased.

Ballantyne found a "dried-out skin," some thickening of the layers with some diminution of the subcutaneous fat. The pathology and the etiology are very obscure. What relation these slight skin changes bear to the profound prostration of the disease is difficult to explain. Henoch examined the nervous system from two cases and found nothing abnormal.

From the date of its first description many and ingenious theories have been advanced to explain its occurrence. Underwood believed it was due to a spasm of the skin in consequence of breathing bad air. Leger thought it was due to an improper and incomplete development of the intestinal canal. Parrot taught that sclerema was not a disease, but only a symptom, an end-stage of a general condition of malnutrition, which he termed "arthrepsie," and that the thickening and drying up of the skin was due to the loss of fluids in consequence of diarrhea and to the absence of any reparative effort on the part of the other cells of the body. Langer, in 1881, advanced the theory that in consequence of the lowering of the body temperature, the palmitin and stearin, which form the principal part of the adipose tissue of infants, solidify, thus causing the thickening and hardness. This may be considered but a modification of the theory of Parrot that the reduction of temperature is consequent to the general condition of mal-nutrition and mal-assimilation, and following this heat loss solidification of the subcutaneous fat occurs. In other words, the skin changes depend purely on a chemical and physical change in the cutaneous fat, regardless of any vital activity on the part of the body cells. Were this true we might reasonably expect a like change to occur post-mortem in the case of infants. Ballantyne asserts that the skin changes are the result of the "drying out" of the skin incident to the diarrhea, and this view seems to be favored by Wiederhofer and Soltmann. This case, however, as well as that of Northrup and others, seems to prove that a preceding diarrhea is not essential to the development of the disease, nor a necessary symptom of its progress. Schmitt, in 1893, reported three cases in which he isolated micro-organism, mainly staphylococci, from the tissues, and he maintained that sclerema is due to a general infection with a definite micro-organism, but this observation has not as yet been corroborated by other observers. Pathologic evidence, on the other hand, shows no change at all comparable to the changes observed in general infection with any known organism. It may be, however, that the immature tissues of the new-born react to bacteria and their toxins differently than the mature tissue of adults with which we are more acquainted. It seems to the writer more plausible to regard the condition as the result of an autointoxication from improper functional activity of the gastrointestinal tract, the changes in the skin being secondary to the retention of the poison, and its direct action on the skin, incident to an attempt at elimination.

HYPERTROPHY OF THE SYNOVIAL FRINGES OF THE KNEE JOINT,

WITH A REPORT OF TWELVE CASES.

EDVILLE G. ABBOTT, M.D.
ORTHOPEDIC SURGEON TO THE MAINE GENERAL HOSPITAL.
PORTLAND, ME.

This disease has been described from time to time by various writers in medical journals, but as yet there has been only slight mention of the subject in works on surgery. The different authors have included this condition in their description of floating cartilage, internal derangement of the knee-joint and chronic synovitis, but have given little consideration to it independently. In designating the disease the profession have used various terms, such as rheumatic joint, torn cartilage, strained ligaments and synovitis; and undoubtedly some cases of it have been diagnosed as tuberculosis of the joint, which it sometimes resembles in its first stages and for which it might easily be mistaken.

From the cases which have come under my observation during the past year and a half I have selected twelve, typical in character, the treatment of which has extended over a sufficient length of time to allow definite conclusions to be drawn regarding them. Eight of these cases I operated on; the remaining four were treated by mechanical means. The unsatisfactory nature of the information contained in the text-books has led me to endeavor to formulate my own experience and its results.

ETIOLOGY.

The etiology is obscure. In a few of the cases traumatism plays an important part, while in others it has been impossible to associate injury with the beginning of the disease. In order to explain this condition in those cases where it is not traceable to injury, the complicated movements of the normal knee and the intricate distribution of the synovial membrane should be considered.

The knee-joint, like all diarthrodial joints, is lined with a synovial membrane, except where the articular cartilages are in contact. Here no membrane is found, except at the edge of the cartilage, which the membrane overlaps for two or three millimeters before merging into the cartilaginous structure. The inner surface presents a smooth shining appearance, interrupted (especially where the membrane folds to pass from one surface to another) by the synovial fringes, which are villous structures of varying size and length, somewhat resembling intestinal villi, the largest being perhaps one centimeter long. They are richly supplied with blood vessels, each villus containing a convoluted twig of an artery. Some of the fringes are, however, merely hernia-like protrusions into the joint of small masses of fat covered by membrane, which fill up unoccupied spaces.

The articulation between each condyle and the opposed almost flat surface of the tibia does not exactly form a hinge-joint, though strongly resembling one; and extension and flexion, the movements of which it is capable, are produced by a combination of gliding, rolling and rotation. In the movement of extension the condyles move parallel to one another, both gliding and rolling, until extension is nearly completed; and then the anterior part of the rolling surface of the external condyle having already come into full contact with the tibia, the femur is rotated inward on the tibia and the joint is fully extended. In the erect attitude the knee-joint, like the hip, is in a great measure maintained in the fully extended position without muscular effort; but there is some difference of opinion as to the manner in which this is effected.

Langer and Humphrey hold that the line of gravity of the body falls in front of the axis of movement of the knee-joint, and the tendency is thus to over-extension, which is resisted by all the ligaments of the articulation. If this view be correct, any strain produced, for instance, by overweight, long standing in one attitude or injury, would cause the knee to overextend, stretching the ligaments and allowing the joint, when moved, to deviate from its normal position. With this condition it is almost impossible for the fringes to escape being pinched, so complicated are the movements.

On the other hand, Meyer maintains that the line of gravity falls slightly behind the axis of movement, and that the stability of the joint depends mainly on the association of rotation with the beginning of flexion; for while the femur is prevented from rotating outward by the ileo-femoral ligament, which in its turn is kept tense by the weight of the body acting on the hip-joint, the tibia is fixed by its connection with the foot. Rotation between the femur and the tibia being thus impossible, flexion can not take place, and the joint is fixed.

If we accept the explanation of Meyer, which has the support of the majority, a weakened condition of the arch of the foot would have the same tendency to stretch the ligaments of the knee by preventing fixation of the tibia.

It seems to me that the latter condition would explain many cases, as a weak pronated foot is very closely associated with this disease; and while I have not found it in all cases, it has been present in many, and the use of a plate to support the arch has been of great service in remedying the trouble in the knee-joint. In those cases attributed to trauma it may result from a sudden wrench with the joint in an unfavorable position; or pressure of the joint against some hard surface daily may cause a thickening of the tissues just posterior to the patella tendon. This thickening pushes back the fringes into the joint between the surfaces of bone where they become pinched, and the joint motion causes a continuation of the pathological process.

PATHOLOGY.

Pathologically the disease consists in a nodular enlargement of the synovial fringes which project into the joint, with more or less thickening of the membrane. In the commencement of the disease only a slight increase of vascularity and a tendency to thickening of the fringes is noticeable. The membrane is slightly red around the base of the villi and the fluid which is occasionally present is insignificant in amount and ordinarily yellowish in color. This condition is followed by an increased hypertrophy of the synovial fringes, which varies from a slight and almost imperceptible hyperplasia to a condition where the fringes resemble a small bunch of half-grown grapes.

The synovial membrane begins to encroach on the cartilages. Normally it runs into the cartilaginous border for two or three millimeters, but now the hypertrophied membrane sends out processes which creep in still farther. The fluid increases in amount in a few cases, but in the majority it is absent. Microscopically the fringes show marked dilatation and branching of the vessels, and a large increase in the amount of connective tissue which is rich in cells. It is impossible to obtain growths in culture tubes, and no trace of bacteria can be found with the microscope.

SYMPTOMS.

The first symptom noticed by the patient is generally some difficulty in walking. Often on extending the leg he feels a slight pain, or he may be seized with sudden pain and fall on his knees. In some cases where the fringe is pinched the injury to the membrane is so extensive that an acute attack of synovitis occurs, and the patient is obliged to remain quiet some weeks. With rest the joint soon resumes its former condition with, however, a slight increase in the size of the fringes. In other cases the process is more gradual without any acute symptoms.

This condition continually grows worse, until there is partial or complete loss of function of the joint, and the patient is sometimes obliged to resort to crutches. In some cases inability to extend the leg appears, and the quadriceps extensor muscle atrophies. The patient complains of a sense of insecurity of the joint, and rarely a dull pain is present on motion.

Examination shows a slight bulging of the thickened membrane on either side of the patella tendon, generally more marked on the inner side. A little higher up the small portions of the membrane can easily be felt under the finger. The joint shows no redness or heat, except in acute attacks, and on motion there is absence of grating. Measurements seldom show much enlargement, and movement can be carried beyond the usual limit. The ligaments are lax, and some lateral motion is present.

TREATMENT.

The treatment of these cases is mechanical and operative. And early diagnosis is very important, as it is at this time that much can be accomplished by conservative methods. As the disease is probably due to a small portion of the fringe being caught between the surfaces of bone, resulting undoubtedly in most cases from a strain of the ligaments, which allow of too free motion of the joint, attention should first be given to ascertaining the cause.

Mechanical Treatment.—The mechanical treatment, therefore, consists first in correcting any condition that may exist which tends to strain the muscles and ligaments of the joint. In my hands the use of hot air applied at least every other day has seemed to be very beneficial. Strapping with adhesive plaster has also been of assistance, not only because of the pressure which it exerts on the membrane, but also because it limits the joint motion.

In those cases where flatfoot is present a plate will aid much in bringing the joint surfaces into a normal position, and by fixing the foot the knee is made more stable. A brace which limits movement will be found useful in cases where the ligaments are lax, as it lessens lateral motion and prevents the leg from hyper-extending. Keeping the joint at rest for a long period by encasing the limb in some fixed dressing, such as plaster of paris, has proved worthless in my experience, as it is impossible to exert any appreciable influence on the hypertrophied fringes by simply fixing the joint.

Operative Treatment.—Many of these cases have progressed to such an extent that conservative treatment

Recovery was uninterrupted, and the patient returned to his home February 19, motion being nearly normal. A plate was made for the left foot and apparently was a great help in the after-treatment. A subsequent examination shows no tendency in the disease to return, and the gait is normal.

Case 6.—W. A., man, aged 29, engineer by occupation. The patient had been well until two and a half years before. While stepping from a cab one night he was seized with a sudden pain in the right knee. The following morning the joint was swollen and painful, but with rest these symptoms subsided in a few days. Some months after this he noticed when walking that the leg suddenly flexed and, in placing the foot, he was obliged to use care to avoid falling.

He was seen by me for the first time March 26, 1901, and examination showed a very lax joint, with small masses around the patella. The right foot was flat, with marked tenderness under the heel. There was so little thickening around the knee joint that an operation was not advised Hot air treatment, combined with adhesive strapping, was begun, an arch was placed under the foot, and an immediate improvement was noticed. At the end of three months it was impossible to detect any thickening around the knee, and the joint was apparently in a normal condition.

Case 7.—E. B., woman, aged 34. First seen by me April 17, and gave the following history:

For the previous year she had experienced some discomfort in the right knee on getting up from the floor. This condition gradually grew worse, until there was considerable difficulty in walking and climbing stairs. Extension of the leg caused a darting pain at times, and there was a sense of insecurity about the joint.

Some two weeks previous to this the patient, after a long drive, found the knee so painful and swollen that she was unable to use it, and was obliged to have assistance to alight from her carriage. The family physician was called, and found some swelling and redness. Hot packs were used, followed by strapping, and she was not allowed to walk. Examination showed a small amount of fluid and marked hypertrophy of the synovial fringes. The arches of both feet were flattened with some tenderness.

As the patient was going out of town for the summer, continued strapping with adhesive plaster and plates for the broken arches was advised. She returned in the fall, and in consultation with the family physician I advised an operation. This suggestion, however, was not adopted, and the hot-air treatment and strapping commenced. Treatment was continued for some ten months with improvement, and at the present time the joint is in a very good condition and gives no trouble whatever.

Case 8—R. W., woman, 37 years of age; first seen by me June 5, 1901. For the previous four years her left knee had been swollen and painful at times. Had often fallen when stepping from her carriage, and during the past year had not been able to raise the foot from the floor when sitting; had been obliged, when walking, to swing the whole limb to prevent the leg from flexing. Examination showed slight effusion with marked hypertrophy of the synovial fringes. The patient was unable to extend the leg by muscular effort, and there was much atrophy of the thigh. The arch of the foot in this case was also flattened.

Operation was advised, as any other form of treatment seemed hopeless. A large quantity of tissue was removed from the joint, after which it was irrigated and placed in plaster. In two weeks' time motion was commenced. The patient made a good recovery, and in three months' time was able to extend the leg at will. There has been no return of symptoms, and the patient walks as well as formerly.

Case 9.—E. J., woman, 23 years of age. First seen by me Aug. 13, 1901. About two years before patient noticed some difficulty in left knee when playing tennis. Sudden movements were painful, and at times fixation of the joint was impossible. This condition grew gradually worse, and the patient repeatedly fell when walking. A knee-cap was worn for a while, but gave only temporary relief. Examination showed very lax ligaments, and motion in all directions was more than normal. The joint was somewhat enlarged, and small masses could be felt all over the anterior surface of the knee.

An operation was advised, but was delayed until the following November. Extensive disease of the fringes was found and a considerable quantity removed. The leg was placed in plaster for two weeks, after which motion was commenced.

The case did well until the fourth week, when sciatica of a violent type complicated matters, and I was obliged to place the leg at rest for some time. Firm adhesions formed, which were subsequently broken. This was followed by a renewal of the sciatica, and I was again obliged to put the leg at rest. Since that time the leg has been worked gently, and motion to a right angle obtained. The joint continues to improve, and undoubtedly full flexion will eventually be attained.

Case 10.—M. F., man, aged 26. First seen by me Oct. 16, 1901, at the Maine General Hospital in consultation with Dr. Brock. In December, 1900, patient fell from a horse, injuring his knee. This was followed by swelling and pain, which lasted some weeks. After recovery from the fall he was able to walk, but the joint remained weak, and was very unstable. Some months later this condition became aggravated and the leg would flex on the thigh when the patient was walking, causing him to fall He was finally obliged to use crutches.

Examination showed a small effusion into the joint, and small bodies could be felt there. The synovial membrane was thickened around the patella, and the ligaments were very lax, allowing much lateral motion. An operation was advised, and was performed the following day. All the fringes were removed and the limb placed in a fixed dressing.

Motion was not commenced until November 16, when ether was given and the adhesions broken. The patient made a good recovery, and was discharged November 26. At the present time he has good use of the joint and is apparently well.

Case 11.—H. W., a woman, 26 years of age; seen for the first time Nov. 24, 1901. About four years previous to this time the patient noticed slight soreness around the left knee after walking. The difficulty was so slight that it received no particular attention until the following year, when she consulted a physician, who advised anti-rheumatics and a knee-cap, from which she seemed to get some relief.

About two years ago she had a fall, striking on the knee. This was followed by an acute attack of synovitis, from which she soon recovered. Since then the patient has had repeated attacks of acute inflammation. Examination showed some thickening around the patella, with very little fluid in the joint. The ligaments were very lax, allowing considerable lateral motion

As pain had been quite a prominent symptom, an *x*-ray picture was made, which showed the bones to be in a normal condition. The family history was negative. An operation was advised. The fringes were found to be much enlarged, and a considerable amount of membrane was removed. The joint was irrigated, and a small elliptical piece of the ligament was removed on each side of the patella.

The patient made a good recovery. Motion was begun at the end of the second week, and complete flexion was attained at the end of two months. At the present time there is no difficulty in walking, and she can use the knee with as much ease as the other.

Case 12.—J. M., man, 33 years of age. First seen by me Dec. 12, 1901. Family history good. About two years previous to this time he noticed a tender spot under the right heel, which caused considerable pain to him when walking. A short time after this the right knee suddenly gave way under him while walking, and he was confined to his bed for two weeks with acute synovitis. There was a repetition of attacks until his condition became so serious that he was obliged to use crutches.

Examination showed marked thickening around the joint, with numerous masses which slipped from under the finger.

There was inability to extend the leg, and much atrophy of the thigh The arch of the right foot was flattened and painful.

An operation was advised and was performed the following week. The fringes were found much enlarged, and a considerable amount was removed. There was a good deal of swelling following the operation, but this rapidly subsided. Recovery was good, the patient is now able to walk without aid, and motion is normal.

CONCLUSIONS.

From my observations it seems to me that such cases should be considered independently, and not included among the other diseases of the knee-joint. A thorough microscopic examination of the tissue which was removed shows it to be a simple inflammatory tissue, and not due to any micro-organism. While the etiology is obscure, it evidently is due to some fault in the weight-bearing structures of the lower extremity, which causes the ligaments of the joint to become lax.

In all the cases which I have examined since the matter was brought to my notice a flattened arch has preceded the knee-joint trouble, and the use of a plate has been of great service in treating the disease. The matter of diagnosis is not difficult, although a torn cartilage somewhat resembles this condition. Examination of the cartilages was made in all the cases where operations were performed, and in all they were found intact.

It has been impossible to account for the paralysis of the quadriceps extensor muscle, which I found in three instances; but in several of the cases operated on, where it did not exist before the operation, I have found a similar condition afterwards, which was the last symptom to disappear. This shows that sometimes this condition does occur when there is very little to cause it. The question whether a case should be treated by mechanical methods, or whether it should be operated on, is a matter which must be left to the judgment of the surgeon; as some cases which seem doubtful yield easily, while others which are apparently slight will not improve until the fringes are removed.

THE USE OF A MYDRIATIC AFTER THE AGE OF FORTY-FIVE.

HORACE M. STARKEY, M.D.
CHICAGO.

(Concluded from p. 1078.)

THE THEORY AND PRACTICE OF PROMINENT OPHTHALMOLOGISTS.

In the letters sent out the following questions were asked:

1. What is your practice in regard to the use of mydriatics or cycloplegics in refraction work in patients beyond 45 years?

2. If they are used frequently, what advantages and what disadvantages or dangers, if any, do you find in such use?

3. If they are used infrequently or not at all is their omission due to disbelief in their utility or to fear of bad effect?

4. Is the belief in these advantages and disadvantages theoretical or the result of your own experience?

5. Can you cite cases in your own practice in which glaucoma has seemed to be caused or aggravated by the use of these drugs?

Ninety of the 100 to whom letters were sent replied. These replies are classified as well as may be according to the answers to the first question. Three classes are made: First, those who do not use them at all; second, those who use them rarely, and third, those who use them frequently. From the answers received a strict classification under these heads is impossible, for it is doubtful if a few of those put down as never using them do not on rare occasions employ them, and some of those noted as rarely using them may actually use them oftener than some of those who are noted as frequent users.

Classified in this way it is found that of the 90 replying 22 never use cycloplegics or mydriatics for refraction work after the age of 45, 32 use them rarely and 36 use them frequently. Of the first, 2 have used them repeatedly for experiment and have discontinued such use because they find they secure equally good results without them. Of the latter, 17 use them in a majority of cases at first examination. Where it is possible the ideas expressed by the answers are incorporated in the table of replies, but in some cases longer extracts are given below.

There is a very commonly expressed fear of glaucoma resulting from the use of these agents, but 25 state that they have no fear of producing increased tension in any case where there is not already the commencement of the glaucomatous process. Thirty-four have seen glaucoma caused or aggravated in their own practice and 11 have seen such cases in the practice of others, while 41 have seen no such cases. Thirty-six cases of glaucoma either produced or aggravated are mentioned. Some of these are reported most thoroughly and carefully. (The author regrets that the length of this paper will not permit them to be incorporated in full just as reported.)

QUOTATIONS FROM REPLIES RECEIVED.

9. W. R. FRINGER: I should use a cycloplegic in a patient over 45 if I thought it indicated in that particular case, providing there was no indication that the patient was predisposed to glaucoma.

11. H. GRADLE: I know of no justification for the use of a cycloplegic for the determination of refraction after the fortieth year of life, and consider it improper. Whenever I use a mydriatic to permit ophthalmoscopic examination of elderly people on account of narrow pupil I usually follow it by eserin until the pupil is normal, except when the eye is distinctly a soft one.

12. E. E. HOLT: It seems to me that oculists should advocate the use of mydriatics for the treatment of the eyes, to give rest, quiet spasms and reduce inflammation, not for refraction work, for the state of refraction can be obtained without mydriatics.

By mistake of a nurse I once had a solution of scopolamin (1/5 per cent.) put into the eyes of a person suffering from a subacute attack of glaucoma, but it seemed to do no harm, and the patient made a good recovery. In cases of a mixed character, when iritis and glaucoma exist together, I have sometimes thought that mydriatics made the eye worse, but I do not recall a case of glaucoma as due to the use of mydriatics alone.

16. J. M. RAY: I have time and again used the drops and have found that I can measure the refraction and give my patients satisfaction without putting them to the inconvenience and annoyance that drops entail. In fact, I find that the more experience I have in refraction work the less inclined I am to use a mydriatic; rarely do I find it necessary in a patient over 40. Careful testing, ophthalmometric measurements, shadow test and ophthalmoscope, followed by a second examination with trial lenses, have proven in my experience all that is necessary except in young people.

21. CASEY WOOD: I do not use cycloplegics for determining the refraction in persons over 45 years of age, because I have repeatedly found exactly the same results with the methods I employ (ophthalmometer, skiascopy with euphthalmin and cocain and test lenses) as with the strongest cycloplegics.

TABLE OF ANSWERS.

	First Question.	Second Question.	Third Question.	Fourth Question.	Fifth Question.
1. A. N. Alling.	"Almost without exception they are *unwarranted* and *unnecessary*."	....	"Principally former."	....	"No, because I am careful."
2. W. C. Bane.	Not used.	....	"Not used because I have not felt the need."	....	"None when used in refraction work."
3. Chas. H. Beard.	"I omit them absolutely."	....	"To both."	"The result of my experience."	A case of hemorrhagic glaucoma.
4. D. C. Bryant.	"Do not use any mydriatics in patients beyond 45."	....	"Consider them useless except in the rarest of rare cases."	"Result of experience."	"Yes; have seen several cases greatly aggravated. Atropin not used by me."
5. W. L. Dayton.	Never cycloplegic, sometimes mydriatic.	Have not feared bad results.	Both.	Theory only.	Had cases where atropin used for disease increased tension.
6. A. J. Erwin.	Not used after age of 30.	No danger.	"Not used with adults because useless, there being no latent condition that will bear correction."	Observation.	None in my own practice; several cases caused by others.
7. Geo. F. Fiske.	"Seldom use them."	....	"Disbelief in their necessity."	Both.	No.
8. Harry Friedenwald.	"Rarely, if ever."	....	"To both." Risk greater than advantage.	....	Caused, no.
9. W. R. Fringer.	"Never used."	....	"Not thought them indicated."	Theoretical.	No.
10. E. J. Gardiner.	Very seldom; do not recall single case.	"Think them superfluous."	Both.	Theoretical.	No.
11. H. Gradle.	"I know of no justification for the use of a cycloplegic."	....	"A skilful observer does not require them."	....	No.
12. E. E. Holt.	"Never use them for refraction work."	....	Had one case of paralysis of acc. following 1 per cent. atropin solution.	Theoretical.	No. In one case of glaucoma atropin used by mistake without bad effect.
13. Lucien Howe.	"Not ordinarily."	....	"Fear of bad effects."	Both.	Apparently one instance.
14. L. J. Leutenbach.	"Do not use them."	....	"Mainly the latter."	Experience.	Four cases observed.
15. W. T. Montgomery.	Cycloplegic not used in ten years.	....	Both.	Experience.	Several of both.
16. J. M. Ray.	Never use them.	....	Disbelief in utility, not fear of bad effects.	Experience.	
17. Dunbar Roy.	Never found them necessary after 45.	....	....	Experience.	No.
18. Miles Standish.	"As a rule, I do not use them."	....	"Fear of harm."	"Experience."	"I can."
19. K. K. Whelock.	Not used. Prefer to change lenses several times if necessary.	....	Both.	Both.	Have known of two cases after use of cocain.
20. Chas. H. Williams.	"I do not use them."	....	"Disbelief in their utility."	"Experience."	"No."
21. Casey A. Wood.	Mydriatics often. Cycloplegics rarely or never.	....	Disbelief in their utility only.	Experience and experiments.	Several cases where glaucoma was aggravated and others where it followed use of atropin.
22. H. V. Würdemann.	No cycloplegics; occasionally mydriatics.	....	Both; unnecessary and dangerous.	Experience.	Yes; both. (One case reported in detail.)

Twenty-two do not use cycloplegics in refraction work after the age of 45.

	First Question.	Second Question.	Third Question.	Fourth Question.	Fifth Question.
23. Frank Allport.	"Never use unless imperative."	....	Fear bad results.	Theoretical.	No.
24. S. C. Ayres.	Occasionally.	Not required frequently. Used very cautiously.	....	Experience.	Not in refraction work. In some other cases.
25. A. Barkan.	Rarely.	....	Rarely required.	Experience.	No.
26. A. E. Bulson, Jr.	"I rarely use them."	....	Both. Fear glaucoma.	"Partly both."	One case.
27. Swan M. Burnett.	"Only in exceptional cases."	....	Disbelief in utility.	Both.	Only in one or two operative cases.
28. Fleming Carrow.	Only in strong presumption of astigmatism.	....	"Not to fear of bad effects."	Experience.	One undoubted case.
29. J. W. Chamberlin.	"Seldom use them."	....	"Do not believe in the general necessity."	Both.	"I can not."
30. Wm. Cheatham.	"*Very* rarely."	....	Both.	"Mainly theoretical."	"Several in younger persons."
31. J. E. Colburn.	I use them in low astigmatism.	Greater accuracy.	Disbelief in general utility.	Experience.	No.
32. Leartus Connor.	Rarely used.	....	Disbelief in utility.	Experience.	No.
33. E. C. Ellett.	Occasionally essential in oblique as.	....	Both.	Disadvantages theoretical. Advantages experience.	No.
34. Albert B. Hale.	Rarely (?).	....	Fear of bad effects.	Theoretical.	One case of chronic glaucoma had pain increased.
35. George N. Harlan.	"Homatropin occasionally."	....	"Both."	"Both."	One case.
36. F. C. Hotz.	"Very rarely."	....	"Regular use is not of advantage."	"Found useful in few cases."	No.
37. A. E. Kegley.	Rarely.	....	"Both."	"Experience."	Four cases after use of atropin.
38. Herman Knapp.	Rarely use cycloplegics; mydriatics frequently.	....	Both.	Experience.	Yes; both.
39. Chas. W. Kollock.	"I rarely use them, but do not hesitate when they are indicated."	....	Both.	Experience.	No.
40. J. A. Lippincott.	"Quite infrequently."	....	Both.	Experience.	Yes; several cases of increased tension.
41. J. O. McReynolds.	Cycloplegia seldom. Mydriasis frequently.	....	The former.	Experience.	Increased tension in many cases.

Thirty-two use cycloplegics *rarely* in refraction work after the age of 45.

	First Question.	Second and Third Questions.	Fourth Question.	Fifth Question.
55. A. R. Baker.	Cautiously. More frequently than formerly.	2. Of great value in refraction. 3. Fear of bad effects.	Largely theoretical.	No cases of my own; several others.
56. J. P. Davidson.	Frequently.	2. Advantages, proper correction of refractive error. Disadvantages, none.	Experience.	Several cases, not in marked degree.
57. Edw'd J. Bernstein.	Frequently to uncover ametropia.	2. Advantages same as in young. 3. No fear of bad effects.	Experience.	No.
58. Randolph Brunson.	One or other in about 75 per cent. cases.	2. Uncovers masked H. and H. As. 3. Experience taught me production of glaucoma purely a myth.	...	No.
59. J. Edgar Dean.	About 30 per cent. after 45, instead of 70 per cent. as before.	2. Advantage, greater accuracy. 3. Not so frequently necessary as age advances.	Experience.	No. Perhaps 8 or 10 cases in others.
60. H. Bert Ellis.	If lens tests show discrepancies.	2. Probably cycloplegic in 50 per cent. of cases with no bad results.	Experience.	No. Have not used in glaucoma.
61. C. R. Elwood.	If objective and subjective tests disagree.	2. No disadvantage. Better results in H. and H. As.	Both.	One case.
62. Harold Gifford.	Answer indefinite.	2. Advantages. It gives a fixed point to start from.	...	One case.
63. George M. Gould.	Just as necessary as earlier.	2. No danger in healthy people and healthy eyes. Advantages same as in the young.	Experience.	No.
64. H. F. Hansell.	When there appears to be latent H. or H. As.	2. No danger. 3. Necessity seldom.	Experience.	No.
65. Clark W. Hawley.	Whenever thought necessary.	2. Have uncovered errors that were uncertain before.	Experience.	No. Have seen one case.
66. J. F. Herbert.	No age limit.	...	Experience.	Aggravated in a single case.
67. Alvin A. Hubbell.	Many cases up to 50 years old.	2. No danger except in incipient glaucoma. Advantages same as in the young.	Experience.	No.
68. Edward Jackson.	Cycloplegic in a minority of cases.	2. Same as in younger patients. No danger if glaucoma excluded.	Experience.	But one case.
69. George F. Keiper.	"Always use homatropin (1 per cent. sol.)."	2. Advantage a widely dilated pupil, no danger if followed by eserin.	Experience.	No.
70. H. C. May.	Homatropin and cocain in about 10 per cent. of cases.	2. More accurate correction of As. and H. especially in the nervous.	Experience.	No.
71. Ellis Phillips.	In nearly all cases under 50 years.	2. Can do much more reliable work. Almost no disadvantages.	Experience.	One case.
72. Wm. C. Posey.	Invariably use homatropin when As. suspected.	2. More accurate correction. 3. No bad effect.	Experience.	No.
73. Walter L. Pyle.	In all new patients with active accommodation.	2. Advantages suspension of accommodation; no danger from age.	Experience.	No.
74. R. L. Randolph.	Generally use cycloplegics beyond 45; not influenced by age.	2. Have found no dangers. Omitted when two consecutive examinations agree.	Experience.	No.
75. Wendell Reber.	Used as readily between 45 and 50 as before.	2. Advantage both total amount and axis of As. are more certain.	Experience.	Personal knowledge of but one case.
76. H. O. Reik.	Homatropin used with majority.	2. Great service in securing accurate results; no bad effects.	Experience.	No.
77. Dudley S. Reynolds.	Homatropin used when V. is below 6/VI and in astigmatism.	2. Have seen no bad effects from homatropin.	Experience.	Homatropin, no. Atropin, yes.
78. G. Oram Ring.	Very frequently.	2. Necessary in certain cases.	Experience.	One case (accidental).
79. S. D. Risley.	Frequently.	2. Necessary for accurate work.	Extended experience.	No; many cases in others' practice.
80. S. O. Richey.	Frequently.	2. Necessary for accurate work.	Experience.	No.
81. G. C. Savage.	Frequently.	2. No danger in proper cases.	Experience.	No.
82. Wm. M. Sweet.	All cases where spasm of acc. suspected.	3. No fear in proper cases.	Experience.	No.
83. J. L. Thompson.	Always at first examination.	2. Necessary.	Careful observation in at least 20,000 cases.	One case.
84. C. A. Vesey.	Always in As. and H.	2. Necessary for accurate correction.	Experience.	No.
85. J. E. Weeks.	Used in first examinations.	2. Required for careful examination.	Experience.	Cocain seemed to excite attack in one case.
86. Cassius D. Westcott.	Cycloplegia at all ages.	2. More accurate refraction. 3. Exclude glaucoma.	Experience.	No.
87. W. H. Wilder.	No hesitation in asthenopia and astigmatism.	2. In ophthalmoscopic examination and relief of spasm.	Both.	One case, quickly relieved by eserin.
88. H. B. Young.	May be 5 per cent. of cases. Either homatropin or scopolamin.	2. Same advantages as in younger people.	Both. I use caution.	Not in refraction work. One case after extraction. Relieved in 12 hours by eserin.
89. C. F. Clark.	Acc. often active and cycloplegic used without hesitation.	2. Same advantages as in younger patients. No disadvantages if glaucoma excluded.	Experience.	Glaucoma excited in a few not refractive cases.
90. W. T. Southard.	Homatropin frequently; atropin never.	2. Necessary to correct examination. No disadvantages if used carefully.	Experience.	No. I carefully exclude glaucoma.

Thirty-six use cycloplegics frequently in refraction work after the age of 45.

22. **H. V. Würdemann:** Both unnecessary, as the accommodation powers are weak and latent, hyperopia has become manifest and fear of bad effects.

24. **S. C. Ayres:** I occasionally use cycloplegics in persons beyond 45 years of age. I do not hesitate to use them when the asthenopic symptoms are distressing and where former glasses have not been satisfactory.

27. **Swan M. Burnett:** I do not use them at that age, because the accommodation has ceased to be a disturbing factor, and a wide pupil brings disadvantages of its own.

32. **Leartus Connor:** I used mydriatics in my early practice frequently until convinced that no good came from them, as a rule. In some cases in which hardening of the lens had been long delayed mydriatics had the same value as at a much earlier age. However, my practice is based on my experience.

33. **E. C. Ellett:** In cases with asthenopia and small errors, .50D. or less with astigmatism, especially oblique astigmatisms, I find most help from mydriatics in people over 45. I fear a bad result (i. e., glaucoma); hence I make unusual effort, by repeated tests, to avoid using them. Their utility is unquestionable, but still they are rarely absolutely necessary in these cases.

34. **A. B. Hale:** I use euphthalmin very often at all ages. Scopolamin I also use when I can not get good refractive results, atropin only when the iris is suspected of inflammatory involvement.

37. **A. E. Kegley:** I rarely use them, giving the patient the full manifest correction, and at this age with their assistance, the latent trouble with accommodation soon shows, and then I continue to change lenses until the patient is comfortable.

41. **Jno. McReynolds:** If a diseased condition indicates a cycloplegic I use it at any age, and after the extraction of glaucomatous cataracts I have used atropia very frequently with the result of good reading vision, and the same is true in some cases of iridectomy for glaucoma in which an iritis called for rest of the iris and ciliary body.

44. **C. A. Oliver:** Advantages very rare. In a few cases of pathologic spastic condition of the ciliary muscle, which later have given way to paresis, either normal from senile changes or abnormal from degenerative processes. No disadvantages, as I make it an unalterable rule to thoroughly study every case of ophthalmic disease presented to me.

54. **Hiram Woods:** Occasionally I find it necessary to make H. or H. A.'s (diagnosed objectively) "manifest." Such cases usually have P. over-corrected by examining optician and static error unnoticed. I do not hesitate to use a cycloplegic if indications are present which would make me use it on a young person.

57. **Edward J. Bernstein:** I frequently find uncorrected ametropia or badly corrected ametropia, just as one finds them in younger persons. Often with this added, that they are borne with resignation as a part of the inevitable while younger persons would complain. Then, of course, with a dilated pupil more peripherally placed lesions are often brought out.

59. **Edgar Dean:** I certainly do not draw the line at 45 years at all, nor even make an inflexible line at 60 years, for my records show their use at 62, 63, and in one case at 70 years.

66. **J. F. Herbert:** Personally, I think the age limit for the use of mydriatics and cycloplegics is a "bug-a-boo," a "myth." I never hestitate after I have made an ophthalmoscopic examination and find no contraindication, to use either up to any period of life. When I find a patient at 50 years or over with active accommodation I always use a cycloplegic.

67. **A. A. Hubbell:** I have used cycloplegics (mostly) homatropin) for 22 years in a large practice, and I have never induced or aggravated a case of glaucoma by them. I have even used homatropin in known incipient glaucoma without aggravating it. In these cases I usually supplement with a myotic.

70. **C. H. May:** I am careful to test the tension and to examine the fundus before using the cycloplegic (hom. and co. combined). I have never seen a case of glaucoma result from such instillations, either in my own practice or in that of others.

72. **Wm. C. Posey:** I have used homatropin in this way in thousands of cases and have never had a bad effect following the use of the drug. I have never seen glaucomatous symptoms provoked by it. Of course, I always take the precaution of making careful ophthalmoscopic examination of cases prior to the instillation of any drug and where there is glaucomatous excavation or the suspicion of one, a mydriatic is never used.

75. **Wendell Reber:** If there is any low-grade cylindric error the ciliary muscle is making the fight of its life between 45 and 50, especially in sound, healthy subjects, and non-mydriatic prescriptions must be based on frequently repeated examinations or the surgeon will be often led into error. Even with repeated measurements it is often impossible to assure one's self exactly what the refractive status is. If there is high-grade astigmatism the patient will in all probability have been carefully refracted under cycloplegia before presbyopia sets in and the ciliary muscles have been taught correct habits. It is in the presence of astigmatism of 0.75D. or less that the ciliary muscle can lead the most painstaking examiner astray when measuring incipient presbyopes, and particularly is this the case in moderate exophoria. Therefore, unless the previous ophthalmoscopic study contrainterdicts cycloplegia, I never hesitate to use homatropin with cocain any time between 45 and 50, or scopolamin with cocain in the proportion of 1/5 of a grain of the former to the ounce of water. Any latent glaucomic tendency that may be lit up by these weak solutions is easily controlled; and what is of more consequence, it will bring to early notice and treatment occasional cases of glaucoma that would otherwise progress to a much more dangerous degree before being recognized, as pointed out by Jackson three or four years ago.

77. **Dudley S. Reynolds:** Cycloplegics are frequently necessary in persons above 50 years of age. Considerable accommodation exists in the eyes of robust astigmatics of 60.

79. **S. D. Risley:** I have never seen a case of glaucoma in my own hands caused by mydriatics. I have seen cases of glaucoma following a mydriatic, but a careful study has in every case justified the belief that the eye was on the verge of an attack before its use, and that the mydriatic should not have been used primarily. I believe that the mydriatics should not be used in suspicious eyes at any age.

80. **S. O. Richey:** The practice is to wholly correct the static refraction in those above as well as those below 45 years of age.

83. **J. L. Thompson:** Many persons over 45 years of age have considerable power of accommodation, I therefore always use cycloplegics in my first examinations. Indeed, this is my practice until after their 50th year: scopolamin, when under 46; homatropin, if over that age.

84. **C. A. Vesey:** The advantages are that a latent astigmatism may thus be worked out so that a proper correction of the refractive error may be given, thus making the patient far more comfortable than if no correction of the astigmatism was made. In cases of high hypermetropia in which the amount of hypermetropia does not manifest itself by the ordinary use of the test lenses, the degree of hypermetropia may be ascertained, the difference in amount between the two eyes noted, so that we have a much better knowledge of the optical conditions of the eye to form a basis for the more intelligent prescription of glasses. Thus Mrs. L., aged 48, had been using +S.2.50 D. in each eye for several years, giving a vision of 6/6—. No other glasses were employed. Additional spherical or cylindrical lenses blurred the vision. Refraction under homatropin gave the following result: O. D.+S.5.00 D.⌣1.00 D.C.ax.95 deg.V.=6/5; O.S.+S.5.50 D.⌣+1.00 D.C.ax.85 deg.V.=6/5. A reduction of +S.50 D was made in each eye, and the patient has been wearing the glasses with perfect comfort. In this case a large amount of latent hypermetropia, as well as the astigmatic error, did not become manifest until after the use of homatropin.

87. **W. H. Wilder:** There is the great advantage that the refractive media and the fundus can be carefully examined.

Retinoscopy can be practiced more satisfactorily. I have found some patients over 45 years of age who could partially conceal astigmatism, because of spasm, who were relieved by the correction of the defect. This is particularly noticeable in nervous individuals.

QUOTATIONS CONCERNING GLAUCOMA.

3. C. H. Beard: A case of hemorrhagic glaucoma once occurred in my practice which I greatly fear was due to the use of atropin. I consider the indiscriminate employment of mydriatics in elderly persons, especially with those of degenerate vascular systems, as most pernicious. In the fitting of glasses, I rarely prescribe a cycloplegic for an individual past 35.

19. K. K. Wheelock: Have known glaucoma to be precipitated in two cases by the mydriatic effect of cocain. Have had two cases and in others such diminution of vision, temporarily, as led me to think disturbances in intraocular circulation must be the cause.

21. Casey Wood: I have seen two or three cases in which glaucoma followed the use of both cycloplegics and mydriatics, but as the ordinary forms of this disease show themselves in attacks I see no reason why these remedies should be blamed for a disease that would appear in any event. What proof have I, in the cases referred to, that the glaucomatous attacks would not have appeared in any event? Mydriatics and cycloplegics, say a million times a year, are employed in the United States; would it not be remarkable if glaucoma—a comparatively common affection—did not occasionally arise after their employment? If one were to accept this *post hoc propter hoc* reasoning, one could equally show that glaucoma is brought on by taking Epsom salts or riding on the elevated trains. That both classes of drugs raise the tension perceptibly in about 10 per cent. of all cases of eye diseases where there is congestion of the uveal tract (and in some normal eyes), and that the proportion is greater (to an extent unknown to me) in persons over 45 years of age than in those under 25, is, in my experience, true, and that in persons prone to attacks of glaucoma mydriatics very occasionally precipitate an impending attack, I believe, but this disadvantage can usually be eliminated by noting the history of the case and in making the usual preliminary examination of the eye before using the cycloplegic or mydriatic.

22. H. V. Würdemann: Cases of so-called simple glaucoma where, for diagnostic purposes, I have used atropin to develop further intraocular tension. Marked cases in which atropin has been used by unskilled practitioners where acute inflammatory glaucoma has ensued on use of atropin instillation for purposes of measuring the refraction.

26. A. E. Bulson: I think I was instrumental in producing glaucoma in a previously sound eye and normal tension by the use of atropin. Since then I have used atropin in patients over 40 to 45 with extreme caution.

28. Fleming Carrow: I have the records of one positive and undoubted case of glaucoma, being produced by the continued use (one month) of atropia sulphate for purposes of refraction.

30. Wm. Cheatham: I can not cite a case of a person that age or over. I have seen it in younger patients several times. I saw it in one case in which atropia was given internally in a large dose in a woman 55 years old.

34. Albert B. Hale: One case, a woman of 60, suffering from chronic glaucoma, had the pain temporarily increased by euphthalmin.

35. George N. Harlan: Have seen an attack of violent glaucoma directly induced by instillation of atropia and retinal pulse induced by use of homatropin.

37. A. E. Kegley: I have had four cases where glaucoma followed the use of atropin in patients above 45 years old. Three speedily recovered, and one still has chronic glaucoma in a light form.

38. H. Knapp: Both, in three cases even by euphthalmin; in all cases the attack was, however, promptly cut short by instillation of 1 per cent. solution of eserin.

45. Casper Fischel: I remember distinctly three cases in which simple glaucoma was detected by the use of homatropin and cocain.

46. A. E. Prince: I have had three cases where I recognized a mydriatic as the exciting cause of glaucoma.

48. Geo. E. de Schweinitz: A woman past fifty, with chronic nervous disease, probably some irregular form of ataxia; one drop of a 1 per cent. solution of atropin instilled for ophthalmoscopic purposes by the resident physician; sharp glaucomatous attack followed a few hours later, controlled with eserin. 2. A Jewish woman, aged 36, homatropin instilled for the purpose of determining refractive error by a colleague; typical acute glaucoma a few hours later; treatment eserin, salicylate of sodium and paracentesis cornea, the patient refusing to permit iridectomy. Three weeks later I saw the patient, typical glaucoma resembling the chronic congestive type; patient declined operation. Subsequent history unknown. 3. Acute glaucoma in a woman aged 35, brought on by the instillation of a mydriatic, whether atropin or some other mydriatic unknown, for the relief of an acute inflammation of the eye occurring during grippe; patient seen one week later with typical acute glaucoma, promptly relieved by iridectomy. There is some doubt whether the primary inflammation was an attack of glaucoma aggravated by atropin, or whether it was an ordinary conjunctivitis, and the attack of glaucoma induced by the instillation of atropin. I did not see the patient until a week after the increased intraocular tension began. Both cases evidently were predisposed to glaucoma, and this I believe to be the history of all cases of glaucoma which are produced under the influence of mydriatics. I have a number of times seen what seemed to me to be temporary rise of tension after the instillation of mydriatics in elderly people, but never enough to amount to a glaucomatous attack, and always controlled by eserin.

61. C. R. Elwood: I have had one case in which atropin undoubtedly aggravated if not caused an attack of glaucoma. Mrs. B., aged 23: Ten days previous to my first visit patient complained of severe shooting pains through temples, and had called a general practitioner, who on finding the eyes much inflamed prescribed atropin and hot boric acid compresses. At the time of my visit vision in the right eye was limited to form perception and in the left 20/80 minus, tension increased and the asthenopic symptoms were so pronounced that the field of the left eye was unreliable. A continuance of the hot boric acid compresses and internally the administration of liberal doses of the iodids and salicylates, with instillations of eserin and night pilocarpin sweats relieved the symptoms and restored vision in what was to me a gratifyingly short time of four days. There was no evidence of iritis, and the result of medication led me to make a diagnosis of acute glaucoma.

65. C. W. Hawley: I saw one case in which homatropin and cocain were instilled and within one hour double acute glaucoma was produced in a man of 46 years of age. No relief followed the use of eserin, and on the third day a double iridectomy was performed with complete relief. I hardly would say that homatropin and cocain in this case were the direct cause of the symptoms, simply being an acute attack of a condition already present.

68. Edward Jackson: I have seen but one case in which a glaucomatous exacerbation was produced by a mydriatic This was in a woman aged 25 years. I precede the use of a mydriatic or cycloplegic in all cases by an ophthalmoscopic examination and a consideration of the probability of glaucoma.

70. C. H. May: As a rule I do not use a cycloplegic in patients beyond 45; in nervous individuals, especially women, I employ homatropin 2 per cent. combined with cocain 1 per cent. I do this also if the first glasses prescribed do not give satisfaction. This applies to patients 45 to 50. In such cases I use a cycloplegic, probably in 10 per cent. of cases. After the age of 50 I rarely use it.

In about 10 per cent. of cases between 45 and 50 described above the use of cycloplegics leads to more accurate and better correction both of astigmatism and latent Hy. (for latent Hy. does exist in quite a number of instances, notwithstanding the many views to the contrary.)

71. Ellis Phillips: I had one case, a woman about 45 years of age, whom I asked to put a solution of atropia, gr. ii

to ʒi in her eyes three times a day for two days; she put it in twice and then sent for me to call, complaining of marked pains in the head and eyes and colored light about the lamps I had no ophthalmoscope with me, and was not sure of increased tension. I prescribed eserin solution, and in a few days she was all right. This was the only case that gave me anxiety.

75. Wendell Reber: I have personal knowledge of but one case of true glaucoma induced by the use of homatropin after 45 and in that case (a hospital one), I believe closer ophthalmoscopic study would have prohibited the use of the mydriatic.

83. J. L. Thompson: I can recall but one person in whom the glaucomatous process was temporarily set up after the use of a mydriatic. This occurred in a young married woman aged 42. It subsided in a few days after the application of a weak solution of eserin.

Doubtless the reason why I have not met with more cases is because I take great pains in examining the tension of all persons nearing 42 years of age before using cycloplegics. If there is the least suspicion of tension, or if the patient mentions any idiosyncrasy concerning the former use of any of the mydriatics, I then examine as best I can by other means.

CONCLUSIONS.

No age can be arbitrarily fixed beyond which cycloplegics must not be used, and while they are as necessary in certain cases after 45 as they are before, they are required in fewer and fewer cases as life advances. But since there is more danger of glaucoma in the elderly, and as mydriatics tend to increase intraocular tension, these drugs should be used with caution after the age of 40, and in certain cases should not be used at all.

DISCUSSION.

Dr. Herman Knapp, New York—I have used cycloplegics in strong solution after operations for glaucoma, for the reason that in a number of cases you find a day or two after the operation that there are a number of fine, filiform adhesions, which in all probability are the result of blood or some irritating substance. I find that atropin dropped into the eye on the first day after the operation, while the eye is still soft, does not increase the tension. I have never in this practice, which is not new with me, seen any unpleasant result.

As to the production of glaucoma by atropin, homatropin and euphthalmin I have seen it repeatedly, in every one of them, frequently with atropin, less so with homatropin, and rarely with euphthalmin, viz., in three well-developed cases, increased tension, to plus 2, steamy cornea, and dilatation of the pupil, all the symptoms of a glaucomatous attack. Those attacks have not induced me to abandon euphthalmin, for they are easily cured with eserin; not so well with pilocarpin. One case of euphthalmin in which the remedy had been used for 6 months had developed well-marked atropin granulations. This suggested the idea to me that euphthalmin was in all respects a weak atropin, but using it in a patient with marked idiosyncrasy against atropin, it failed to produce erythema or any other irritation.

Dr. John E. Weeks, New York—I think there is a general impression that a mydriatic should not be used in glaucoma, even after the operation of iridectomy. In my association with Dr. Knapp I think it was very seldom that a mydriatic was used after an operation of this kind, but I found that the late Dr. Noyes made it a routine practice to use atropin immediately after iridectomy for glaucoma and continued it for two or three days, or until the wound was well closed. I think many of us have observed the adhesions Dr. Knapp has spoken of in the healing of the eye after iridectomy for glaucoma. I have used atropin in this way and have not regretted it; however, if there is no evidence of any irritation of the iris I would not use it after the first instillation.

In regard to the question of glaucoma being produced by mydriatics, I have observed one case after the use of cocain; at least the attack of glaucoma came on a very short time after its use, a half hour I think. There was a previous glaucomatous tendency. Cocain was employed in order to permit of a better view of the interior of the eye. I do not think the attack would have come on if the cocain had not been used.

Dr. S. D. Risley, Philadelphia—It has not been my habit to use a mydriatic after iridectomy for glaucoma, and it seems to me that it might not always be free from danger. I recall one instance where atropia was instilled by mistake in one of my cases of glaucoma at the Wills Hospital. Relief had followed the iridectomy and all was going smoothly until the third day, when I found a return of pain and increase of tension. The nurse then told me that atropia had been used by mistake. It is true the anterior chamber had been restored. Dr. Knapp, I understand, used it before the healing of the wound.

Regarding the occurrence of the conjunctival trouble alluded to by Dr. Knapp, I have seen the same thing follow the prolonged use of eserin in chronic glaucoma, but it may have been due to micro-organisms in the solution as suggested by Dr. Weeks. There were two instances, however, where the solution of atropia, coming from my own druggist, caused this conjunctival disease, notwithstanding the care habitually used to supply sterile solutions. They are unquestionably, I think, cases of idiosyncrasy to all mydriatic solutions, but I have never seen any evidence of this peculiarity for eserin.

Dr. F. W. Higgins, Cortland, N. Y.—I expect to hear more about the subjective symptoms following the use of mydriatics in old people. Dr. Starkey's paper refers more particularly to the use of atropin in refraction. It is very unfortunate that for months and even years after the use of a mydriatic patients refer every eye symptom to the instillation of the drug. Of course in children the symptoms fade out in a very short time, and you can brush away their complaints, but in people about middle life, or beyond, these symptoms are not always altogether imaginary. At a time when accommodation is beginning to fail, completely paralyzing it for several days may certainly be productive of untoward symptoms. For this reason I am sure that where it is possible we should examine these patients several times rather than subject them to the use of atropin to finish our diagnosis in one day.

Dr. John O. Reynolds, Dallas, Texas—Dr. Starkey reported me correctly in saying that I have frequently employed mydriatics in operations for glaucoma and glaucomatous cataract, and I feel that it is a reasonably safe procedure for the first two or three days following the operation, before the wound has closed, but I want to be placed on record as giving a caution as to its use in other kinds of operations that do not involve the opening of the globe. If you have opened the globe there is not so much danger, but I recall several cases presented to me where glaucoma had developed after using even cocain where an operation was performed that did not open the globe. One patient was brought to me completely blind following an operation under cocain for the removal of a pterygium. So when doing any operation that does not open the eyeball, and after presbyopia has developed, and with use of mydriatics, you should keep the patient under close observation and use a myotic afterward if pupil does not promptly return to normal size.

In the matter of refraction in presbyopes I use mydriatics, not cycloplegics, and keep the patient in my office until I see the pupil go down. I do not want a presbyopic patient who comes from a distance and uses a mydriatic to go away until I feel satisfied that everything is all right.

Dr. H. B. Young, Burlington, Iowa—I want to say, in connection with the use of cycloplegics in refraction, in people over 45, that I use them, not very often, perhaps, but occasionally in strong, robust persons, who seem to have an excessive amount of accommodation. I believe these people are not liable to glaucoma, because I understand that failure of accommodative power is one of the prodromals of glaucoma. I have had glaucoma follow two cataract extractions that I believe was due to atropin, in a patient 79, and in another 42 years of age. In the first case I used it because a colleague had operated on the other eye and had failure because of iridocyclitis. Twelve hours later I was called to find the patient with acute glaucoma. Eserin controlled the attack and result was satisfactory. In the second case, a teacher, I operated on the left eye at one vacation time and was unable to remove all the soft cortical matter. A rather mild iritis followed for about two weeks, with final absorption of the cortical matter and a good result. She subsequently came for operation on the other eye, and suspecting from the appearance that I would again meet with some difficulty in dealing with the cortex, I used atropin, which I had not used in the other eye. In five days there was increase of tension and I had to resort to eserin. I was pleased to hear Dr. Knapp make the statement he did as to the use of atropin after iridectomy for glaucoma. If I had had the courage to use it in a recent case some filamentous adhesions to the capsule might have been avoided.

Dr. J. A. Lippincott, Pittsburg, Pa.—I may say, however, that in my early practice I was in the habit of using a cycloplegic, atropin, much more frequently in elderly people than I do now. A good many years ago I produced glaucomatous phenomena in two cases both about 50 years of age by the instillation of this drug. Both cases responded promptly to a myotic, and no harm was done; but since that time I am rather cautious about mydriatics for refraction purposes beyond middle life. Still, we occasionally meet with cases even above 50 years of age in which the accommodation must be paralyzed to secure satisfactory results. In such cases, after a careful inspection and palpation of the eyes, I usually begin with a weak solution of homatropin, and watch the effect closely. If no unpleasant phenomena appear I proceed as in a young person.

Dr. Edward Jackson, Denver—In reference to Dr. Starkey's conclusion that cycloplegics should be used with caution after 40, I would amend that by striking out "after 40." They should be used with caution always. The only case in which I have seen glaucoma produced by a cycloplegic was in a young woman of 25; and in that case I think there is no doubt that if a more thorough investigation of the history had been made before using the drug a positive diagnosis of glaucoma would have been made.

It is true that patients often have a tendency to ascribe everything that happens in the way of eye symptoms for some time afterward, to the drug that has been used. If a patient has used atropin and then spends ten days or two weeks with nothing to do but think about his symptoms, it is likely that he will refer some of them to the use of the drug. The risk of that, of course, is very much lessened by the use of the brief mydriatics. That is, perhaps, the chief reason why they should be used after 45. But this risk can also be diminished by carefully warning the patient that the symptoms will not pass away after the use of atropin for at least two weeks. They are anxious about the effect until recovery is absolute. Apart from that danger I think there is the same need to use strong cycloplegics in some cases after 45, and even after 50, as in younger patients. In my experience where there is spasm of accommodation it yields more slowly as the patient gets older. There are a number of cases where it is just as necessary to use a cycloplegic after the age of 50 as before.

Dr. W. H. Bates, New York—I would like to record the history of a patient in whom atropin produced a very unusual effect. The patient was not 45, but a young girl of 18 Atropin had been used once with no bad effect. Later she was placed a second time under atropin, 2 gr. to the ounce, three times a day for two days and it was then discontinued. The pupil did not contract, but remained dilated six months, when it began to contract. The paralysis of accommodation continued. I saw the patient ten years later and there was still paralysis of accommodation.

Dr. Starkey—With regard to glaucomatous exacerbation being relieved by pilocarpin and eserin, I would say that in the one case I mentioned there was considerable difficulty, though both were used, and for a number of days I could not get the tension down and then it seemed prone to rise again.

In regard to the accommodation being so much weaker after 45, there is a difference of opinion expressed about that in the replies sent in. While some say that after 45 they use weaker or less amounts of cycloplegics and others that they use only homatropin and cocain, two or three say that they have to use stronger cycloplegics and for a longer time in order to get complete relaxation than they do in younger people.

CARCINOMA EPIBULBARE PLANUM.

B. MATYS, M.D.
ASSISTANT TO PROFESSOR DEYL, AT THE BOHEMIAN EYE CLINIC.
PRAGUE, AUSTRIA.

Epibulbar tumors are those which are localized on the margin of the cornea, where it joins the sclera (limbus corneæ), from which they spread over the cornea and conjunctiva, sometimes also in the sclera. They do not include secondary tumors occurring in the ciliary body, choroid or lids. Among the more frequent benign tumors occurring here are dermoid, fibroma and lipoma; the malignant forms being mainly sarcoma and carcinoma. The early diagnosis of these, especially the latter, is of the greatest importance, since by its timely removal the eye may be saved and, according to the testimony of medical literature, without any recurrences. The epibulbar tumor in our case was flat, peculiar in appearance and color, unusual in this respect among the malignant forms, but certainly belonging to the epibulbar tumors. Noyes had met with only three cases in seventy thousand patients. In the out-department of the Bohemian Eye Clinic, Prague, thirteen cases have occurred out of a total of eighty thousand patients during the last ten years, and Professor Deyl, now at the head of the ophthalmological clinic, affirms that he saw no such conjunctival tumor during his experience as assistant and in his polyclinic practice of fifteen years nor in his private practice, during which time he has observed or treated more than one hundred thousand cases.

NARRATION OF CASE.

Our case was V. J., 78 years old, miller by occupation, resident of Borosin, Bohemia, who was received into the Bohemian division in May, 1902.

Previous History.—He states that he had not been ill during the past fifty years, but before that time he had had gonitis rheumatica, but never any eye illness. His vision had always been better for near than for distant work. One and one-half years ago the left eye became inflamed and some lachrymation was noticed, and he had such pains from 11 to 3 o'clock at night that it was impossible for him to sleep during these hours. Six weeks after the first appearance of these pains he noticed that his eyesight was failing, and two months later (just at Christmas) his daughter told him that he had a white spot on his eye. From this time on he had no rest. The eye became more reddened, his vision continued to fail and the white spot increased in size. The patient was unable to say where the white spot first appeared. During the day he had no pain, but at night regularly from 11 o'clock to 3 the pains were so severe that he could not sleep. Besides this he was troubled more with lachrymation. He consulted no physician, but was satisfied with remedies his neighbors suggested.

Condition on Entrance.—Patient in good health aside from hypertrophic prostatitis and his eye disorder. The right eye, aside from chronic catarrhal conjunctivitis and myopia modica, is normal. In the left eye the lids were normal, the conjunctiva of the lids a little inflamed and edematous, the fornix slightly edematous and injected. The tumor is located in the lower half of the bulbar conjunctiva. It takes in the conjunctiva from the limbus cornea to the fornix irregularly, so that in the lower external quarter where it is broadest it measures 1.5 cm. There is a small extension into the superior external quarter, here touching the limbus, and it also extends downward so that a little of the tumor is seen occupying the inferior nasal quadrant. The tumor encroaching on the cornea a distance of two millimeters is irregularly margined and very well defined, so that at no place does it enter into the cornea. From the healthy conjunctiva, where the arteries are larger, the tumor is well limited with irregular margin and is raised 1.5 millimeters above the normal surface. The highest point of the tumor is in the inferior external quadrant, measuring 3 millimeters in thickness and 3 in diameter. The tumor is movable with the conjunctiva, the general tint is white. At the limbus it is a chalky white, while 3 millimeters from this point, that is, toward the lower border, it is dirty white and somewhat reddish. The surface of the tumor is slightly roughened, squamous and nowhere ulcerated. No arteries can be distinguished in the tumor, its consistency is hard. Cut No. 1 shows the exact localization of the tumor and its irregular outline. The surrounding conjunctiva is slightly injected.

Fig. 1.—Photograph of the eye. Location of the tumor

In the examination of the remaining portion of the bulbus we find an incipient senile cataract and opacity of the corpus vitreum, together with a small degree of myopia. His vision is 5/30 (Snellen), with minus 2 D. equals 5/15.

The tumor was removed by one cut with Graefe's knife after the conjunctiva had been severed with the scissors around its entire margin. This enabled us to see that the tumor had been connected at its base with the limbus; in the inferior external quadrant it had been connected with the sclera only by a pedicle corresponding in place and size to the thickest portion of the tumor. These points or places of attachment were scraped with a sharp spoon, followed by cauterization. The entire wound was covered with the adjoining conjunctiva, held in place by two stitches. The wound healed in a week's time. After the operation the growth was put into 5 per cent. formalin alcohol. It was next put into celloidin, then the entire tumor was cut in the usual way with the microtome and stained with hematoxylin and paracarmin.

Macroscopic examination of the tumor while cutting it revealed its varying thickness, ranging from 3 millimeters, located as stated in the external inferior quarter, to the thinnest portion extending over the sclera and along the limbus, measuring ½ millimeter, or even less. The greatest diameter of the tumor was 2.5 cm.

THE MINUTE STRUCTURE OF THE TUMOR.

The microscopic examination will be reported, taking the cut sections from the lower border of the tumor upward to the cornea, where it ended. With low-power magnification we see in the first section the normal epithelium of the conjunctiva, and beneath it a little connective tissue. The conjunctival epithelium is stratified pavement cells with well stained nuclei. The cells at the base are cylindrical and becoming flatter from below upward. In this it is like the normal conjunctiva except that there is a round cell infiltration. Viewing the conjunctiva from below upward we find the epithelial cells gradually increase in size, and at the point where the tumor begins we find bands of epithelial tissue passing into the tissues below. In these bands we see epithelial cells concentrically arranged, with colloid areas here and there, producing the nest cells so characteristic of carcinoma, which are divided in the section in all directions; we also see round cell infiltration and dilated blood vessels. The surface epithelial cells are not very different from the normal; those, however, in the bands passing downward are increased in size, with mainly round nuclei; the nucleoli are readily seen with a low-power lens. Epithelial cells in the nest cells reveal bodies of keratohyalin (Fig. 2).

Examining a higher section, we see the epithelial cells of the surface changing in character. A layer of epithelial cells is to be seen here, as is seen in cells of the epidermis in the stratum granulosum. The cells here are flatter and contain much keratohyalin, which again is covered by typical cornea epithelium, as in keratosis cutis, which ends in the margin of the cornea and also corresponds to the place in the macroscopic examination where the tumor was chalky white and squamous (as seen in Fig. 3). The bands passing downward are broader, not so much divided as the bands in the previous section of the conjunctiva (see Fig. 4), and the cell nests are not so frequent.

When we examine the part of the tumor which is over the cornea we see that the fibrous papillæ are lower and the entire tumor decreases gradually, changing into the normal corneal epithelium. In those places where we see stratified epithelium the margin of tumor and normal cornea can be very well made out. Where the horny cells terminate the basal cells of the tumor gradually change to the normal basal cells of the cornea. The cell protoplasm is deeper stained (as shown in Fig. 5) and the preparations show that the elastic membrane (Bowman's) sharply divides the proper substance of the cornea, which is unchanged from the tumor. The bands (papillæ) are also here lacking. The entire tumor is well infiltrated with round cells. With low-power magnification we see that the entire tumor is in the epithelial conjunctiva. With higher magnification we perceive that the epithelial cells of the surface located at the limbus are horny epithelial cells, under which we find cells containing keratohyalin which cause the chalky white color seen without the microscope. Below the limbus the tumor is of a pale milky color, which is explained by the presence of bands and cell nests containing colloid material, which are more numerous here than they are above, and which also make it impossible to see the blood vessels on macroscopic examination, though these latter are revealed by the microscope.

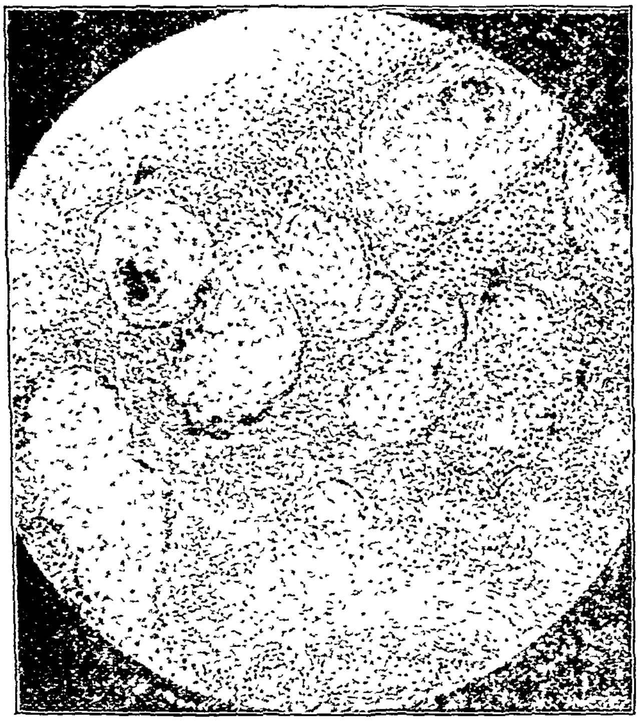

Fig. 2.—Microphotograph of the tumor in the conjunctiva showing cancroid epithelial bands and nest cells.

The microscopic examination shows us that the tumor is a carcinoma, as it contains cell nests containing the colloid material in the epithelial bands and its extension in all directions is also characteristic of cancroid tumors. But ulceration, which is so common in carcinoma, does not appear to have occurred.

In our case, as is usually the rule in epibulbar tumors operated on late, there was a recurrence on the sixteenth day after the operation. In the inferior external quadrant of the cornea a small point or macula about 1 millimeter in diameter made its appearance and was again removed and the spot cauterized. The microscopic examination of this recurring growth showed the same structure as the original tumor. Six weeks later three points of recurrence were again removed from the limbus in the inferior half of the cornea. At the beginning of August, two months after the operation, the condition was as follows: The eye was quiescent. The conjunctiva had healed very favorably, but in the two lower quadrants it was drawn tense toward the side of the original localization of the tumor, where it was firmly adherent. In the external inferior quadrant, 1 cm. from the limbus, the conjunctiva was somewhat edematous, and beneath it could be detected on palpation a swelling of cicatricial tissue 9 millimeters in circumference. In the limbus no recurrences appeared. Instructing the patient to come back instantly as soon as he noticed any white point or change in the appearance of the eye, he was discharged. He returned again for treatment at the beginning of November with two recurrences located in the inferior external quadrant, one at the limbus about 5 millimeters in circumference, the other in the conjunctiva at the point of the existing edematous cicatrix measuring 2 millimeters in circumference. It was not possible to remove these recurrences at this time, as he had an attack [illegible]hiolit[illegible] and bronchitis. The recurrences did [illegible]

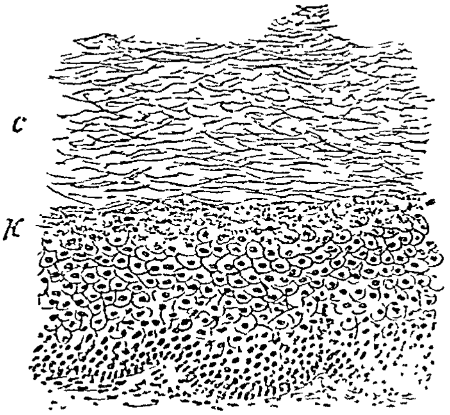

Fig. 3.—Section of tumor in limbus of cornea. C. Horny stratum. K. Stratum of cells containing keratohyalin.

as we looked for them on account of the large size of the tumor. Therefore, only a conservative plan of treatment was possible at this time, as we did not look for immediate trouble in spite of the presence of the new growths, and as the eye had fair visual power enucleation was not seriously thought of.

In our patient there appeared to be a direct relation between the carcinomatous tumor and angioma contrary to the recently expressed opinions in the literature on the subject of angioma and telangioma. It was noticed that our patient had some small pin-head angiomas in the skin of the breast and also very numerous small lentigines. As regards the statistics of carcinoma it may be remarked that in this region such epibulbar tumors are very infrequent. This rare case is published mainly on account of the practical points involved. As regards its etiology, it may be said that we found nothing giving evidence either in the clinical or microscopic examinations of any parasitic origin.

The special practical point of the case to which we will call attention is the common error, so liable to be made, of neglecting an incipient tumor occurring at the limbus or its vicinity. The chief condition with which it is likely to be confounded is phlyctenular ulcer. The celebrated von Graefe made an error of diagnosis in a disease occurring at the limbus. He said that at the first examination he did not make a very careful study of it and so diagnosed a case of carcinoma as a phlyctenular ulcer, and our case had also been previously treated as such by a general practitioner. It appeared, however, in a man of 78, and in our experience phlyctenular ulcer is especially a disorder of children, but we must not overlook the fact that it also occurs in the adult, and even in old age, hence the importance of the differentiation.

Phlyctenular ulcer in the limbus or near the limbus appears as a white spot in the conjunctiva surrounded by inflamed conjunctiva and no arteries are to be seen in the phlyctenule itself while numerous vessels run to the border of the cyst, but none can be traced running over it. Unpigmented sarcoma and carcinoma also start as a grayish white cyst with highly hyperemic surrounding conjunctiva, the remaining portion of the conjunctiva being unchanged. The phlyctenular cyst usually ruptures on the first or second day, leaving an irregularly margined ulceration. This does not occur in tumors except in cancroids or carcinoma planum where the ulceration appears late, occurs in the center of the growth and leaves a lesion surrounded by a hard or indurated wall. In our case no ulceration took place, the superficial layers of the tumor being as hard as callus. Phlyctenular ulcers usually occur in both eyes, and patients have suffered repeated attacks of inflammation during childhood, usually leaving some maculæ of the cornea, blepharitis eczematosa and rhagades of the nostrils. They are improved or cured in a few days with the use of calomel or Pagenstecker's ointment. The contrary to this is the case with tumors. They usually occur in one eye and in old age, and not in young adult life.

Finally, the following difference between phlycentula and tumor in the cornea is to be noticed: In phlyctenules a thick infiltration occurs in the cornea and conjunctiva with later ulceration, leaving an ulcer with irregular wall and infiltrated surrounding tissue. In carcinoma or sarcoma we find a small tumor with smooth walls irregularly protruding over the surrounding surface. In the second place we must differentiate it from inflammation of the sclera (episcleritis). In this disorder we have a small swelling close to the limbus, purplish in color. The conjunctiva over the swelling is injected, otherwise unchanged. Such a swelling may lead to error, which may be mistaken for tumor of phlyctenular ulcer. The conjunctiva will give us the clue in case of doubt, as it is movable over the infiltration in the sclera in episcleritis only, and beneath it we may find on palpation a small swelling of variable size and of hard consistency.

Further, we have the differential diagnosis from vernal catarrh, which is characterized by the hypertrophy of the conjunctival epithelium, corresponding to the palpebral fissure, in location reaching the limbus and rarely ever surrounding the entire cornea, seldom extending over it, and furthermore, of hard consistency, and it is irregularly prominent with grayish white borders. Microscopic examination reveals hypertrophy of the epithelium, as also in tumor, but in spite of this it is a non-malignant disorder. Vernal catarrh usually appears in young children and involves both eyes. Its duration is for years. Its exacerbation during the summer and remissions during the winter months will always enable the practitioner to make a correct diagnosis. Vernal catarrh is usually accompanied by hypertrophy of the palpebral conjunctiva, which is rough in appearance and milky white in color. Lastly, the rate of growth is different from that of sarcoma and carcinoma, being more rapid in the latter. In the differential diagnosis between sarcoma and carcinoma we especially here consider only the more prominent carcinomatous tumors (carcinoma luxurians) and the flattened variety, as in our own case (carcinoma planum). Sarcoma is hard, has vertical margins; carcinoma is usually soft and can be easily lacerated. It is not abruptly margined as in sarcoma, but graduates more into the tissues. In spite of these differences the differential diagnosis is sometimes impossible without the microscopic examination. One-third of these tumors, carcinoma and sarcoma, are melanotic and graver in their prognosis than carcinoma planus (cancroid).

In conclusion, I must acknowledge my indebtedness to Professor Deyl for material help given me in preparing this paper, for which he has my thanks.

LABORATORY INSPECTION OF VACCINE.

ADOLPH GEHRMANN, M.D.
CHICAGO.

In this paper the term vaccine is used in the restricted sense, meaning smallpox vaccine. The purchases of vaccine by the Chicago Department of Health have been subject to inspection and test of each lot received since 1894. During July, 1894, an extended investigation of vaccine was made and showed that glycerinated lymph contained fewer bacteria and had a longer period of efficiency than the dry vaccine points. Glycerinated vaccine was therefore introduced and has been used exclusively ever since. The exact date of the first distributions was Aug. 1, 1894. The points herein brought out are consequently based on the inspection of this supply of the glycerinated product. There have been distributed to the vaccinators approximately one million individual vaccinations from that date to this. Some 20,000 tubes have been used for the purpose of testing; 10,000 for the bacteriologic and animal experiments and 10,000 for the clinical tests.

Every lot received is sent subject to approval and is accepted only after full completion of the observations.

It has been further understood that the department reserved the right to destroy any lot that did not meet its approval. Vaccine has been destroyed on several occasions when found inert, but when rejected because of bacteria it is usually returned to the producers with instructions to allow it to mature before being distributed.

STANDARD REQUIRED.

Deliveries are made in lots of 5,000 to 10,000 vaccinations. Only individual tubes are used. For each lot the following conditions must be fulfilled:

The lot must be from one operation; that is, it must bear the same laboratory number throughout.

The dates on the packages must not precede or exceed the time limit of efficiency. Sixty-day emulsion with 40 to 50 days for the period of use.

The physical conditions must show a uniform emulsion.

Cultures made must show an absence of pus bacteria.

Cultures made must show at least a relatively small number of saprophytic bacteria.

The injection of the mixed contents of 10 or 12 tubes into a guinea-pig must be negative.

The clinical test must give not less than 90 per cent. in typical results in primary vaccinations.

SELECTION OF SAMPLES.

From all parts of the lot 100 tubes are selected; these are marked and reserved for the test. We have found this number ample to insure accuracy. As a general precaution advance sample lots are obtained from producers and tested in the same way as the actual supply. By this means a double check is maintained. This testing, together with the producers' private control, should prevent any failure to detect possible defects.

SPECIAL CONSIDERATIONS.

Soon after the introduction of vaccine in sealed tubes it was noticed that a separation of the more solid particles, epithelium, leucocytes and detrites, took place from the glycerin if the tubes remained quiet for three or four months.

The vaccine as now prepared consists essentially of ground-up epithelium in a variable percentage of glycerin and water. If this mixture is not accurately adjusted, a matter dependent on the experience of the producer, it may be too thin and a separation takes place after a time. We have been able to show that tubes in which such separation is apparent will give a larger percentage of failures in the clinical test than if it had been recently tubed and still in proper emulsion. The reason for this is evidently that the thin glycerin is blown out and does not carry with it a sufficient amount of the virus.

For the culture test it would seem that the use of inclined agar answers all requirements. Each single tube is blown out on the agar surface and spread with the aid of the condensed water in the bottom of the tube. This water also dilutes the vaccine and prevents the further restraining action of the glycerin. The inoculated tubes remain in the incubator for 48 hours and then at room temperature for a further period of three to four days. Petri plates of agar and gelatin have been used from time to time, especially when an actual count of bacteria present was desired. As the qualitative determination is the principal point sought, the agar tube culture is sufficient for this purpose. During the spring of 1896 experiments were made to determine the value of strong antiseptic treatment of the vaccinated area on the calf before scraping off the vaccine, as a means of reducing the numbers of bacteria usually found. It was shown that material with few bacteria could be obtained, and in several instances entirely sterile fresh vaccine was made. Clinical tests of this, however, gave poor results and total failure for that which was sterile. There is a mean that must be followed in producing the virus. It must be as clean as possible, but can not be made initially sterile by using antiseptics. The identification of the bacteria is made by the usual methods.

Saprophytic bacteria are not to be overlooked. They do not develop as rapidly as the pus cocci, and on this account the culture must be kept under observation for several days. The absence of these species indicates clean production. On numerous occasions *Bacillus subtilis, Cladothrix dichotoma* and varieties of moulds and yeast have been present in such numbers that the vaccine had to be rejected on this account.

Animal experiments are made on guinea-pigs. About 10 to 12 tubes are evacuated and the contents mixed with a small quantity of bouillon and injected subcutaneously. This part of the test is made when the tube cultures show a sufficient reduction in the number of pus bacteria.

From the animal experiment the presence of *B. tetani, B. tuberculosis* or other specific pathogenic bacteria should be determined. After making several hundred inoculations I have not had a single animal die of tetanus or show tuberculosis at the point of injection. These bacteria occur with extreme rarity in vaccine, and probably in the few cases where they have been reported they could have been found in considerable numbers.

The time required for these experiments is 4 or 5 days. Cultures are made first, which in the incubator will indicate as to pus bacteria in 18 to 24 hours. These tubes are now put aside for growth of saprophytes for 3 or 4 days. In the meantime, providing that the culture result was satisfactory (few or no pus cocci), the animal experiment is made. The clinical test is next started, and requires a further 10 days for completion. If this shows 90 per cent. typical the lot is passed for distribution. Fourteen days, therefore, is thus used in establishing the quality of the product, and this should give at least 30 days in which the vaccinators can use their supply with every assurance of a safe and successful result.

Laboratory of the Department of Health.

Professional Unselfishness.—It might almost seem to a philosophical observer as if the leaders in this movement had unselfishly made up their minds to prove to men and women that if they had more common sense they would promptly abolish the medical profession by taking away its *raison d'être.* One seldom hears of a lawyer exhorting his neighbors to avoid litigation so that they may not require his services. Yet every reputable physician is expected not only to cure diseases, but to give his patients such hygienic advice as may prevent them from needing him again. This is a good deal to expect of human nature in individual cases; but the problem which is at the present moment most strenuously attacked by the medical men of Europe and America is how to reduce the number of their patients and the amount of their own income by 10 per cent. at one fell swoop. At least one person out of every ten dies of pulmonary tuberculosis and other forms of tuberculosis, and it is this disease that physicians are now striving with all their might to exterminate utterly, or at least to limit as much as possible. Since tuberculosis is rarely contracted by the medical practitioner, his labors in striving to eliminate it from his practice accordingly stand as a remarkable exemplar of humanitarian altruism.—"N. Y. Evening Post."

CHEMICAL INDIVIDUALITY.

There are abundant evidences of the chemical differentiation of species, which in some instances is as prominent as the morphologic distinctions. For example, we find specific varieties of hemoglobin, which, although functionating similarly in all animals, and with closely related composition, yet show quite different crystalline forms. Probably the differences in the effects of drugs on different animals depend on different chemical composition of certain parts of the animals. The entire work on immunity testifies to these chemical peculiarities of divisions in the animal kingdom. Even natural selection plays a part in such differentiation, as seen in the protective colorings, the venoms, the defensive odor of the skunk, or the ink discharged by the cuttle-fish. The peculiarity of proteid metabolism by which in reptiles and birds the chief end product is uric acid, while in mammals it is urea, has been the pivotal point for most of the study, theorization and contention that have made "uric acid diathesis" familiar even to the laity. Now, while the morphologic differences in animals are plain, and therefore the chief basis for classification, the chemical differences are for the most part equally obscure, and hence of little use in systematic classification. Still it is altogether possible that as physiologic chemistry becomes more developed, and the methods more refined, the chemical relationships may help out in places where morphology alone is confusing. Probably the best example that can be cited of accomplishment in this direction is furnished by the precipitins of serum, as used in the medicolegal test of blood or other proteid constituents or secretions of the body. The serum of an animal immunized against human blood will precipitate in certain dilutions besides human blood the blood from not one of the vast number of allied and remote varieties of animals except certain of the higher apes. The relationship between the apes and man, based entirely on morphology, receives suddenly confirmation from an unexpected source. As these precipitins are in a high degree specific, serving to differentiate animals that are not very unlike, this fact indicates strongly not only a common origin of man and the apes, but also that some very peculiar constituent of the blood serum of the common ancestor has passed on unchanged through the widely divergent lines of descendants.

Not only are there differences in the composition and metabolism of different species, but even in a single form there are variations in metabolism that may sum up under certain conditions until they crop out suddenly in what may be called a "chemical sport." A. E. Garrod[1] discusses this matter in an entertaining way in his article on "Alkaptonuria." Alkaptonuria is a peculiar and uncommon condition in which the urine contains homogentisic acid, a substance that is related to tyrosin, from which it is probably derived. Although rare, it is so striking that it is likely to attract attention, for the homogentisic acid has the property of turning dark after exposure to air, and of staining fabrics deeply. Physiologically considered alkaptonuria is interesting in that it seems not to indicate a disease, but is rather an unusual method of metabolism, generally congenital and lasting throughout life. A certain amount of tyrosin does not pass through the usual steps of metabolism, but is excreted in this form, without giving rise to symptoms and seemingly without injury. If present at all it exists in considerable quantities, usually 3 to 5 grams daily, and is never observed in traces. It is distinctly a family disease, for of 32 known instances 19 have occurred in seven families, in which there were altogether but 29 normal members.

Of particular interest in connection with this chemical individuality is the frequency of consanguineous marriages in the immediate ancestry of alkaptonurics, for among 19 cases in which information on this point could be obtained, 60 per cent. were the offspring of marriages between first cousins, and in one the condition was transmitted from father to son. Mendel's law of transmission of characteristics seems to Garrod to offer an explanation. If a tendency to the production of a rare recessive characteristic exists in two individuals the offspring may show the characteristic strongly developed; in marriage of cousins such a rare tendency as this one would be more likely to be present on each side than in ordinary matings. Albinos offer perhaps another instance of similar conditions. Albinism is a chemical phenomenon, depending on a failure of formation of melanin, and it occurs in undue proportion among the children of consanguineous marriages. Retinitis pigmentosa, which in a way is the chemical opposite to albinism, occurs to a remarkable degree among the offspring of cousins. These are all instances of chemical abnormalities that are of such a nature that they can scarcely escape observation. It is perfectly possible that there are many less obvious chemical abnormalities that escape detection. They are interesting in that they indicate that perhaps just as no two individuals are identical in their morphology, so there are differences in their chemistry. Sometimes tendencies are added together by marriage of relatives, and the sum appears in some anatomic peculiarity on the one hand, or as an albino or alkaptonuric on the other. Again, the tendency develops suddenly into a distinct characteristic, and a sport is developed without evident or adequate cause.

EPILEPSY (?) AND RAILWAY ACCIDENTS.

In recent communications to a railroad paper two experts on railway matters offer their explanation of the too frequent unaccountable accidents that occur. These are generally due to mistakes on the part of the engineer, who, though often long-tried and experienced, may suddenly fail in his duty in the most remarkable way. He may neglect a signal, over-run his time or disobey an order, and the consequence is disaster. The theory adopted by these writers is that locomotive engineers, owing to the nature of their occupation, are especially subject to nervous strain which develops in them a form of epilepsy in which their reasoning power or judgment is temporarily destroyed. One of them states that the concentrated attention required for long periods of time brings about a peculiar nervous disturbance that has many of the external appearances of petit mal. The other expert likewise considers that an epileptic factor is involved. This is bringing into play a serious symptom and seems to us more than is required.

There is no question that certain people under certain special conditions of health or mental strain may have their cerebral mechanism so thrown out of order as to fail them in important crises; a sort of self-hypnotism is perhaps not altogether uncommon. An expert railway man riding over a specially bad piece of road on an engine noticed that the engineer signaled to stop the train. Nothing wrong could be seen, but the man had developed an actual hallucination of sight and thought he saw at a particular spot a boulder across the track. In this case it was overcaution, but in other cases the reverse might occur. Railroad companies are not sufficiently considerate of their employes when they overwork them and subject them to special nervous strain by long hours. It is easy to see how the special faculties of meeting emergencies quickly, etc., may be dulled or even abolished by fatigue. A man who has been excessively overworked can hardly be considered responsible if he sometimes fails in emergencies. The companies should also look carefully into the habits of their employes. The engineer should consider his employment first and use his resting time in such a way that he will be in the best fitted condition for his work. Dissipation in the way of loss of sleep, etc., which may be entirely voluntary on the part of the individual, may lead to disaster.

The traveling public is certainly deeply interested in the matter, and in this country the traveling public includes nearly every one. It is not pleasant to think that one's safety is entrusted to a man who has more demanded of him than his nervous system is capable of performing, or to one who does not duly economize his energies in such a way as to bring about this same condition. The time will come, we hope, when railroad regulations will be so perfected that more careful scrutiny will be kept over engineers, conductors and those in similar responsible positions to insure that they will be at all times mentally and physically fitted for their responsibility. There may be epileptics acting as engineers, as appears to have been the case in some instances, and they should certainly be relieved of their responsibilities, but it is not necessary to drag in such a factor as epilepsy to account for accidents. There are many less formidable conditions which may, under certain circumstances, have equally disastrous results.

COSMOPOLITAN DISEASES IN THE TROPICS.

The concluding chapter of Scheube's translated work of Diseases of Warm Climates is devoted to medical geography, or what the author calls "cosmopolitan diseases." It gives a compendium of the facts, so far as known to the author, of the distribution of certain general diseases, and this has been made the subject of an interesting editorial commentary in the *Indian Medical Gazette* of March, 1903. While most of the so-called cosmopolitan diseases are pretty fairly distributed, there are some decided differences in their range, and some of the comments on Scheube's statements by the editorial writer are worthy of note. The editor thinks there should be a good deal more attention paid to the geographic etiology of disease. The same theories that apply in one country are not by any means always applicable in another. Hepatic cirrhosis, for example, which he thinks may be very properly called "gin liver" in Europe, can not be considered to be due to the same influences in India.

One of the curious facts pointed out by both Scheube and the editor is the absolute absence of scarlet fever in the tropics. While it may be imported into such regions, it never spreads, and it would be interesting to know what special causes in the temperature or otherwise there may be for this peculiarity. Erysipelas, which Scheube considers rare, is not at all unknown in India, and pneumonia, which is unevenly distributed, lacking in some regions, is almost as serious a disorder in Indian territories as it is in Europe and America. At the present day it has come to be more dreaded in some Indian jails and public institutions than even dysentery used to be. Another disease which seems to be lacking in tropical countries is acute rheumatic fever, not chronic rheumatism, and while it occurs, it is by far less frequent among the natives than is the case in other climates.

Sunstroke, which we attribute to temperature, is in fact rare in some tropical countries. Perhaps this may be due to the sanitary habits to which the residents have been educated in regard to it. The *Indian Medical Gazette* rejects Sambon's theory of a specially infectious type, the so-called "siriasis." Scheube fails to recognize insolation as a tropical disease so much as to give it a special chapter, though he notices it among his cosmopolitan disorders. This is a very interesting subject, worthy of close study and offers certain problems that will serve to occupy medical attention when once it is directed to them. A careful study of medical climatology and geography would certainly be suggestive as regards the measures to be taken to meet some of our more obstinate and serious affections. If scarlet fever can not exist in warm climates there ought to be some fact to account for it that might very probably be of utility in its management where it does occur, and similarly with other disorders.

RECENT STUDIES ON SNAKE VENOM.

Contributions from various workers during the past year have revealed important facts concerning the action of snake venom, and incidentally some gain has been made in our knowledge of the chemistry of "immunity reactions."

The important studies made are reported by Flexner and Noguchi in two articles,[1] Calmette,[2] Keys,[3] and recently Keys and Sachs.[4] The work of Flexner and Noguchi[5] has furnished, among others, the following important observations: Venom contains only intermediary bodies or amboceptors (no complement), and alone would not be of great toxicity; the normal serum of susceptible animals contains the substances (complements) which, by a conjoint action with the intermediary bodies of the venom, cause the toxic phenomena; the loss of bactericidal power of the blood of animals poisoned with venom (previously noted by Welch and Ewing) is due to fixation of the animal's complements by the venom; the serum of snakes contains very little complement for its own venom; snake sera owe their toxicity to hematoxin (hemolysin), cobra venom to its neurotoxin, and rattlesnake venom chiefly to a substance which they call hemorrhagin (an endotheliolysin, the effect of which is to impair the vessel walls, causing hemorrhage); the demonstration of toxoids in venom, and a proteolytic ferment. Other valuable observations are made, a good understanding of which demands perusal of the original; but it may be stated that support is added to the Ehrlich side-chain theory, by showing that the neurotoxic principle in venom may be fixed and abstracted *in vitro* by nervous tissue, which duplicates observations with tetanus toxin.

A short time after the first publication by Flexner and Noguchi, Calmette disputed some of their findings in a note to the Académie des Sciences, but he did not clearly grasp the nature of the reactions and substances he described. He made one very important observation, however, to the effect that a normal serum which was heated to 62 C. or above had a strong activating power for venom. As this temperature destroys ordinary complements he had discovered a new substance which he considered to be of the nature of intermediary body.

Keys was able to confirm the claim that cobra venom consisted of amboceptors alone, and, in opposition to Calmette, he supports the observation of Flexner and Noguchi that normal complement will activate venom. He also made the important discovery that the supposed *amboceptor*, or *sensibilisatrice*, as the French have it, of Calmette was in reality another sort of complement, which came into evidence only after normal serum is heated to 62 C. or even to 100 C. Painstaking study of this substance seemed to show conclusively that it is nothing more than the lecithin which is contained in normal serum; and since in certain cases the corpuscles (washed) themselves activate the venom, it was eventually proved (Keys and Sachs) that the lecithin which is bound in the stroma of the red cells also can play the part of complement for cobra venom. Keys and Sachs established clearly the non-identity of normal complement and lecithin complement, and discovered other substances which may act similarly: Kephalin, bile and milk (goat) when heated to 100 C. Their experiments lead them to conclude that probably it is the fatty-acid radical of the lecithin-venom combination which constitutes the active group.

Of the mass of facts marshalled by the different investigators mentioned two are of pre-eminent importance: the presence in the blood of certain complements may be in particular cases, as in venom intoxication, a source of great danger to an individual rather than a protection, and that definite chemical substances may be able to act as complements under certain conditions.

INTELLIGENT COWS.

In an interesting article on the "Milk Supply of Large Towns" in the *British Medical Journal*, March 28, we find the following remarkable statement: "The driver having finished milking, his cow offered to take me into an adjoining room where the milk was cooled, saying that while he fetched the manager I could have a look around." We submit that there has been nothing so remarkable since the days of Balaam. One would think that with such intelligent cows dairy reform would be easy. Notwithstanding the high authority of the *British Medical Journal*, we have our doubts as to the alleged fact.

EXPERT TESTIMONY.

In a recent trial in Detroit the judge criticised the law of Michigan regarding the admission of expert evidence as being defective. A physician was on the witness stand who, as a county official, had made an autopsy and a chemical analysis of stomach contents. In the cross-examination it was attempted to draw out his opinion on certain chemical points as an expert, his testimony having chiefly been as to facts. In response to objections made by opposing counsel the judge said the matter was a simple one; if the witness was not a fully qualified expert he ought not to be thus cross questioned, that the laws of Michigan did not fully cover this question of the admission of expert evidence, and that there should be further legislation on the subject. If we understand the judge's position, it is that there should be some legal regulation as to who is and who is not an expert whose opinion evidence ought to be admitted by the court. Every physician is supposed to know something of chemistry, bacteriology, surgery, psychiatry, etc., but only those who are specialists in these departments can rightly give an expert opinion. It seems to us that this Michigan judge has pointed out one of the most serious defects in our methods of utilizing opinion testimony, and one that, if remedied, would relieve at least medical expert testimony from a great deal of the opprobrium under which it at present suffers. If the law prescribed a certain standard of expertism, if it required any one testifying as an expert to prove that he had a certain amount of actual knowledge of or experience with the subject on which he was to give an opinion, and still more, if it required a recognized professional reputation as an expert in the specialty he professes to practice, there would be less talk of the worthlessness of medical expert testimony. As it is, in most parts of the country at least, any medical practitioner of any school can pose as an expert on any medical subject. This rule of requiring some proof of competency would not necessarily exclude venal experts, but there are fewer of these among those generally qualified than is perhaps supposed. A man with a genuine reputation will not be so ready to risk it for a fee or a series of them. Let legislation be passed rationally defining the qualifications of an expert, even a little arbitrarily, if it is impracticable to do otherwise, and we shall hear less of such tirades against medical expert testimony as that uttered a few months ago by a New York ex-judge. As it is, the legal profession has it in its power to obtain competent and honest expert opinion testimony if it wants it. The trouble is that, too often, it is not the kind it wants.

PLANS FOR BUILDINGS FOR THE ROCKEFELLER INSTITUTE.

We understand that the drawing of plans for the buildings of the Rockefeller Institute of Medical Research is imminent. We hope that those in whose hands the decision as to these plans lies will neither make the mistake of indulging in extravagant architecture, nor be guilty of an error, much more common among scientific men, of imagining that the nature of the building and the quality of the materials put into it are matters of insignificance for the success of the foundation. We are all familiar with the lamentable squandering of college bequests in unnecessarily pretentious buildings to an extent that has precluded the acquisition of men of eminence for the faculty and has paralyzed efficiency by failure to provide an adequate budget for maintenance and operating accounts; such misguided expenditure of capital can not be too strongly condemned. But we fear that, in some scientific circles, the value of good buildings of a permanent character and of dignified and sufficiently imposing exterior has been and is insufficiently appreciated. An idea is prevalent among many that a scientific laboratory should be built in so flimsy and cheap a manner that it may conscientiously be torn down and rebuilt to suit more modern conditions in the course of five or ten years. It is further gratuitously assumed that because great men have done and doubtless will continue to do great work in hovels and dungeons with the most meager outfit, that therefore proper housing and the liberal provision of equipment are matters which can safely be disregarded. We grant readily enough that if we had to choose between great men with poor buildings and equipment and mediocre men with elaborate buildings and extravagant equipment, there would be no doubt that we should decide to take the former, but we maintain that wherever possible the great men and ideal facilities should be brought together. Now that the unit system of construction with modifications of it has been introduced there is much less danger than formerly that in the course of a few years a building will become unsuitable for what it has been designed. Besides, the effect of noble surroundings on the investigators themselves has to be thought of as well as the influence of a dignified architecture on the standing and support of an institution in the community. It would be a misfortune, indeed, if the institute now being planned should make that mistake in disregarding the character, quality and location of its buildings which was made in so striking a manner by one of our American universities, a mistake which, in spite of the great men obtained by an otherwise most sagacious president, has led to a hampering of its development, and, in part at least, has been responsible for a threatening of arrest of some of its high functions.

Medical News.

ILLINOIS.

Intending Practitioners.—The State Board of Health, on April 15, 16 and 17, conducted an examination of 181 candidates to practice medicine in Illinois. Of these, 25 were women.

In Memoriam.—At the meeting of the Fox River Medical Association in Elgin, April 14, Dr. James W. Pettitt, Ottawa, delivered an eloquent address eulogistic of the late Dr. Edgar P. Cook of Mendota.

The medical practice act was passed by the senate April 15. The bill would divorce the board of medical examiners from the State Board of Health, which has hitherto held all examinations for physicians' licenses. The bill is not yet passed by the house.

Chicago.

Cook County Internes.—The result of the examinations for interneships in Cook County Hospital was made known April 17. Rush Medical College secured 6 places; Northwestern University 7 places and the University of Illinois 3 places.

Personal.—Drs. Wellington T. and Harry J. Stewart have sailed for Europe.——Dr. John Kercher, in resisting a levy on his property, April 17, shot a constable, and is under bonds awaiting the outcome of the wound. After he had shot the man, learning that he was a constable, Dr. Kercher surrendered to him.

High Mortality.—With one exception the week's mortality is the highest of the year. During the week ended February 28 there were 713 deaths recorded, giving an annual death rate of 19.73 per thousand of population—the highest rate for any February week in the history of the department. Last week 640 deaths were recorded, and the annual rate was 17.69 per thousand. The principal causes of death were pneumonia, 135; consumption, 75; Bright's disease, 52; bronchitis, 39; heart disease, 36, and violence 37. There were 75 more deaths from diseases of the respiratory system and of the kidneys last week than during the week of April 4—an increase of exactly one-third.

Diminishing Deaths Among Young.—The Department of Health, despite the high death rate, finds consolation in the steadily diminishing number of deaths of infants and young children as follows:

> During the six years preceding the present administration of the department there had been 66,003 deaths of those under 5 years of age; during the six years of the present administration, 1896-1902, there have been only 51,046 such deaths, or 14,957 fewer than in the first period. But this tells only part of the story. The population of the city increased, according to the United States census, 3.4

per cent. per annum between 1890 and 1900, and it is fair to assume that the under-5-years population increased in at least the same ratio. It follows that if the death-rate of the earlier period had been continued during the last six years there would have been 87,387 under-5-years-of-age deaths instead of the 51,046 that did actually occur.

MARYLAND.

New Hospital Site.—The first site of Cambridge Hospital has been sold for $2,500, and a new site on a bluff commanding a view for miles of the Choptank River has been purchased. It is expected the new building will be ready for occupation by June 1, 1904.

Baltimore.

Deaths of the Week.—The number of deaths last week was 233 against 176 for the corresponding week last year, an annual death rate per 1,000 of 20.97. Consumption caused 43 deaths, pneumonia 31, Bright's disease 26, and typhoid fever 6.

Reception to Dr. Cordell.—A reception was tendered Dr. Cordell, April 21, by about 50 members of the Medical and Chirurgical Faculty, in commemoration of the completion and publication of the centennial volume, "The Medical Annals of Maryland," which has been in preparation for the past five years. Dr. Cordell gave a résumé of the work. It is a handsome illustrated volume of 900 pages.

Association of Endowed Medical Schools.—It is said that a proposition has been submitted by a representative of Chicago University to found an association of endowed university medical schools, somewhat on the plan suggested by Dr. Barker some time ago. A meeting has been called in Washington next month, but only about half a dozen of the leading schools have been invited. It is understood that Johns Hopkins University objects to this narrow limit.

Oppose Higher Standards.—Opposition is developing in the colleges to the proposed amendment to the regulations of the American Medical College Association raising the standard of preliminary requirements. The effect of this amendment, it is thought, will be to make the standard equivalent to graduation from a high school. At a recent meeting of representatives of the faculties, all present, except the delegate from the Johns Hopkins Medical School, voted to oppose it at the coming meeting at New Orleans.

Personal.—Dr. August F. Volkman celebrated his golden wedding, April 12.——Dr. Benjamin R. Schenck has resigned from the staff of the Johns Hopkins Hospital, and will enter on practice at Detroit, Mich. The vacancy will be filled by Dr. John A. Sampson.——Dr. L. Ernest Neale is in London.——Dr. B Bernard Browne has been seriously ill from an infected wound. He was operated on by Dr. Tiffany, and a mass of glands removed from his axilla.——Dr. John Stephenson, professor of anatomy at the University of Edinburgh, was in the city last week.——Dr. Herman Westphal has gone on a visit to Deer Lodge, Montana.——Dr. J. Clement Clark has resigned the chair of psychiatry at the Woman's Medical College.

MASSACHUSETTS.

Epidemic of Pertussis.—Boston is in the midst of a semi-epidemic of pertussis, especially that portion of the city known as Back Bay. Four deaths were reported last week.

Emergency Ward Opened.—The Visiting Nurse Association of Winchester has equipped a surgery for the treatment of accident cases and for slight surgical dressings, as a first step toward a hospital.

Addition to Hospital.—An addition to the Lynn Hospital, which will be two stories, 83 by 37 feet, to accommodate 17 patients on the lower floor and provide 12 private rooms on the upper floor, has been started.

Faculty Changes.—Harvard overseers have elected Dr. Edward H. Bradford professor of orthopedic surgery, Drs. Maurice H. Richardson, and Herbert L. Burrell professors of clinical surgery, and Dr. John H. McCollom, assistant professor of contagious diseases.

Boston Health.—The report of the board of health for the week ending April 18 shows an annual death rate of 19.57 per 1,000. There were 26 cases of diphtheria reported, with 6 deaths; 25 of scarlatina, with 1 death; 9 of typhoid fever, with 1 death; 28 of measles, with 3 deaths; 25 of tuberculosis, 22 deaths. Pneumonia caused 36 deaths, heart disease 16 and bronchitis 5 There were 76 deaths in public institutions.

Boston City Hospital.—Reports for the year ended Jan. 31, 1903, 8,462 patients treated, with 875 deaths. The daily average was 401 patients. There are 32,152 out-patients. The entire expense was $472,873.54. The south department (contagious) has been many times much crowded A measles ward is the great need there. The relief station in Haymarket square has been a great success. Here, for an expense of $34,-905.24 in the first 11 months, 19,064 out-patients were given first treatment, and 1086 were kept in the wards one or more days, and 765 ambulance calls were answered.

MICHIGAN.

Personal.—Dr. Albert A. Parisot has been elected mayor of Mount Clemens.

Memorials.—At the April 9 meeting of the Wayne County Medical Society, Detroit, suitable resolutions were passed regarding Drs. Peter Klein and Edward W. Jenks, deceased members.

New Medical Building Opened.—The new medical building at the University of Michigan, Ann Arbor, was formally dedicated, April 2, the opening address being made by Dr. Herman Kiefer, Detroit, the former regent.

Physician Assaulted.—Dr. Abram M. Crawford, an aged practitioner of Michigan Center, was assaulted by some person unknown, while sitting in his house, March 30. A deep scalp wound was made, and an artery severed. It is believed that Dr. Crawford will recover.

Most Dangerous Communicable Diseases.—Meningitis was reported in March at 7 places; whooping cough at 51 places; diphtheria at 62 places; typhoid fever at 62 places; measles at 120 places; scarlet fever at 147 places; smallpox at 169 places, and consumption at 189 places. Reports from all sources show meningitis reported present at 2 places less; whooping cough at 5 places more; diphtheria at 15 places less; typhoid fever at 27 places less; measles at 17 places more; scarlet fever at 52 places less; smallpox at 32 places less, and consumption at 4 places less in March than in the preceding month.

Comparative Morbidity.—For March, compared with the preceding month, intermittent fever and typhoid fever were more prevalent; and smallpox, erysipelas, inflammation of bowels and diphtheria were less prevalent For the same month, compared with the average for March in the 10 years, 1893-1902, scarlet fever, smallpox, whooping cough and typhoid fever were more than usually prevalent; and consumption, inflammation of kidney, intermittent fever, erysipelas, inflammation of bowels, and remittent fever were less than usually prevalent. The diseases which usually cause the most sickness in Michigan at this time of the year were slightly less prevalent than usual in the March just passed. This lessened prevalence was apparently due to the higher temperature, and the lessened amount of ozone during the month.

March Mortality of Michigan.—The total number of deaths reported for March was 3,034, or an increase of 278 over the preceding month. The death-rate, however, was exactly the same as for the preceding month, 14.4 per 1000 population. The mortality was slightly higher than for March, 1902. Important causes of death were as follows: Tuberculosis, 237; typhoid fever, 48; diphtheria, 34; scarlet fever, 22; measles, 29; whooping cough, 34; pneumonia, 403; diarrheal diseases, under 2 years, 51; influenza, 140; cancer, 143, and accidents and violence, 150. Comparing March with the preceding month, there was an increase of mortality from all the causes stated above, with the exception of diphtheria, which disease showed considerable decrease The mortality from influenza was nearly double that of the preceding month. The death rate was slightly higher than for March, 1902. There were 3 deaths reported from smallpox during the month, while 5 deaths were returned from this cause for February.

NEW YORK.

Medical Bequests.—The will of the late county judge, Hon. Henry T. Nason of Troy, devises $10,000 to Dr. E. D. Ferguson, in case of the predecease of his mother, and $25,000 in the event of the predecease of his mother and grandfather, and to the Samaritan Hospital, at the decease of his mother $10,000, and an additional amount which will bring the entire bequest up to about $80,000.

Elsberg Bill Killed.—It is alleged that because Senator Elsberg acted independently from the machine in state politics and as a matter of petty spite work and revenge, the machine has killed his bill for the abolition of coroners for Greater New York. The machine Republicans in the senate have disreguided the earnest demands of the citizens of Greater New York, and it is only a question of time when the bill must pass

Opposition to Site for Tuberculosis Hospital—Attorney General Cunneen has been asked to institute proceedings to prevent the establishment of the State Hospital for Tuberculosis Raybrook, on the plea that it was highly objectionable to certain summer residents in the vicinity Mr Cunneen refused to bring such suit, and at about the same time the senate finance committee reported favorably on the appropriation of $115,000 for the support of the hospital at Raybrook

New York City.

Without License.—Nicola D'Amato, an Italian of Brooklyn, was arrested April 6, on the charge of practicing medicine without a license from the board of health The warrant was issued by the registrar of vital statistics

Loomis Lectures on Sanatoria—Dr Henry P Loomis delivered a popular lecture in the United Charities Building on Sanatoria and Climatic Influences in the Prevention of Tuberculosis ' illustrating it with stereopticon views of the leading sanatoria

Thousands for Gouverneur—At the request of the president of the Board of Trustees of the Bellevue and Allied Hospitals, the issue of $125,000 corporate stock for the purpose of completing the construction of Gouverneur Hospital was granted by the board of estimate

Mikulicz in New York—Prof von Mikulicz is in the city as the guest of Dr Fred Kammerer A dinner was given by Dr Kammerer in his honor, and an opportunity was thus afforded of presenting the distinguished foreign surgeon to a number of eminent members of the local profession

Work of Throat Hospital—The Metropolitan Throat Hospital, during a period of thirty years, has been the means of affording free medical assistance to a large class among the deserving poor of New York According to its recently issued report, 27,244 individuals have been received since its foundation, and a total of more than 218,364 visits have been made to its dispensary During the last year, 1,307 patients were treated in the clinics

Garnault Here.—Dr Paul Garnault, the Paris physician who, in June 1901, offered himself for experimentation in order to refute Koch's assertion that tuberculosis can not be transmitted from cattle to man, is now in New York His object in coming here is to deliver a series of lectures on the evolution of Roman Catholicism Speaking of the inoculation experiments made on him by three other physicians, and at the same time, as a control, on guinea pigs, he stated that in 25 days the guinea pigs developed tuberculosis, and died within two months, and that when examined in July by Dr Roux, that savant declared that a local tuberculosis had been set up in Dr Garnault That the process did not become general is attributed to his vigorous health

Buffalo.

Personal—Dr Charles G Stockton is in California ——Dr Charles Cary will spend several months in Europe ——Dr Augustus Pohlman has resumed his work as instructor in anatomy at Cornell University

March Mortality.—The monthly report of the department of health for March shows a death rate of 15 91 per 1,000 The principal causes of death were as follows Pulmonary consumption, 45, cerebrospinal fever, 4, diphtheria, 7, pertussis, 14, typhoid fever, 11, debility, 45, cancer, 24, apoplexy, 18, meningitis, 24, valvular heart disease, 28, pneumonia, 55, appendicitis, 7 cirrhosis of liver, 7, chronic nephritis, 12, and violence, '36 Total deaths 504, as compared to 520 in March, 1902

PENNSYLVANIA.

Car Quarantined.—Smallpox on a Pullman car on an Erie train caused the car to be detached at Meadville and quarantined The passengers were vaccinated

The Typhoid Epidemic at South Bethlehem—About 200 cases of typhoid fever have occurred during the winter at South Bethlehem The epidemic is ascribed to impure drinking water It has been proposed to place a filter in the Lehigh river, but a report on the proposed method, recently made by an expert, expressed disbelief in the filter proposed, and recommended the slow process of sand filtration as the only effective means of purification

Additional Appropriations—In addition to the appropriations to hospitals already mentioned in THE JOURNAL the following appropriations were finally passed by the legislature: Home for the Friendless, $6,000, Temporary Home for the Aged, $3,000; Woods Run Industrial Home, $1,500, all of Allegheny, Home for the Aged, $4,000, Hayes Mechanics' Home, $3,000, German Hospital, $30,000, Orthopedic Hospital $31,000, all of Philadelphia, Corry Hospital, $7,000, Wilkesbarre Hospital, $38,000, and Hamot Hospital, $16,000

Compulsory Report of Communicable Diseases.—A bill was passed by the legislature, and now awaits disposition by the governor, making it a misdemeanor for any physician or other person knowingly not to report, within ten hours, a case of smallpox, diphtheria, or scarlet fever, which may come to his knowledge, providing a fine of from $50 to $500, or imprisonment from ten days to six months, or both, and also making it compulsory on all cities, boroughs and townships to furnish quarantined persons medical aid, necessaries of life, etc

Hospital for Feeble-Minded—Among other bills in the hands of the governor, is one appropriating $50,000 for the selection of a site and the erection of a state institution for the feeble minded and epileptic, to be called "The Eastern Pennsylvania State Institution for the Feeble Minded and Epileptic," and also a bill making it the duty of school directors, trustees or other persons having control of any school or college building, to adopt and immediately to put into operation a modern method and system of disinfection for school or college buildings

To Suppress Smallpox.—The sum of $50,000 asked for by the state board of health has been appropriated by the legislature The amount is largely to be used in the suppression of smallpox Dr Wilmer R Batt, quarantine officer at large, and his assistants, are at work in counties west of the Alleghenies, where the disease is epidemic, establishing quarantine, enforcing vaccination and other measures for stamping it out There are many centers of infection, in Tyler, Clearfield County, about 50 cases of smallpox were found, and no precautions had been taken to prevent the spread, the disease was found in about half a dozen villages, of which Houtzdale was the center, the whole district has been, for the present, quarantined The disease is also prevalent east of the Alleghenies, in Lycoming, Bradford and Susquehanna Counties, where active preventive measures are being instituted In Philadelphia and vicinity the disease is decreasing

An Oil City Feast.—On April 15 the medical profession of Oil City gave a banquet in honor of Dr Miles F Porter, Fort Wayne, Ind, at which Drs Roswell Park, Matthew D Mann and Charles G Stockton, Buffalo, N Y, were guests of honor Dr Clarence W Coulter was toastmaster, and Dr John A Ritchey delivered the address of welcome The following toasts were responded to "What's the Use," Dr Miles F Porter, "The Irregular Physician," Dr William A Nicholson, Franklin, Pa, "Let Us Not Forget the Lessons of Past Years," Dr Roswell Park, "The Regular Physician," Dr John C O'Day, Oil City, 'Early Reminiscences of Gynecology," Dr Matthew D Mann, and "Status Presens," Dr Charles G Stockton Dr Roswell Park touched on the sad condition of affairs existing between New York and the National body, the American Medical Association He expressed the earnest hope of seeing the difficulty completely removed and to see his own state harmoniously in line with the rest Dr Miles F Porter said that, as a member and director of the association, he would do his mite toward effecting this end

Philadelphia.

Public Health and Charities—As authorized by act of the legislature, the city councils have created the new department of Public Health and Charities It is stated on good authority that Dr John V Shoemaker will be director of the new department

Pre-Nuptial Banquet—On the evening of April 18 Dr James M Anders was given a dinner by his brother members of the faculty of the Medico Chirurgical Medical College The toasts, several in number, were with reference to the approaching marriage of Dr Anders

Poisoner Indicted.—Mrs Catherine Danz has been indicted by the grand jury for the murder of her husband by the administration of poison, and George B Hossey, the negro 'herb doctor, was also indicted as an accessory to the crime, for furnishing the poison Expert analysis of portions of Danz's body showed the presence of both arsenic and antimony

Communicable Diseases—A decrease has occurred in the number of new cases of typhoid fever and smallpox, but an increase in diphtheria and scarlet fever. For the week ended April 18, there were, of typhoid fever, 160 new cases, as compared with 204 for the previous week; of smallpox, 10, as compared with 16 the previous week; of diphtheria, 78, as compared with 59 the previous week, and of scarlet fever 89, as compared with 70 the week before. There are under treatment in the Municipal Hospital 72 cases of diphtheria, 134 of scarlet fever, and 70 of smallpox. Nearly all the blame for the epidemic of typhoid fever may be ascribed to bad water. Of the 204 cases occurring during the week ended April 11, 67 were in a portion of West Philadelphia, where the residents receive most of the water supply by direct pumpage from the Schuylkill river.

GENERAL.

End of the Mazatlan Plague.—The city of Mazatlan, Mexico, has had no new cases of plague for some time and business has resumed its usual aspect.

Mikulicz Visits America.—Prof. J. Mikulicz, the famous Breslau surgeon, is visiting America. It is hoped that he will attend the New Orleans session.

Marine Hospital at Nome.—The United States Public Health and Marine-Hospital Service has established a hospital at Cape Nome, Alaska, and the hospital at Dutch Harbor will be discontinued.

Disinfection of Mail.—The postoffice department has issued a general order calling attention to the regulations governing the disinfection of mail matter, because of the prevalence of smallpox and other diseases in certain portions of the country.

Constabulary Medical Corps.—The Philippine Commission has provided for the appointment of three surgeons to the Insular Constabulary, and Drs. Winslow, Wheate and Baker have been appointed. They were formerly captains and surgeons of volunteers, and Dr. Winslow was prominent in the fight against cholera last year.

Recuperation Hospital in Philippines.—General Davis, U. S. A., commanding the Division of the Philippines, has arranged to have a large modern hospital erected near Mariveles at a level of about 3,000 feet. The special object is to provide a place where officers and men who are suffering from the effects of tropical climate may recuperate.

Personal.—Dr. H. C. Sloggett, Honolulu, founder of the Honolulu Eye and Ear Infirmary, former president of the Hawaiian Territorial Medical Association and former president of the Hawaiian Territorial Board of Health, has sailed for Shanghai, China, to become general manager and medical director of the Oriental Life Insurance Company.

Window Memorial for Physician.—A handsome memorial window has been placed in the Center church, Hartford, Conn., in memory of Dr. Horace Wells. The inscription credits him with being the discoverer of anesthesia. The service in the church in connection with the window was attended by the Hartford Medical Society and the Hartford Dental Society and by many physicians and dentists from other cities

The Army Medical School closed its sixth session April 14. The exercises were held in the hall of the National Museum. An address was delivered by John S. Billings, M.D, LL.D., deputy surgeon-general, retired. The diplomas were presented by the Hon. Elihu Root, secretary of war, and the Hoff memorial medal was presented by Gen. William H. Carter, U. S. A., of the War College board, to Assistant-Surgeon Harry L. Gilchrist for the highest average. This is the largest class graduated since the school was founded, in 1893, there being 38 graduates. Of this number the following were honor graduates, having an average of more than 90 per cent.: Harry L. Gilchrist, Samuel M. Deloffre, John W. Hanner and Edward M. Talbott. Most of these young medical officers have already been ordered to the Philippine Islands for duty The following first lieutenants and assistant surgeons were the other graduates:

George H. R. Gosman, Reynold M. Kirby-Smith, William H. Moncrief, George L. Collins, Nelson Gapen, William T. Davis, Charles F. Morse, Samuel E. Lambert, Haywood S. Hansell, Junius C. Gregory, Jay W. Grissinger, Will L. Pyles, Thomas Devereux, William M. Smart, Robert H. Pierson, Cary A. Snoddy, Harry S. Purnell, Robert M. Blanchard, James Bourke, Louis C. Duncan, John A. Clark, Samuel J. Morris, Noel I. Barron, Jacob M. Coffin, Levy M. Hathaway, Alexander Murray, Philip W. Huntington, James D. Fife, William A. Powell, Leon T. LeWald, Jesse R. Harris, George H. Scott, Edwin D. Kilbourne, Robert L. Carswell.

U. S. Regional Death Summary.—The death map prepared by the Census Bureau shows some interesting facts as to the geographical distribution of diseases. For example, affections of the lungs are most common along the Atlantic coast from New York to Virginia and along the Mississippi River from Missouri to the Gulf. Typhoid fever and malaria are naturally rare in mountainous districts, but are at the head of the list in North and South Carolina, Georgia, Alabama, Mississippi, Arkansas and Indian Territory. Sensational deaths occur most frequently on the Pacific Coast. In the state of Washington gunshot wounds are a prevalent cause of death. On the Pacific Coast heart disease, suicide, apoplexy and alcoholism claim more victims than in other sections of the country. A general statement is made that three out of every 100 die of old age, but in a few districts old age is almost as important a cause of death as consumption or malaria. These places are the Catskills, Adirondacks, Green Mountain, parts of Michigan and Wisconsin and the region bordering on the Missouri River. In mountainous districts, cancer, heart disease and apoplexy are more common than on level ground. Croup and whooping cough appear to be most dangerous in the most thinly-settled districts As a general proposition, most deaths in the country are caused by climatic conditions, while those in cities are largely caused by social conditions. The map makes an interesting study for the physician.

FOREIGN.

Lannelongue Endowment at the Paris Academie des Sciences.—Professor Lannelongue has presented a fund to the Académie representing an annual income of $240.

French Hygienic Mission.—Dr. F. Gallard of Paris has been sent to this country by the minister of commerce and industry to study the hygiene of the working classes in the manufacturing centers here, from the double point of view of the professional environment and administrative assistance, that is, medical and hospital aid.

Agricultural School for Nervous Children.—Dr. Strohmayer, a prominent neurologist at Jena is director of an educational institution recently opened there for nervous and feeble-minded children. The raising of fruit, flowers and vegetables and forestry will be taught both theoretically and practically by teachers trained for the task.

Defective Acoustics in the New Paris Academie de Medicine.—The committee on remedying the defective acoustic properties of the new hall, recommend carpeting the hall, stretching threads across under the glass ceiling, substituting thinner panes of glass when any are broken, hanging tapestry or curtains along the walls and behind the platform, and curtaining off the boxes.

An Experiment in Switzerland.—The "Gazette Med. de Paris" states that Zurich is now debating a scheme to establish medical guardians of the public health. It is proposed to tax every individual over 18 at the rate of 80 cents a year. This will supply a sum sufficient to retain the services of forty physicians, who will watch over the maintenance of the health of the populace.

Milk Exposition at Hamburg.—In connection with the approaching Milk Exposition at Hamburg several works have been published dealing with the care of milk from various standpoints. The largest is entitled "Die Allgemeine Milchkunde," and contains everything known to date on the subject of milk and milk hygiene for the use of families, milk dealers, farmers, physicians and others.

Medical Censorship of Charlatans' Ads.—A German publishing house, A. Scherl, has officially applied to the German Medical Press Association with the request that it would pass judgment in dubious cases on the advertisements of applicants, whether they should be rejected as quack ads or not The association unanimously resolved to accept the proffered control and place their services at the command of the firm in the matter.

Prizes Awarded from the Pettenkofer Endowment.—A diploma and prize of $190 has been awarded by the committee in charge of this fund at Munich to three scientists. The first is Dr. Karl Flügge, director of the Institute of Hygiene at Breslau, as a token of appreciation of his works on formaldehyd disinfection and the transmission of phthisis by droplets expelled in sneezing, coughing and speaking. The second recipient is Dr. Dunbar, director of the similar institute at Hamburg, for his research on the so-called biologic cleansing process. The third is Dr. Ohlmüller of Berlin for his method of ozone purification of water.

Anti-Alcohol Congress.—The International Anti-Alcohol Congress opened in Bremen April 15. Secretary von Posadowsky-Wehner, in his opening address, said that the increased strain due to the advance of civilization encourages the use of stimulants. Legislation is not the real remedy for the abuse of alcohol. Education of the people to a higher sense of morality is the remedy. Dr. Delbrueck, Bremen, was elected president. Professor Legrain of Paris, speaking on "Alcoholism and Tuberculosis," said that the use of alcohol predisposes the human system to tuberculosis, and also prevents the cure of it. Alcoholism intensifies the effect of diseases which create those conditions which are best fitted for the ravages of tuberculosis. Since the triumph over alcoholism, he continued, is approximately a triumph over tuberculosis, the real, individual and social treatment for tuberculosis consists in the strictest abstinence from alcoholic liquors. A lively discussion ensued.

The Battle of the Clubs.—The sick benefit societies at Stralsund surprised their medical officers, who had just resigned in a body, by granting their modest demands, and peace reigns once more. The physicians connected with the Mülhausen Kassen have recently asked for an increase of 16 per cent. over the present rates of 50 cents per capita and $1.50 per family. As the request was refused, they have all resigned. No change has occurred in the state of affairs at Gera, but our German exchanges still bear the display ad: "Physicians, do not go to Gera. Colleagues who are thinking of treating with the Textile Industries Kassen at Gera are requested to apply to Dr. Schrader, Gera, Reuss, or to Dr. Hartmann of Leipsic-Connewitz, president of the Leipziger Wirthschaftlicher Verband." The Verband mentioned is the "Union for Promoting the Material or Economic Interests of Physicians in Germany," to which we have often referred. It is stanchly supporting the physicians in their position. The Gera resignations were on purely ethical grounds, refusal to co-operate with a "nature healer" as a member of the medical staff on the same terms as the rest.

LONDON LETTER.

The Polyclinic.

The annual meeting was held on March 31. Sir W. Broadbent, the president, pointed out the gratifying progress of the institution, the number of members having risen from 825 in 1901 to 941 at present. A composite course of lectures on medicine and surgery has been organized and on payment of a fee of $5 a member may attend these lectures, one of which is delivered daily. The fee for non-members is $10. Many valuable additions have been made to the Hutchinson Museum and the whole collection has been so classified and arranged as to permit of speedy and easy reference. A companion catalogue has been published in the "Polyclinic." The financial report of the institution is not so satisfactory: the balance sheet for the year shows a deficiency of $2,000. The annual subscription of members ($5) and the fees charged for tutorial classes are not sufficient to meet the working expenses, and appeals to the charitable public for support have not been as successful as was hoped. They regard the institution as a doctor's affair and think it should be supported by the profession. As no hospital is attached, it does not appeal to their imagination. Sir W. Broadbent said that he never ceased to hope that, sooner or later, a properly equipped hospital would be acquired. A proposal was made to raise the annual subscription to $10.

Treatment of Trachoma by the X-Rays.

At the Ophthalmological Society Mr. M. S. Mayou, in describing this method, pointed out that with care the amount of reaction could be regulated. Even prolonged exposure of the globe to the *x*-rays was attended only by such trifling bad results as falling out of the lashes and conjunctivitis. Experiments on rabbits and frogs showed that the *x*-rays did not bleach the visual purple. The technic of the treatment consisted in everting the eyelids (the operator's hands being protected with bismuth ointment and cotton gloves), the cornea was exposed only when severe pannus was present. The infiltration set up caused difficulty in deciding when treatment should cease. The advantages of the treatment are: (1) less resultant deformity, (2) painlessness, (3) more thorough clearing of pannus.

Mr. Hutchinson on the Plague in India.

While engaged in his tour of investigation of leprosy in India, Mr. Hutchinson, as might have been expected, has found many subjects which have engaged the attention of his versatile intellect. Writing from the town of Amritzur, in which in the past week 731 persons had died out of 1,076 suffering from plague, he comments on the remarkable absence of anything like panic in the cities of India. In Lahore, the city which he had just left, the mortality was 390 out of 833 cases. The little town of Taran-tara, with a population of 4,000, a resort of pilgrims, he found comparatively deserted, its narrow streets closed and marked with a long bar of white paint, showing that deaths from plague had occurred in them. In many instances whole families had been carried off; the mortality was 95 per cent. Yet business was going on as usual, and a long string of pilgrims on foot, in carriages, or mounted on camels was passing through its narrow streets. The procession was miles in length, and had very properly been forbidden by the government, but the authorities were not strong enough to prevent it The natives are absolutely careless as to precautions, though willing enough to run out of a house in which the disease occurs. Mr. Hutchinson fears that the disease will soon have established itself over the whole of India. Isolation is impossible. The natives will not permit removal of their relatives and often will not seek skilled advice. When several cases have occurred in a house they take alarm and desert the patients, leaving the burial and disinfection to be done by others, but they will give no assistance to measures of precaution. Their religious principles prevent them from killing rats or being in any way accessory to their death. They will catch them alive in traps, take them a distance and let them loose, not improbably in some one else's garden. In order to meet the prejudices of the natives rewards are offered for live rats, which are fed and housed. At Amritzur they are kept in a large room with a stone floor and fenced with wire and liberally fed. But the confinement and inability to burrow does not suit them and they soon die. The inhabitants of the district object to this "rats' hell" in their midst, and another site will have to be found. The physicians and other Europeans exposed to the plague have received prophylactic injections of serum. The results are painful, and a severe rigor, temperature of 104, and distressing lassitude follow. In the natives the reaction is less severe. Great confidence is placed by the physicians in the efficiency of the injections, as well as in the use of immunized blood serum in the treatment of the disease.

Tetanus After the Subcutaneous Injection of Plague Serum.

The natives require much persuasion to submit to prophylactic injections of serum, and the lamentable accident which occurred last November and which we have described (The Journal, January 31), was eagerly published by the native press and did much to confirm their prejudices. The following are additional particulars: Nineteen healthy young natives were injected on the same occasion from a bottle of Haffkine's fluid All developed symptoms of acute tetanus on the fifth day, and died within a few days. Other bottles in the same consignment were innocuous. The operator was well skilled and careful and all the usual precautions were observed. In the district tetanus is common. Hence contamination probably took place on the spot. Perhaps it resulted from the syringe and not from the fluid.

Correspondence.

The Mosquito as a Carrier of Disease.

Vera Cruz, Mexico, April 12, 1903.

To the Editor:—In The Journal, April 4, appears an article by Dr J. Stebbins King on "The Mosquito as a Carrier of Disease." In this article Dr. King makes the following statements:

1. . . . Hundreds of non-immunes are bitten every year by infected culex mosquitoes where yellow fever exists as an epidemic and do not take the disease."

2. . . . Non-immunes can be exposed for days and months to yellow fever, and that, too, in the presence of infected culex mosquitoes, and not take the disease. . . .

3. The Doctor does not so state, but implies, that the mosquito is not the only means of transmitting yellow fever.

4. The writer, . . . can most positively vouch for the truth of every statement here made [in his article].

In reply to these four statements, it is well to mention the fact that it is impossible to prove whether a mosquito is infected with yellow fever or not without trying to inoculate a non-immune with the suspected insect. No microscopic or bacteriologic examination is of the least value, as nothing has been found in the infected insects that is of the least diagnostic importance. Unless the Doctor had control of the mosquitoes and tried them out on the non-immunes he can hardly vouch for the truth of his first statement.

In regard to his *second statement*, *it* is absolutely false, so far as the non-immunes being exposed to infected culex mosquitoes. Drs. Reed, Carroll and Agramonte demonstrated beyond a doubt that infected mosquitoes would infect non-immunes, and the same thing has been further demonstrated here in Vera Cruz. If there are any non-immune doubters that have to be shown this fact and have an infected insect feed on them, they can be accommodated at any time. The reason why non-immunes can be in constant attendance on yellow fever patients and not contract the disease is only explained by the mosquito transmission theory. The mosquito can not transmit the disease until ten or twelve days after biting the infected patient. In that time the patient is convalescent, the *room disinfected* and aired and, in all probability, the infected insects killed or driven over to the neighbor's house.

It is very probable also that the patient is covered with a mosquito bar and the nurse, through human instinct, *exterminates* all *mosquitoes in sight*.

As to the third statement, the Doctor only implies that there is some other means of carrying the infection, yet does *not* advance either a fact or theory as to the means. I have seen yellow fever produced by the mosquito inoculation and also by the injection of blood from a person suffering from the disease into a non-immune. I have seen yellow fever fail to develop in three non-immunes who were confined in a mosquito-proof room with a man suffering from a severe case of yellow fever, and who remained in the room throughout a period of four weeks. I have had numerous cases during the past year in which non-immunes nursed yellow fever cases and did not contract the disease, and the *only precaution taken* was to screen the room and keep the patient under a good mosquito net I had one case in which a mother nursed a 2-months-old baby during the first four days of her attack of yellow fever—and only ceased because the secretion of milk stopped—the child staying in the bed with its mother *throughout the whole* course of the disease, yet did not contract yellow fever, the room being entirely free from mosquitoes. The experiment was tried here of giving to a non-immune, whose stomach had been previously emptied, twenty-three infected mosquitoes in a capsule, without any effect whatever.

The complete extermination of the fever in Havana through the destruction of the stegomyia should carry some weight with the thinkers, and such an article as that written by Dr. King can only cause doubt in the minds of men who are not acquainted with the facts in the case.

If Dr. King or anybody else has any theory, fact or suggestion as to any other means of transmitting yellow fever, they will confer a favor by making it known, as there are many men in yellow fever communities and elsewhere who would gladly demonstrate the truthfulness of such a theory or suggestion. The Mexican government, the Marine-Hospital Service and the state boards of Alabama, Louisiana and Texas have accepted as proven the mosquito transmission theory, and their quarantine laws are based on this fact.

Let those who doubt refrain from publishing assertions until they can prove one little fact about their other means of propagating the disease, for such articles only produce doubt in the minds of those living within the infectible territory of the United States, and cast reflections on the work of the best men in charge of our quarantine system.

Samuel H. Hodgson, M.D.,
Acting Assistant Surgeon, U. S. Marine-Hospital and Public Health Service. Last six years residing and practicing in a yellow fever epidemic.

Typhoid Perforation Data Wanted.

Nashville, Tenn., April 17, 1903.

To the Editor:—I desire to request any surgeon who has operated for intestinal perforation or peritonitis in typhoid fever, to send me the data of the cases and reference, if they have been published, under the following heads: Age. Sex. Severity of the fever. Symptoms of perforation. Abdominal signs. Date of disease when perforation occurs. Length of time after perforation before operation. Leucocytosis (if any tests). Description of findings at operation. Site of perforation. Result. Remarks.

I have collected 261 cases in the literature, and feel sure that many more have remained unfound or unreported. For the purpose of a complete statistical investigation of this important surgical problem, I respectfully request the above reports at as early a date as possible.

W. D. Haggard

Marriages.

T. E. McMurtrey, M.D., to Miss Grace Polglase, both of Chicago, April 15.

Herman D. Peterson, M.D., to Miss Marie Freeman, both of Chicago, April 20.

Leighton P. Allen, M.D., to Miss Frances Ideson, both of Oshkosh, Wis., April 15

Daniel W. Rogers, M.D., Chicago, to Miss Helen S. Wainwright, at Chicago, April 14.

James Lang Lewis, M.D., Lawton, Okla., to Miss Elizabeth Shaw of Chicago, at Joliet, Ill., April 21.

Guy B. Van Zandt, M.D., Montrose, Ill., to Miss Lucille Cuddy of Allan Reed, Texas, at St. Louis, Mo., April 9.

Deaths.

Isaac W. Fink, M.D. St. Louis Medical College, 1854, a member of the American Medical Association, Mississippi Valley Medical Association, Illinois State Medical Society, Central Illinois Medical Society and for several years president of the Montgomery County Medical Society, died at his home in Hillsboro, Ill., April 14, from paralysis, after an illness of seven months, aged 78.

Edmund Ludlow, M.D. Northwestern University Medical School, Chicago, 1895, formerly interne at St. Luke's Hospital, Chicago, and at the Central Indiana Hospital for the Insane, Indianapolis, who left his home in Paxton, Ill., in search of health, going first to Silverton, Colo., and then to Los Angeles, died in the latter city, April 5.

William S. Whitwell, M.D. Harvard University Medical School, Boston, 1872, of New York City, a member of the American Medical Association, died at the Riverview Sanitarium, Fishkill Landing, of which he was proprietor, from Bright's disease, April 8, aged 57.

Hugo Lupinski, M.D. University of Michigan, Ann Arbor, 1882, a member of the American Medical Association, for several years health officer of Grand Rapids, Mich., died at his home in that city, April 7, after an illness of two weeks, aged 44.

George W. Westlake, M.D. Medical College of Ohio, Cincinnati, 1866, a member of the American Medical Association, coroner and public administrator of Tehama County, Cal., died suddenly from heart disease in his office at Red Bluff, April 4, aged 59.

William M. Carothers, M.D. University of Pennsylvania, Philadelphia, 1890, of Braddock, Pa., died, April 12, at the Western Pennsylvania Hospital, Dixmont, from organic disease of the heart after a prolonged illness, aged 45.

Isaac S. Tanner, M.D. New York University, 1845, a surgeon in the Confederate service during the Civil War, and a resident of Shepherdstown, W. V., for more than half a century, died at his home, April 9, from paralysis, aged 85.

Bernard Stuve, M.D. Ohio Medical College, Cincinnati, 1851, who retired from practice in 1868 to practice law, died at his home in Springfield, Ill., April 11, from disease of the stomach, after an illness of a year, aged 73.

Gustave E. Sussdorff, M.D. Long Island College Hospital, Brooklyn, N. Y., 1866, of San Francisco, died at St. Mary's Hospital in that city from pneumonia, April 4, after an illness of one day, aged 60.

Hobart Cheesman, M.D. New York University, 1878, for the last twenty years one of the chief examiners of the Equitable Life Assurance Society, died at St. Luke's Hospital, New York, April 11, aged 58.

H. N. Coomer, M.D., of Ashley, Ohio, who had practiced for more than forty years in that locality, and had been for seven years past health officer of Ashley, died, after a long illness, April 1, aged 70.

Samuel P. Timmons, M.D. University of Louisville, 1896, who was compelled to move from Louisville to Texas a year ago on account of failing health, died at Graham, Texas, April 6, aged 38.

William A. Durrie, M.D. Yale Medical School, New Haven, Conn., 1846, of East Orange, N. J, who retired from active practice in 1884, died at his home, April 8, after a short illness, aged 81.

H. Cushman, M.D., of Stromburg, Neb., a member of the American Medical Association, died at his home, April 8, from pneumonia, after an illness of four days, aged 65

L. Gideon Archambault, M.D. Ecole de Medecine et de Chirurgie, Montreal, P. Q., 1869, died at his home in Woonsocket, R. I., April 8, from diabetes, after a long illness.

Guy Bryan Miller, M.D. College of Physicians and Surgeons, New York, 1898, formerly house physician at St. Luke's Hospital, died in Paris, France, April 7, aged 30.

George M. Silvers, M.D. College of Physicians and Surgeons, New York, 1878, died at his home in Chicago, April 15, from pneumonia, after a brief illness, aged 43.

Chauncey Ayres, M.D. Yale Medical School, New Haven, 1831, the oldest alumnus of that institution, died at his home in Stamford, Conn., April 14, aged 95.

Henry D. Kerfoot, M.D. Bellevue Hospital Medical College, New York, 1870, died at his home in Berryville, Va., April 9, after a protracted illness, aged 57.

J. C. Stone, M.D. Georgia College of Eclectic Medicine and Surgery, Atlanta, 1890, of Madison, Ga., died in a sanatorium at Atlanta, March 30, aged 38.

James D. Craig, M.D. Hygeio-Therapeutic College, New York, 1858, died at his home in Rogers Park, Chicago, April 13, from pneumonia, aged 70.

John A. Evans, M.D. Missouri Medical College, St. Louis, 1882, died at his home in High Hill, Mo., April 8, from disease of the stomach, aged 41.

T. W. Keith, M.D. Memphis, 1902, died at his home in Downing, Texas, from pneumonia, April 14, after an illness of six days, aged 36.

William H. Curry, M.D. University of Maryland, Baltimore, 1866, died suddenly at Baltimore, April 10, from heart disease, aged 61.

Thomas S. Jones, M.D. University of Pennsylvania, Philadelphia, 1868, died recently at his home in Shelbyville, Ind., aged 60.

Joel J. Walker, M.D. Louisville Medical College, 1878, died at his home in Hot Springs, Ark., April 9, after a prolonged illness.

Anna T. Mills, M.D. Woman's Medical College, Chicago, 1882, died from pneumonia at her home in Vinita, I. T., March 16.

Hugh Marshall, M.D. Rush Medical College, Chicago, 1852, died at his home in Monmouth, Ill., April 11, aged 77.

Charles A. Wunsch, M.D. Cleveland Medical College, 1867, died at his home in Saranac, Mich., April 8, aged 77.

James M. Tomlinson, M.D., Paris, France, died at his home in Indianapolis, April 9, from apoplexy, aged 81.

L. M. Bray, M.D., Toone, Tenn., died suddenly from apoplexy at his home, April 11, aged 75.

N. P. Givens, M.D., of Bowie, Texas, died April 5, aged 60.

Deaths Abroad.

Thomas Maclagan, M.D., who died recently, was, like many men who had attained eminence in the practice of medicine in England, a Scotchman. Though not on the staff of any hospital and, therefore, not a consultant in the ordinary sense, he had a very high-class practice. One of his patients was Thomas Carlyle. His success depended entirely on his sterling qualities. According to Sir F. Treves, "He was one of the most successful practitioners in London. He knew his work; he was one of the kindest and most sympathetic of men; he was rigidly upright and punctiliously honest." His salicylate treatment of rheumatism first brought him into prominence with his professional brethren. As long ago as 1876 he wrote what is curiously in accord with the most recent pathology: "Rheumatic fever is regarded as being produced by some cause or agency generated within the body. My investigations have led me to reject this view and to adopt the old 'miasmatic' view, according to which the cause is introduced from without." As the cinchonaceæ grow plentifully in malarious regions, he argued that possibly some plant which grew plentifully in regions where the rheumatic miasm prevailed would prove effective, and was led to try the salicaceæ. Decoction of willow-bark had been known as a cure for rheumatism long before, but in modern times Dr. Maclagan was the first to point out the value of salicin, which later was supplanted by the salicylates.——**Luciano Armanni, M.D.** University of Naples, 1861, professor of pathologic histology in the University of Naples, founder and director of the institute of pathologic anatomy connected with the Hospital for Incurables, died, after a long and painful illness, from disease of the lungs, March 15, aged 64.——**Emma Constance Stone-Jones, L. S. A.**, London, 1889; M.D. and Ch.M., Trinity College, Toronto, died recently at her home in Melbourne, Australia, aged 46.——**B. Von Kahlden**, professor of pathologic anatomy at Freiburg, died recently from apoplexy.

Book Notices.

The Diseases of Warm Countries. A Handbook for Medical Men. By Dr. B. Scheube, State Physician and Sanitary Adviser, Greiz. Translated from the German by Pauline Falcke, with Addenda on Yellow Fever, by James Cantlie, M.B., F.R.C.S.; and on Malaria, by C. W. Daniels, M.B., M.R.C.S. Edited by James Cantlie, M.A., M.B., F.R.C.S., D.P.H., Lecturer at the London School of Tropical Medicine. With All the Original Colored Maps, Charts, Illustrations, Etc., Together with Many Additional Plates, from the *Journal of Tropical Medicine*. Second Edition, Revised. Cloth. Pp. 594. Price, $8.00 net. Philadelphia: P. Blakiston's Son & Co. 1903.

This translation of Scheube's work is a valuable accession to the medical literature of the English language. It has had but one predecessor on the subject, and that is the comparatively small work by Manson. This is decidedly the more valuable work. Of course, the text is a little behind the times, but that has, to a certain extent, been made up by the addenda to the chapters on some subjects and in which a brief summary of the chief recent advances in our knowledge of malaria and yellow fever is given. A specially valuable feature of the work is its bibliographies, which brings the literature up to within a comparatively few years. It would have been better had the book been revised and annotated instead of merely translated, and we hope that in future editions this will be done. With a thoroughly detailed editing we know of no work that would be its superior and but few that are to be compared with it on its special subjects.. The translation has been well done.

Diseases of Women. A Clinical Guide to Their Diagnosis and Treatment. By George Ernest Herman, M.B. Lond., F.R.C.P., Obstetric Physician to and Lecturer on Midwifery at the London Hospital. With Upwards of 250 Illustrations. Revised Edition. Cloth. Pp. 884. Price, $5.00 net. New York: Wm. Wood & Co. 1903.

The object of the present volume, the author says, is to furnish a convenient manual for the student and practitioner and not a manual of reference for the specialist. It seems to us that Dr. Herman has succeeded very well in his purpose. He says he thinks he has one qualification for writing such a book, viz., clinical experience. That is certainly an important qualification. While the book is not strictly original in its treatment of the subject, it seems to be the result of good observation and, as might be expected from the preface, is not overloaded with references to the literature or quotations from other authorities. There is nothing specially novel in its classification. The illustrations are schematic, but generally excellent for the purpose; we believe that schematic illustrations are, as a whole, better for the student than the elaborate attempts at reproducing actual conditions and anatomic structures. There is not the reference to American authors and their work that one would look for, and some valuable contributions to gynecologic technic, etc., by American authors is not mentioned.

Harrington's Hygiene. A Manual of Practical Hygiene for Students, Physicians and Health Officers. By Charles Harrington, M.D., Assistant Professor of Hygiene in the Medical School of Harvard University. Second Edition. Revised and Enlarged. With 113 Engravings and 12 Full-Page Plates in Colors and Monochrome. Cloth. Pp. 755. Price, $4.25 net. Philadelphia and New York: Lea Brothers & Co.

It is not long since we noticed the first edition of this work. The second appears with some valuable additions and a general revision The principal additional matter is a chapter on the relation of insects to human diseases, a subject which has come very much to the fore within the last few years. The author's statements on the harmlessness of liqueurs or cordials, with the exception of absinthe, is not in accord with the latest French pronouncement on the subject, which, we think, must be based on as full testimony and study as any that the author has given to it. Aside from their alcoholic content, if we are not mistaken, liqueurs are declared by French authority to be decidedly harmful in themselves. Taken as a whole the book, we think, will maintain the popularity the former edition has received.

The American Year-Book of Medicine and Surgery for 1903. A Yearly Digest of Scientific Progress and Authoritative Opinions in All Branches of Medicine and Surgery, Drawn from Journals, Monographs, and Text-Books of the Leading American and Foreign Authors and Investigators. Arranged, with Critical Editorial Comments, by Eminent American Specialists. Under the Editorial Charge of George M. Gould, A.M., M.D. In Two Volumes. Volume I, Medicine. Volume II, General Surgery. Cloth. Price, per volume, $3.00 *net*. Pp. 691 and 670 Respectively. Fully Illustrated. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

This year-book keeps up its reputation and gives an excellent résumé of the leading literature in the different departments of medicine and surgery. It holds a high place among the various other compendiums in this line. The illustrations are excellent and add largely to the value of the books, which, so far as we have been able to examine, are trustworthy and full.

Miscellany.

In poisoning by morphin or by coal gas, remember the value of the abstraction of blood followed by saline infusion. In severe cases the addition of this measure to the others employed may be sufficient to save the life.

For Medical Writers.—Certainly it is excellent discipline for an author to feel that he must say all he has to say in the fewest possible words, or his reader is sure to skip them; and in the plainest words possible, or his reader will certainly misunderstand them. Generally, also, a downright fact may be told in a plain way; and we want downright facts at present more than anything else.—Ruskin.

Treatment of Gonorrhea Based on the Biologic Properties of the Gonococcus.—V. Schultz contributes to the "St. Petersb. Med. Woch." an article on this subject. He first establishes that the organism seeks to repel the invasion of the gonococci by filling up and obstructing with leucocytes the openings in the mucous membrane attacked and the lymphatics, thus localizing the infection. The cocci find in the leucocytes a nutrient medium peculiarly rich in peptone and in their proliferation in it they generate a toxin which in turn checks their own development. The infection is also blocked by early regeneration and metaplasia of the cellular tissue of the mucosa and the cocci are eliminated in the dead cells thrown off by the tissues. A fifth factor in the struggle of the organism is the febrile temperature, which probably has also an inhibiting influence. He cites authorities to the effect that the toxin generated by the cocci has an injurious influence on the nerves of the region, affecting in time portions of the entire central nervous system. Generally speaking, the columnar epithelium opposes the weakest and the pavement the strongest resistance to the invasion. On account of the penetrating power of the cocci, it is impossible to eradicate them mechanically or chemically unless the entire mucosa down into the submucous layers could be scraped off with them. The sole and entire reliance is, therefore, on the natural processes of defense. They must be promoted in every possible way. As aids in this line, he insists on entire avoidance of all excitement or stimulation of the region, sexual and menstrual. He packs the vagina of his female patients, and forbids them to remove the tampon. He also aims to induce a temporary menopause by intrauterine injections of iodin-alcohol, as recommended by Mackenrodt, Walton and others, or Sänger's method of applying the iodin-alcohol (Volkmann's Sammlung klin. Vorträge, 1890, 1894, 45 and 18, and Cbl. f. Gyn., 1894, 25). To rest the parts as much as possible, he orders his patients to stay in bed during the acute stage or an acute relapse. This is particularly essential during the menstruating period. Food, intestinal functions, etc., must be appropriately regulated, but the local process must be left entirely undisturbed, no instruments, disinfectants or local applications of any kind allowed. The seventh factor in his treatment is simultaneous treatment of the woman's husband if gonococci are discovered in his secretions. A great advantage would be gained if we could devise some way of inducing a local leucocytosis and febrile temperature to enhance the natural processes. Dehio has accomplished this in lupus patients by subcutaneous injection of extracts of the proteins of the prodigiosus and cyaneus bacilli.

A Sensible Veto.—The osteopaths had a vigorous lobby in Salt Lake City this winter, working for a law providing for licensing them to practice in the state on filing a certificate, without undergoing an examination, as is necessary for physicians. They succeeded in getting the bill passed, but it was vetoed by the governor, and failed to pass over the veto The following is Governor Wells' veto message, which we believe is worthy of space in our columns:

VETO OF OSTEOPATH BILL BY GOVERNOR HEBER M. WELLS, OF UTAH, MARCH 16, 1903.

To the Senate:

I herewith return without my approval Senate Bill No. 131, entitled "An Act declaring the practice of osteopathy not to be the practice of medicine and surgery within the meaning of title 52, revised statutes of Utah, 1898, and regulating the practice of osteopathy in the State of Utah."

The saving of human life, whether by means of looking to the prevention of disease or by means calculated to cure disease already established, will be admitted without question to be the proper climax of professional ambition as well as the highest humanitarian desire of legislative enactment. In both these directions the state of Utah, by vigorous sanitary laws and by strict requirements as to the quality of medical practitioners, stands well in the forefront of enlightened and progressive commonwealths.

Only through conviction should we venture to weaken in any degree these safeguards which experience and observation have proven to be beneficent and satisfactory.

PRACTICE OF MEDICINE.

Whatever the term or nature of the tenets of the particular school which this bill aims to recognize, its practice must, it seems to me, be considered a branch of the science of medicine. After all, the physician, of whatever school or designation, has to deal with the same physiology, the same conditions, the same laws of cause and effect in health and disease. All practitioners may not have the same knowledge and the same skill, yet our statutes have wisely provided as a matter of public policy and protection, that a certain amount of skilled knowledge all of them must have.

It requires considerable honesty in any practitioner to admit that a case in hand is beyond his powers. His training may be limited, his pretentions modest; but the consequences of his weakness in refusing to concede it are equally dangerous. The natural treatment of any physical disorder is necessarily determined by a diagnosis of a case—a preliminary of first and absolute importance. To do the wrong thing by performing dangerous manipulations, or to do nothing at all—either of which courses is easily open to the unskilled—may be equally fatal. The peril is not lessened if the physician, perhaps by happy accident or coincidence, has discovered the true condition.

HUMAN LIFE PRECIOUS.

He may be manly enough to confess inability to suggest proper remedies, or reckless enough to attempt treatment of his own altogether without reason or applicability, or indifferent enough, as already suggested, to do nothing at all. In either case the patient suffers the risk. Is not human life too precious to be thus trifled with?

The foregoing suggests that the treatment of disease should not be permitted to be a matter of mere experiment; and inasmuch as the authority to practice presupposed an acquaintance with the science as recognized by all the regular schools, any knowledge short of that should be deemed insufficient. I consider it unfair and dangerous, therefore, to allow the adherents of osteopathy or of any other school to practice without undergoing the ordinary tests to which other practitioners have to submit. The specialist may go so far as his talents and inclination may carry him, and the public be benefited by his advancement, but the fundamental and essential knowledge which every physician ought to have can not safely be waived or ignored.

SAFEGUARDS SWEPT AWAY.

Science is progressive; advancement can not be stayed, in the art of healing least of all; and the dogmatism of disputants, whether in medicine or anything else, must soon yield to the light of truth and reason. Whatever merit osteopathy may have will assuredly find recognition. The present contention is that in the bill before me the necessary requirements and safeguards with which the law surrounds the physically afflicted are thrown down and swept away. To this I am unwilling to consent. No practitioner of this school who possesses the qualifications required of the practitioners of other schools needs such a law. I deem it unwise to enact it for the benefit of those who have not those qualifications. Whenever all who seek to engage in the healing art shall be equally recognized as competent under the regulations now generally established, one medical law will be sufficient. This condition complied with it would give me sincere pleasure to name as a member of our state board of medical examiners an adherent of the very school in whose behalf this piece of legislation is proposed.

Heber M. Wells, Governor.

State Boards of Registration.

The New Oklahoma Law.—The recent Oklahoma legislature passed a new law regulating medical practice in that territory. It provides for a territorial board of health, consisting of three reputable physicians appointed by the governor, one of whom is to be a salaried official with the designation of superintendent and to be ex-officio the secretary. The law provides that the board shall meet every three months, due notice of time and place having been given. Aside from its other duties as a board of health, the board is to examine applications and grant licenses to practice medicine, and the act specifies the following conditions:

Section 5. No person hereafter shall practice medicine or surgery in this territory without first obtaining a license from the territorial board of health. Application for license shall be made in writing, together with a fee of $5, accompanied by a proof of good moral character, and proof of ten years' continuous practice, or proof of graduation from a reputable medical college. When the application has been inspected by the board and found to comply with the foregoing provisions, the board shall notify the applicant to appear for examination at a time and place designated in such notice. Examination shall be made in whole or in part in writing and be sufficiently strict to test the applicant's qualifications to practice medicine. All members of the board shall be present and participate in such examination. It shall be the duty *of the person holding such license to register in the office of the* register of deeds, in a book kept for that purpose, in the county in which person resides or intends to practice. Provided, that an osteopath shall not be required to pass an examination in materia medica or therapeutics.

Sec. 6. Any person practicing or offering to practice medicine or surgery in any of their branches, without first having obtained a license from this board, shall be deemed guilty of a misdemeanor and, on conviction thereof, shall be fined in any sum not less than $50 nor more than $100, or by imprisonment in the county jail for a period of not less than thirty days nor more than six months, or by both such fine and imprisonment at the discretion of the court, and all costs incurred therein.

Sec. 7. The provisions of this act shall not affect the rights of persons now legally practicing medicine, osteopathy or surgery in this territory; nor shall it prohibit the application of domestic remedies by one member of a family to another thereof; nor administering of remedies by another in case of emergency, without compensation; nor shall it apply to any commissioned medical officer of the United States army, navy or marine-hospital service, in the discharge of his official duties; nor to any legal qualified dentist, when engaged exclusively in the practice of dentistry; nor to any physician or surgeon from another state or territory who is a legal practitioner of medicine or surgery in the state or territory in which he resides, when in actual consultation with a legal *practitioner of this territory; nor to any physician or surgeon* residing on the border of a neighboring state or territory and duly authorized under the law thereof to practice medicine or surgery therein, whose practice extends into the limits of this territory: Provided, that such practitioner shall not open an office or appoint a place to meet patients or receive calls within the limits of this territory; nor to any osteopath who shall pass examination in the subject of anatomy, physiology, obstetrics and physical diagnosis in the same manner as required of other applicants before the territorial board of health, and who has thereupon received a certificate from the board which, when filed with the register of deeds, as is required in the case of other certificates from the board, shall authorize the holder thereof to practice osteopathy in the territory of Oklahoma, but shall not permit him to administer drugs nor to perform major surgery.

Association News.

THE SESSION AT NEW ORLEANS.

More Announcements Concerning the Fifty-Fourth Annual Session.

Full particulars of the rates and routes to New Orleans were given in the New Orleans Number, April 11.

Another special train is announced. The Chesapeake & Ohio Railroad special will leave New York at 4:55 p. m., Saturday, May 2, pass through Philadelphia and Washington and arrive at Hot Springs, Va., the next morning. The day will be spent there, the physicians being the guests of Mr. Fred Sterry, manager of the Homestead Hotel. Leaving Hot Springs Sunday night, the party will proceed to Louisville, where it will join other excursions on the Illinois Central. Those desiring to join this party should communicate with the agents of the road.

The Cuba Excursion.

A correspondent asks for further information concerning the trip from New Orleans to Cuba. He says: "Will you kindly state: 1, The time of arriving at Cuba; 2, if one may stay over one week and take steamer back on its second trip; 3, if $50 includes board and berth while on boat."

To this we answer: 1 Boats leaving New Orleans every Saturday arrive at Havana Monday, and leaving Havana Tuesday arrive at New Orleans Thursday. All schedules are subject to change, of course. 2. Yes, or two weeks, provided that will allow you to return home within the limit of your railroad ticket, May 30. Remember to extend your railroad ticket at New Orleans on or before May 12. 3. Yes.

Stomatology Meeting Place.

The meetings of the Section on Stomatology will be held in Touro Synagogue, Carondelet street, near St. Joseph street, instead of the location first announced.

Value Not Measured by Dollars and Cents.

The editor of "Merck's Archives" says that "any physician to whom it is at all possible should make the most strenuous effort to attend the meeting of the American Medical Association; the benefits derived from attending the meetings can not be figured out in dollars and cents; but the broadening of the intellect that comes from association with the best men of the profession from all parts of the country, the knowledge that one gains from listening to the papers and to the discussions, the acquaintances one makes, the social features and entertainments, the freedom from care and worry for a few days, and the *change from the humdrum life of the average practitioner—all* these factors are infinitely superior to dollars and cents, because they make the man a better physician and the physician a better man. So do your best to be at New Orleans on the date named. It is only one fare for the round trip."

Reception of Special Trains at New Orleans.

Those having charge of special trains to the New Orleans meeting of the American Medical Association are asked to notify the Chairman of the Bureau of Information, Dr A. G. Friedrich, 841 St. Charles street, New Orleans, as to where the special train will be from and at what time it will reach New Orleans. Such information should be sent by letter immediately, and also a telegram should be sent a few hours before the special reaches New Orleans, giving the expected time of arrival as near as possible.

House of Delegates.

The House of Delegates will be made up of the following delegates so far as we are advised. Those states not named have not appointed their delegates or have not sent in the names. Several states will be entitled to a larger representation than last year.

Arkansas—Dr. J. A. Dibrell, Little Rock.

California—Dr. H. Bert Ellis, Los Angeles.

Colorado—Dr. C. K. Fleming, Denver.

Connecticut—Dr. C. S. Rodman, Waterbury; Dr. C. E. Brayton, Stonington.

District of Columbia—Dr. George M. Kober.

Florida—Dr. R. D. Murray, Key West.

Indian Territory—Dr. B. F. Fortner, Vinita.

Indiana—Dr. W. N. Wishard, Indianapolis; Dr. D. C. Peyton, Jeffersonville.

Iowa—Dr. J. R. Guthrie. Dubuque; Dr. Samuel Bailey, Mt. Ayr.

Kansas—Dr. J. E. Minney, Topeka.

Kentucky—Dr. J. N. McCormack, Bowling Green; Dr. Thomas Hunt Stucky, Louisville.

Louisiana—Dr. Rudolph Matas, New Orleans.

Massachusetts—Dr. W. N. Swift, New Bedford; Dr. A. G. Minshall, Northampton; Dr. B. H. Hartwell, Ayer. Dr. W. T. Councilman, Boston; Dr. J. C. Warren, *Boston; Dr. H. E. Marion, Brighton.*

Michigan—Dr. H. O. Walker, Detroit; Dr. T. A. Felch, Ann Arbor; Dr. J. B. Griswold, Grand Rapids.

Minnesota—Dr. A. W. Abbott, Minneapolis; Dr. Wm. Davis, St. Paul.

Missouri—Dr. F. J. Lutz, St. Louis.

Montana—Dr. T. J. Murray, Butte.

New Hampshire—Dr. Ira J. Prouty, Keene.

New Jersey—Dr. Chas. J. Kipp, Newark; Dr. Elias J. Marsh, Paterson; Dr. L. M. Halsey, Williamstown.

North Carolina—Dr. E. C. Laird, Hot Springs; Dr. E. B. Glenn, Asheville.

Oklahoma—

Oregon—Dr. Andrew C. Smith, Portland.

Pennsylvania—Dr. William T. Bishop, Harrisburg; Dr. H. S. McConnel, New Brighton; Dr. John B. Roberts, Philadelphia; Dr. Wm. M. Welch, Philadelphia; Dr. Wm. S. Foster, Pittsburg; Dr. Geo. W. Guthrie, *Wilkesbarre; Dr. Alem P. Hull*, Montgomery; Dr. W. B. Lowman, Johnstown.

Rhode Island—Dr. John Champlin, Westerly; Dr. Frederick T. Rogers, Providence.

South Dakota—Dr. J. L. Stewart, Irene.

Tennessee—Dr. Dan'l E. Nelson, Chattanooga; Dr. Louis LeRoy, Nashville.

Texas—Dr. H. A. West, Galveston.

Washington—Dr. Park W. Willis, Seattle.

West Virginia—Dr. L. D. Wilson, Wheeling.

Wisconsin—Dr. W. T. Sarles, Sparta; Dr. Herman Reineking, Sheboygan.

Wyoming—Dr. E. E. Levers, Spring Valley.

Medical Organization.

A Plea for Uniformity.

The importance of practical uniformity in the essential features of organization in every state in the Union is so great, and has so constantly grown on all of those who have had opportunity for observing the work in the states which adopted plans of reorganization last, that an earnest plea is made to those who have the matter in charge in other states not to depart from the Association plan lightly or in the absence of the most obvious reasons for doing so. In fact, one of the prime objects of the movement from the outset was to get rid of the crazy-quilt system, or, rather, the lack of system, which stood in the pathway of every effort at legislative and other reforms in the past and secure such unity of both purpose and methods as would make the voice of the profession effective in securing every desirable advancement. The plan has now been so fairly and successfully tested, under such varied conditions and in widely separated states, as to demonstrate its adaptability to use in any state, and is no longer a matter of experiment.

The four essential features provided in the constitution and by-laws for state societies are so interdependent, so to speak, that no one of them can be cut out without irreparable injury and injustice to the plan as a whole for practical purposes. This is not a matter of experiment either, but the statement is based on the experience and actual results in those states which reorganized last year, but which left out one or more features, usually the House of Delegates, as compared with what has been accomplished in the same time and under very similar conditions in the still larger number of states which accepted it as a whole.

The four essential features of the Association plan, named in the order of their importance, are: 1. The county society as the unit of organization, and the foundation for everything above it. 2. The House of Delegates, composed of a specially selected and limited number of representatives from the county societies, to look after and foster the business, legislative and all material interests of the profession. 3. A Council, to be selected from the profession at large, each to cover a definite territory, and to represent every section of the state, to act for it under well-defined restrictions in the interval between meetings. 4. The General Meeting, composed of all the members of all the county societies who will attend, which can devote its entire time and attention to the reading and discussion of papers and other scientific work as well as social, it being relieved of the miscellaneous business duties which consumed so much time in the past with so little profit, and of the election of officers, which was another fruitful source of distraction and discontent.

If time and space permitted, these features might be profitably elaborated, but this is done so fully in the official constitution and by-laws as to make it less important Others, again, might change the order in which these features or sections of the plan are stated, but when it is understood that the ultimate purpose is to make the county society not only a means of promoting good fellowship and of promoting the material interests of all under its jurisdiction, but of making it, if even in a humble way at first, a post-graduate school, which the General Meeting is in a broader sense for the fortunate ones who can attend it, brought at short intervals within the reach of all.

Now, it is true that much contained in the by-laws, where a wide departure is made from the brevity and compactness of expression observed in the constitution, is explanatory, suggestive and educational in character, and much is embraced which would not be necessary if such an organization as is contemplated was already in existence. In justification for this it is submitted that, under existing conditions, it is almost as important to furnish incentives to this work, to give practical and detailed information as to how it is to be done, and to put the reasons for all of it within easy reach of those who, as councilors and volunteers, will discuss the subject from one end of the country to the other, as to furnish the foundation and framework of the superstructure set forth in the constitution.

After the organization has been accomplished, which will require more time and self-sacrificing labor than is generally understood, anything found obsolete or impracticable can be easily eliminated or replaced by provisions better adapted to needs then existing.

Committees on organization yet to report, and members of state societies which have not reorganized, are urged to give this subject the grave consideration to which it is entitled, and especially are they urged not to change a plan designed and recommended by the American Medical Association for universal adoption, after much labor and expense, merely for the sake of change. Doubtless another committee might have devised something better, but, conceding this to be true, a departure from it now can not be otherwise than a step backward. If the profession of any state is not sufficiently advised or for any other reason is not ready to act favorably on the plan as a whole, it will be far better, in the light of the experience of those states which acted differently, to postpone action for another year. However well intended, any other course is unjust to and is likely to bring discredit on the entire plan of organization, and in the end will work an injustice on the profession of the state where it is done.

J. N. McCormack.

Iowa.

Grundy County.—The physicians of Grundy County met at Grundy Center, April 7, and organized a medical society, with Dr. Eugene A. Crouse, Grundy Center, president; Dr. William N. Moffett, Conrad, vice-president; Dr E. H. Hoefer, Reinbeck, secretary, and Dr. M. H. Theilen, Grundy Center, treasurer.

Kentucky County Societies.

Bourbon County.—Dr. Louis Frank, Louisville, reports the organization of this society with Dr. Wilson G. Daily, Millersburg, president; Dr. Charles G Daugherty, Paris, secretary-treasurer, and Dr. Silas Evans, Paris, delegate.

Hart County.—The physicians of Hart County met, April 15, and organized this society, with Dr. C. J. Walton, Munfordville, president; Dr. Thomas H. Garvin, Horse Cave, vice-president; Dr. Jesse J. Adams, Munfordville, secretary-treasurer; and Dr. B. L. Bruner, Hardyville, delegate.

Crittenden County.—Dr. James H. Letcher, Henderson, reports the perfection of the organization of this society, with Dr. Isaac H. Clement, Tolu, president; Dr. J. William Trisler, Marion, vice-president; Dr. William T. Daughtrey, Marion, secretary, and Dr. J. O. Dixon, Marion, delegate.

Grant County.—The physicians of Grant County met at Williamstown, April 13, and organized a county society, adopting the constitution and by-laws of the American Medical Association, after an address by Dr. Joseph E. Wells, councilor for the adjoining Ninth District. Dr. John M. Wilson, Williamstown, was elected president, and Dr. William Robinson, Corinth, secretary.

Graves County—The physicians of Graves County met at Mayfield, April 14, and, after an address by the president of the state association, organized a county society, electing Dr. John L. Dismukes, Jr., Mayfield, president, and Dr. Milford W. Rozzell, Mayfield, secretary. The constitution and by-laws proposed by the American Medical Association were adopted without change.

Franklin County.—The physicians of Franklin County met at Frankfort, April 15, and organized a county society, after a talk by Dr. Louis Frank, councilor of Louisville district. The constitution and by-laws of the Association were adopted. A list of the officers has not been received.

Livingston County.—The physicians of Livingston County met at Smithland, April 13, and organized a county society, after an address by Dr. James T. Reddick, Paducah. The constitution and by-laws suggested by the American Medical Association were adopted without change. The following officers were elected: President, Dr. Frederick G. LaRue, Smithland; vice-president, Dr. Oliver R. Kidd, Carrsville; secretary, Dr. Edward Davenport, Hampton; treasurer, J. E. Chipps, Birdsville; and delegate to the state association, Dr. John V. Hayden, Salem.

Mississippi.

At its annual meeting held at Vicksburg, April 15-17, the Mississippi State Medical Society adopted the Association plan of organization without a single change. The constitution and by-laws were reported favorably by the committee on organization in 1902, and had lain on the table for a year. It was taken up at the opening of the meeting this year and referred to a large committee, representing every section of the state, which went over the whole matter thoroughly and again made a favorable report. As some of the members did not understand all that proposed, it was read section by section in the society, and then adopted without a dissenting vote.

The state was divided into ten councilor districts, with special reference to lines and convenience to travel for the councilor in each, and the following were appointed as members of the council: E. H. Martin, Clarksdale; K. P. Perkins, Batesville; C. D. Mitchell, Pontotoc; W. M. Paine, Aberdeen; J. A. Crisler, Yazoo City; W. D. Kiger, Brunswick; O. B. Quin, McComb City; J. R. Packett, Meridian; D. J. Williams, Ellisville and H. M. Folkes, Biloxi.

A resolution was adopted, authorizing the secretary, on recommendation of the councilors, to recognize and issue charters to county societies. He was also instructed to procure and distribute to the profession of Mississippi 3,000 copies of the new constitution and by-laws, sending with each of these a copy of the constitution and by-laws for county societies An appeal was made to every reputable physician in the state to join his county society, and through it his state association.

The following officers were elected: President, Dr. Chas. D. Mitchell, Pontotoc; vice-presidents, Drs. Joseph Waldauer, Vicksburg; May F. Jones, Columbus, and C. L. Culley, Jackson; secretary, Dr. J. J. Haralson, Forest; treasurer, Dr. J. F. Hunter, Jackson.

The officers and council were carefully selected with reference to the large amount of work to be done during the next year, and the promise is for excellent results. The medical and health laws of Mississippi are nearly all that can be desired, but their enforcement has been crippled in the past by a lack of unity in the profession. With a good organization almost anything desirable is within its reach J. N. McCormack.

Missouri.

As we go to press information comes that the Missouri State Medical Association, which has been in session this week, has adopted the constitution and by-laws for state societies endorsed by the American Medical Association, with practically no modifications. Thirty-six component societies, with a membership of 1,088, were reported.

Nebraska County Societies.

Brown County.—On April 8 physicians of Brown County met at Long Pine and organized a county medical society, with Dr Harmon P. McKnight, Long Pine, president; Dr. H. A. Brown, vice-president, and Dr. G. O. Remy, Ainsworth, secretary-treasurer.

Nance County.—The physicians of Nance County met at Fullerton, April 8, and organized a medical society to be affiliated with the state and national associations. Dr. Edward Johnson, Fullerton, was elected president; Dr. Charles W. Ford, Belgrade, vice-president, and Dr. Dora M. Judkins, Fullerton, secretary-treasurer.

Tennessee County Societies.

Wilson County.—Wilson County physicians met recently at Lebanon and organized a county society, with Dr. John W. McFarland, Lebanon, president.

Carter County.—The medical profession of Carter County met at Elizabethton, and organized a county society with Dr. J. H. Alexander, Elizabethton, president

Houston County.—This society was organized at Erin, April 6, with Dr. Alfred H. Abernathy, Erin, president; Dr. G. D. Boone, Erin, vice-president; Dr. W. H. McMillan, secretary, and Dr. R. H. Baylor, Erin, treasurer.

Societies.

COMING MEETINGS.

AMERICAN MEDICAL ASSOCIATION, FIFTY-FOURTH ANNUAL SESSION, NEW ORLEANS, MAY 5-8.

Texas State Medical Association, San Antonio, April 28.
Louisiana State Medical Society, New Orleans, April 28-30.
Medical and Chirurgical Faculty of Maryland, Baltimore, April 28-30.
Nebraska State Medical Society, Lincoln, April 28-30.
Illinois State Medical Society, Chicago, April 29-May 2.
Arkansas Medical Society, Jonesboro, April 30-May 2.
Association of American Medical Colleges, New Orleans, May 4.
American Proctologic Society, New Orleans, May 5.
Kansas Medical Society, Concordia, May 6-9.
American Urological Association, New Orleans, La., May 8-9.
American Academy of Medicine, Washington, D. C., May 11-12.
American Therapeutic Society, Washington, D. C., May 11-13.
Oklahoma Territorial Medical Association, Guthrie, May 12.
American Association of Genito-Urinary Surgeons, Washington, D. C., May 12-14.
American Surgical Association, Washington, D. C., May 12-14.
American Orthopedic Association, Washington, D. C., May 12-14.
American Pediatric Society, Washington, D. C., May 12-14.
Association of American Physicians, Washington, D. C., May 12-14.
American Medico-Psychological Association, Washington, D. C., May 12-15.
American Ophthalmological Association, Washington, D. C., May 13-14.
Association of Military Surgeons of the United States, Boston, May 19-21.
New Hampshire Medical Society, Concord, May 21-22.
North Dakota State Medical Society, Bismarck, May 21-22.
South Dakota State Medical Society, Mitchell, May 27-28.
Connecticut Medical Society, Hartford, May 27-28.

Congress of American Physicians and Surgeons.—The sixth triennial session will be held in Washington, D. C., May 12, 13 and 14.

Knox County (Tenn.) Medical Society.—At the annual meeting, at Knoxville, April 2, Dr. Ernest R. Zemp, Knoxville, was elected president.

Cass County (N. D.) Medical Society.—At the annual meeting, held in Fargo, March 30, Dr. Hezekiah J. Rowe, Casselton, was elected president

National Association of United States Pension Examining Surgeons.—The second annual meeting will be held in Washington, D. C., May 13 and 14.

Washington County (Iowa) Medical Society.—At the annual meeting, held in Washington, April 8, Dr. George W. Hay was re-elected president and Dr. Cloyd A. Boice secretary, both of Washington.

Marshall County (Ind.) Medical Society.—At the meeting, held in Plymouth, April 9, Dr. R. Clarence Stephens was elected president; Dr. Adolphus C. Holtzendorff, vice-president, and Dr. Novitas B. Aspinall, secretary, all of Plymouth.

Baltimore Pediatric Society.—A society was organized last week for the promotion of the department of pediatrics. Dr. Charles W Mitchell was elected president, and Dr. Henry M. Fitzhugh secretary. Meetings will be held monthly.

Pulaski County (Ill.) Medical Society.—At the annual meeting Dr. John F. Hargan, Mound City, was elected president; Dr. William C. Rife, Villa Ridge, vice-president, and Dr. A. Willard Tarr, New Grand Chain, secretary and treasurer.

Lyon County (Kan.) Medical Society.—The twentieth annual meeting was held in Emporia, April 7, at which Dr. John M. Parrington was elected president; Dr. Frank Eckdall, vice-president, and Dr. John M Poindexter, secretary and treasurer, all of Emporia.

Howard County (Md.) Medical Society.—At the annual meeting of this body, at Ellicott City, April 7, Dr. John W. Lacy, Lisbon, was elected president; Dr Bernard J. Byrne, Ellicott City, vice-president, and Dr. William B. Gambrill, Alberton, secretary and treasurer.

Lauderdale County (Tenn.) Medical Society.—At the annual meeting, held in Ripley, Dr. Alexander H Young, Ripley, was elected president; Dr. William H. Tucker, Double Bridges, vice-president; Dr. Gustavus A. Lusk, Ripley, secretary, and Dr. W. D. Miller, treasurer.

Jefferson County (Ark.) Medical Society.—This society, at its annual meeting at Pine Bluff, April 8, elected Dr. William H. Blankenship, Altheemer, president; Dr. J. William Scales, Pine Bluff, vice-president, and Dr. William Crutcher, Pine Bluff, secretary and treasurer.

Cass County (Ill.) Medical Society.—The annual meeting was held at Virginia, April 8, Dr. George Bley, Beardstown, was elected president; Dr Daniel Lyons, Ashland, vice-president; Dr. John A. McGee, Virginia, secretary, and Dr. John G. Franken, Chandlerville, treasurer.

Richland County (Ohio) Medical Society.—The annual meeting was held at Mansfield, April 4. Dr. M. T. Love, Shelby, was elected president; Dr S. Edwin Findley, Mansfield, vice-president; Dr. J. Lillian McBride, Mansfield, secretary, and Dr. Emma Millikin, Ontario, treasurer.

Orange County (Cal.) Medical Society.—At the meeting, held in Fullerton, April 7, Dr. William Freeman, Fullerton, was elected president; Dr. Foster E. Wilson, Westminster, vice-president; Dr. Howard S. Gordon, Westminster, secretary, and Dr. James R. Medlock, Santa Ana, treasurer.

Western Alumni Association of the University and Bellevue Hospital Medical College.—The third annual banquet will be held at the Sherman House, Chicago, April 30, at 6:30 p. m. Dr. George N. Kreider, Springfield, is president of the association, and Dr. Willis O. Nance, Chicago, secretary.

Golden Belt Medical Society.—At the annual meeting, in Abilene, Kan., Dr. John D. Riddell, Enterprise, was elected president; Dr. Edward W. Hawthorne, Gypsum, vice-president; Dr. Albert A. Shelley, Abilene, secretary, and Dr. Lamorte R. King, Junction City, treasurer. The next meeting will be held at Salina in July.

Jersey County (Ill.) Medical Society.—The forty-seventh annual meeting was held in Jerseyville, April 8, Dr. Augustus K. Van Horne, Jerseyville, retiring president, was the only survivor of the founders of the society. Dr Allen A. Barnett was elected president; Dr. John S. Williams, vice-president, and Dr. Henry R. Gledhill, secretary and treasurer, all of Jerseyville.

San Diego County (Cal.) Medical Society.—At the annual meeting, held in San Diego, April 3, the following officers were elected: President, Dr. Fred Baker, San Diego; vice-president, Dr. William V. Nichols, Oceanside; secretary and treasurer, Dr. Thomas L. Magee, San Diego, and delegate to the Medical Society of the State of California, Dr. Fred R. Burnham, San Diego.

Marion County (Ohio) Medical Society.—The first meeting of the merged Marion County Medical Society and Marion Academy of Medicine was held at Marion, April 7. Dr. Robert Ramroth was re-elected president; Dr. Charles E. Sawyer, elected vice-president, and Drs. Herman S. Rhu and Francis B. Sawyer were re-elected secretary and treasurer respectively, all of Marion.

buqu (Iowa) Medical Society.—The fifteenth anniversary
y will be celebrated by a special meeting, June
h papers are to be read by Drs. C. H. Mayo,
n, and **G. F. Lydston,** Chicago. In the afternoon
n he
participated in by Drs. Hugh
A. Wood and Norval H.
Lewis, Dubuque.

Society.—At the annual meet-
pril 2, and reported in The Journal
ffiliating the society with the Illinois
the American Medical Association
majority. Drs. Charles M. Noble,
H. Fenelon, all of Bloomington,
William R. Shinn, Chenoa, and
n, delegates to the state

the Prevention of Tuberculosis.—At
in Philadelphia, April 8, Dr. Howard
ess, urging the necessity for a popular
for the spread of practical knowledge
. A. Knopf, New York, also addressed
suggested, a committee being appointed
, was that of public lectures. A com-
o assist in the enforcement of the anti-
ntly passed by councils. Dr. Howard
d president.

almology and Oto-Laryngology.—The
and Oto-Laryngologic Association held
polis, April 9, 10 and 11. It was
ame of the organization to the Academy
Oto-Laryngology. The following officers
ward Jackson, Denver, president; Drs.
ouisville, John J. Kyle, Indianapolis, and
cinnati, vice-presidents; Dr Derrick T. Vail, Cincinnati, secretary, and Dr. Otto J. Stein, Chicago, treasurer. A resolution was adopted urging the state boards of health throughout the United States to secure the attention of street car and steam railway companies for an early consideration of the sanitary and therapeutic value of noiseless car wheels.

Iowa State Medical Society.—The fifty-second annual meeting was held at Sioux City, April 15 to 17. The new constitution and by-laws in conformity with the plan of reorganization were read by Dr. Van Buren Knott, Sioux City, in the absence of Dr. David S. Fairchild, Clinton, and after a little discussion, were adopted unanimously. The following officers were elected: President, Dr. Joseph A. Scroggs, Keokuk; vice-presidents, Drs. Donald Macrae, Jr., Council Bluffs, and Dallis M. Wicks, Cedar Falls; secretary, Dr. Vernon L. Treynor, Council Bluffs; assistant secretary, Dr. Francis A. Ely, Des Moines; treasurer, Dr William B. Small, Waterloo; trustees, Drs. Gilbert G. Cottam, Rock Rapids, and Daniel W. Finlayson, Des Moines; and member of the House of Delegates of the American Medical Association, Dr. Samuel Bailey, Mount Ayr, for two years. Des Moines was selected as the next place of meeting.

International Housing Congress.—This congress, which is to be held from July to November at the Grand Palace, in the Champs Elysees, is to have an American committee, of which Richard Watson Gilder of New York has just been made chairman. The other members of the committee are: M. E. Ingalls, Cincinnati; William B. Howland, Dr. E. R. L. Gould and James H. Hyde of New York; Carroll D. Wright of Washington; Albert Shaw of New York; Robert Garrett of Philadelphia. The object of the congress is to show the world the great need for improvement in both rural and city homes for workmen and clerks, and to this end there will be a collection from many countries of models of improved houses, of materials and methods of construction, and of furniture and decorations. There will also be models to show the sanitary, or, rather, unsanitary conditions in factories and many other places in which men work It is expected that the work of the congress will exert a potent influence in the control of consumption and alcoholism.

Tennessee State Medical Association.—The seventieth annual meeting, held in Nashville, April 14, 15 and 16, was the first meeting since the new constitution and by-laws came in force. The attendance was double that at any previous meeting. The prize for the best essay was awarded to Dr. Edward C. Ellett, Memphis. The following officers were elected: President, Dr. Isaac A. McSwain, Paris; vice-presidents, Drs. William H. Sale, Covington, Louis Leroy, Nashville, and Claude P. Fox, Greeneville; secretary, Dr. Deering J Roberts, Nashville (re-elected), and treasurer, Dr. William C. Bilbro, Murfreesboro. As the society at this meeting passed the thousand mark on its membership roll, it was entitled to three members of the House of Delegates of the American Medical Association. The following were elected: Dr. Louis Leroy, Nashville, to succeed Dr. W. Frank Glenn, resigned; Dr. James B. Murfree, Murfreesboro, to succeed Dr. George C. Savage, Nashville, resigned on account of ill-health; Dr. Daniel E. Nelson, Chattanooga, delegate for two years, and Dr. William B. Sanford, Memphis, alternate; Dr. Jeremiah L Crook, Jackson, delegate, with Dr. W. J. Miller, Johnson City, alternate. The next meeting will be held in Chattanooga.

AMERICAN MEDICAL ASSOCIATION.

Meeting of the Section on Hygiene and Sanitary Science, Saratoga Springs, N. Y., June 10, 1902.

The Chairman of the Section, Dr. Arthur R. Reynolds, Chicago, in the chair.

Symposium on Boards of Health and the Manufacture of Vaccine Lymph and Antitoxin.

The Chairman—Dr. Marcy suggests that we consider the manufacture of vaccine and antitoxin.

Dr. H. O. Marcy, Boston—The question is one which is exciting a great deal of attention in Massachusetts at present. The State Board of Health has for some time been making its own antitoxin, and now it is proposed to give it power to make vaccine lymph as well. The issue is: Shall we rely on large and reputable firms, like Parke, Davis & Co. and the New England Vaccine Company, as we have been doing hitherto, or will it be better to let the board of health organize another department and manufacture its own? Is it wise, in other words, to further extend the paternal influence of the state, or should we continue to rely on private manufacturers?

Dr. S. A. Knopf, New York City—I am not a health officer, but I have been present at meetings in New York where this subject has been discussed. I recall particularly a meeting under the auspices of the Society of Medical Jurisprudence, at which there were present representatives of the health departments of the city and state, and also representatives of commercial houses manufacturing vaccines. The discussion was very heated. Of course, the representatives of the manufacturers claimed that in a free country they had a right to manufacture vaccine lymph and antitoxin, and the health department of the city maintained that it had a right to do the same. During the discussion it was stated that some inferior antitoxin had been sold by the health department of New York City to the health department of Chicago. Possibly the chairman will be able to tell us something about that. I took part in the discussion at the close, and I may be allowed to repeat here the substance of what I said then. I took the position that we had no right to prevent the private manufacturers from continuing to make these preparations, but that, on the other hand, boards of health had also a right to make them. What, however, I considered of most importance was that every state should have a control laboratory, and that no vaccine or antitoxin should be allowed to be put on the market until it had been tested and passed by that institution. Only in this way, I believe, can we rely on getting the best possible products for our patients.

Dr. Benjamin Lee, Philadelphia—This is a question that has been forced on the attention of all of us in a very pointed manner during the last two or three years. The position which I have been inclined to take is, that the necessity the mercantile producer is under of keeping up his product to a proper standard if he wishes to sell it probably affords a greater safeguard than would be assured by placing the matter in the hands of men appointed by state governments, who, unfortunately, are too often appointed simply for political reasons. At the same time, we can not shut our eyes to the fact that there have been occurrences in this country during the past two years which go to show that some of the commercial virus has been absolutely inert, and some of it, on the other hand to a greater or less extent, dangerous. I believe the solution of the problem is to be found very much on the lines suggested by Dr. Knopf—that we should not prevent the production of commercial vaccine, but that each board of health should exercise a power of supervision and should see that no virus is foisted on the public which is either ineffective or likely to be dangerous. I was talking yesterday to a former member of the Pennsylvania Board of Health, who for nearly two years supervised the sanitary work in Porto Rico when the island was in charge of the United States Army, and he informed me that all the virus imported from this country—whether obtained from the New York Board of Health or from private manufacturers—was absolutely inert except in the case of one manufacturer, who produced what he called a triple-charged point. That was successful in some instances, but all the others were inert, and the way they met the problem was this: With some of this triple-charged virus they inoculated a number of calves, and driving these calves from town to town vaccinated the people direct from the animal. The result was that very soon and for some time thereafter there was not a case of smallpox to be found on the island, whereas when the army first went there the disease was rife. He tells me, however, that smallpox is now beginning to make its reappearance, and that it will be necessary to investigate the matter with the view of discovering the causes.

Dr. C. B. Johnson, Champaign, Ill.—Several years ago, in response to the solicitations of the Illinois State Medical Society, the University of Illinois established a vaccine laboratory on its grounds at Champaign. This has since been in operation and is under the care of able men, professors in the university. They make good, reliable vaccine, but other manufacturers come in the town and sell their products, and in other parts of the state the University of Illinois vaccine has by no means had the patronage it deserves. Just why this is true I am unable to say, unless it be that the commercial motive is necessarily lacking to properly place the Illinois product on the market.

Dr. Marcy—Do they sell it?

Dr. Johnson—At first they did not, but conceiving this to be unfair to other manufacturers the University of Illinois vaccine is now sold at the usual prices.

Dr. H. D Holton, Brattleboro, Vt.—Do they make points?

Dr. Johnson—Yes, they make points, and recently tubes also.

Dr. Seneca Egbert, Philadelphia—My views are very much the same as have been expressed by Dr. Lee. I feel that, as a rule, we are safer to trust to large firms, whose regular business it is to make these products, and whose interest it is to maintain the quality of their goods. At the same time, there is this to be taken into account. About six months ago the demand for vaccine lymph became so great that there was ground for believing certain firms shaved things a little and ran risks. One day I heard over the luncheon table of a certain firm having run out of vaccine lymph, and buying another firm's product, on which they put their own label. It may have been only gossip, but if true this clearly was not right. Even if one firm's was as good as another, it was a wrong thing to do, for the firm which bought the lymph knew nothing of their own knowledge as to its quality. While no one may be able to put his finger on the cause of tetanus following vaccination, it is at least possible that some firm was induced by the pressure of business to become careless. Such a thing might not occur again for a hundred years, but, as I have said, it is one of the things that have to be taken into account in considering this matter. A good, thorough examination of all these preparations would be an additional precaution against the possibility of such a thing, and, what is more, it would give the public a feeling of confidence that they do not have now. It is going to be hard in the near future to vaccinate the people in Philadelphia, even if we use all our powers of persuasion and do what we can to show them the advantages of it, for many have at present the fear of the graver danger of tetanus.

Dr. H. M. Bracken, Minneapolis—The question of control laboratories is an interesting one. The legislative committee discussed it at its February meeting in Washington, and the general opinion was in favor of central inspection. It was very much doubted if any system by which the work should be carried on by individual states would be satisfactory. It might be all right in some states, but not in others, and it is obvious that any such system of inspection should be uniform. For that reason it was agreed that it should be federal inspection if possible. I believe that as a rule the interest of the manufacturer in keeping up the quality of his goods will secure for us as good qualities of vaccine virus and antitoxin as we can get through the state laboratories. Their interests are involved to such an extent that they can not afford to run any risks, and they would probably be even more careful than the state laboratories. If all the states had Theobold Smiths at the head of their laboratories it might be perfectly safe to trust to them; but it is well known that not all have men of his standing, and that they can not get them. In fact, in some places it is hardly possible to get good men to take up this kind of work.

Sometimes the state may advantageously produce certain of these products, but I do not think they should ever do so with a view to commercial gain. State products should always be for free distribution. There is no reason whatever for any of our state boards of health to go into commercial enterprises.

Dr. Lee has referred to the fact that vaccine virus imported into Porto Rico from the United States was found to be inert. That, I would like to point out, may have been due to climatic influences. It is well known that vaccine virus loses its efficacy when exposed to a high temperature, and that glycerinated vaccine is easily rendered inert in this way. It is natural that they should get better results in Porto Rico when they inoculated direct from the calf. I hope

Picric acid is an old-time remedy which is said to serve as an analgesic, an antiseptic, and has keratogenetic powers. It may be combined as follows:

℞.	Acidi picrici	ʒss	2	
	Spts. vini	ʒx	40	
	Aq. destil q. s. ad	℥xiv	420	

M Sig.: Apply locally.

The lesion should be thoroughly cleansed with this solution, used on absorbent cotton. The blebs should then be opened, allowing the skin to remain. Strips of gauze soaked in the solution should be applied and allowed to remain for four or five days, when a new dressing should be applied.

In burns of the second and third degree more satisfactory results, according to the author, are obtained by dry dressings with antiseptic powders such as airol, xeroform, and nosophen, as these preparations are harmless and are to be applied in full strength. Salves may be substituted, made up as follows:

℞.	Airol	ʒi	4	
	Lanolini anhyd.			
	Liq petrolati, āā	ʒiv	15	

M. Ft. unguentum. Sig.: Apply locally and cover with gauze and absorbent cotton, and allow the dressing to remain intact for several days; or:

℞	Ichthyol	gr. xlv	3	
	Olei olivæ (sterile)	ʒiiss	10	
	Lanolini			
	Liq. petrolati, āā	ʒx	40	

M. Ft. unguentum. Sig.: Apply locally; or:

℞.	Sol. plumbi subacet.	ʒiss	6	
	Olei lini (sterilized)	ʒiiss	10	
	Xeroformi q. s. ad	℥i	30	

M. Ft. unguentum. Sig.: Apply freely on gauze.

Rachitis.

Comby, in "Med. Press," states that he has obtained the best results from the following in the treatment of rickets:

℞.	Olei morrhuæ	℥iv	120	
	Sol. calcii lacto-phos. (50 per cent.)	℥i	30	
	Syr. lacto-phos.	℥iii	90	
	Tinct. cinnamomi	m. lxxv	5	

M. Sig.: Two to five teaspoonfuls daily; or:

℞.	Essentiæ limonis	gtt. ii		12
	Phosphori	gr. 1/6		01
	Sacchari	℥i	30	
	Olei amygd. dulcis	℥iiss	75	

M. Sig.: One teaspoonful daily

Treatment of Wounds.

Sleich, according to the "N. Y. Med. Jour.," recommends the following topical applications that are nutrient to the tissues and non-irritating:

PEPTONIZED PASTE.

℞.	Peptone (dry)			
	Amyli			
	Pulv. zinci oxidi, āā	℥ss	15	
	Pulv. acaciæ	℥i	30	
	Lysol	gtt. v		30
	Aq. destil. q. s.			

M. Ft unguentum. Sig.: Apply locally.

SERUM PASTE.

℞.	Seri bovis	℥ii	60	
	Zinci oxidi	℥i	30	

M. et fiat pulvis.

After the foregoing is dried and reduced to a powder the following mixture is then prepared:

℞.	Pulv. seri et zinci oxidi	℥i	30	
	Aquæ	℥ss	15	
	Peptonic paste	ʒii	8	

M. Sig.: Apply locally.

The author especially recommends the foregoing as an application to varicose ulcers.

In the treatment of syphilis the following is recommended by the author as a local application:

℞.	Ung hydrarg.	℥i	30	
	Peptonic paste	℥ii	60	
	Olei theobrom.	ʒiii	12	
	Aq. destil.	ʒiii	12	

M. Sig.: Apply locally.

Baldness.

The following combinations are recommended by "Merck's Report" in the treatment of baldness:

℞.	Plumbi acetatis	ʒiss	6	
	Sulphuris precip.	ʒii	8	
	Tinct. cantharidis	ʒi	4	
	Glycerini	℥ii	60	
	Alcoholis	℥i	30	
	Olei citronellæ	m. xv	1	
	Olei bergamot	m. viii		50
	Aquæ q. s. ad	Oi	480	

M. Sig.: Apply locally to the scalp; or:

℞.	Sulphuris precip.	ʒii	8	
	Plumbi nit.	ʒiss	6	
	Tinct. cantharidis	ʒii	8	
	Glycerini	℥ii	60	
	Alcoholis	℥i	30	
	Olei lavendulæ	m. xxx	2	
	Olei amygd. (essential)	m. iv		25
	Aquæ q. s. ad	Oi	480	

M. Sig.: Apply locally.

Phosphorus in Alopecia.

According to an abstract in "Month. Cyc. of Med.," phosphorus in small doses is of great service in the treatment of alopecia areata. The following formula is recommended:

℞.	Phosphori	gr. i		06
	Olei olivæ, q. s. ad. solutio			

Then add:

	Acidi arsenosi	gr. ii		12
	Excip. q. s.			

M. Ft. pil. No. cxx. Sig.: One pill to be taken daily for two months, followed by an intermission of one week until three hundred pills are taken, when a cure is generally effected.

Substitutes for Potassium Iodid.

On account of the after-effects produced by the administration of potassium iodid, Solis-Cohen reviews, in "Amer. Med.," other preparations which may be substituted for this preparation. Among these substitutes he mentions iodized starch containing 5 parts of iodin and 95 parts of starch given usually in doses ranging from grains 3 to 10 (.2-.6). However, it has been given in gradually-increased doses reaching ½ ounce (15.). Locally this preparation is of service in the treatment of sluggish ulcers from any cause.

Iodoform may also be given as a substitute for potassium iodid in doses ranging from 30 to 80 grains (2.-5.).

Locally it may be applied as follows:

℞.	Iodoformi	ʒiv	15	
	Balsami peruvianæ	ʒii	8	
	Lanolini	℥ii	60	

M. Sig.: To be applied locally.

Iodol is not infrequently given in doses ranging from 6 to 30 grains a day (.4-2.). In the treatment of angina pectoris the author quotes the following formula employed by Maldorescu:

℞.	Iodol	gr. xxx	2	
	Ext. glycyrrhizæ, q. s.			

M. Ft. pilulæ No. xx. Sig.: Two pills twice a day.

Iodolene, a compound of iodol and albumin, contains about 10 per cent. of the former preparation. It is said to possess the antisyphilitic properties of the iodids and is more lasting in its effect, as it is more slowly eliminated. It may be given in doses ranging from 20 to 30 grains (1 20-2.00) repeated four or five times a day.

Iodipin, which is a combination of iodin in oil of sesame, is one of the best substitutes for the iodids, as it contains about 10 per cent. of iodin. It is said by the author not to be broken up in the stomach, but the iodin is liberated by the intestinal juices or, according to some authors, absorbed unchanged, and liberation takes place in the tissues. Consequently, its effects, as in the case of iodolene, are very much prolonged. This preparation produces no gastric disturbance and gives no symptoms of iodism. It is absorbed very rapidly by the system, as it has been detected in the urine within fifteen minutes after its administration by the mouth, but it has rarely been detected in the feces, which fact shows that it is practically all taken up by the system.

It is recommended in all the diseases in which potassium iodid is indicated, as in syphilis, asthma, neuralgia, arterio-sclerosis, etc. It is best to prescribe it in the form of an emulsion, as follows:

℞.	Iodipin	℥ii	60	
	Pulv. acaciæ	℥i	30	
	Aq. menth. pip.	℥iii	90	
	Syrupi simp.	℥i	30	

M. Ft. emulsio. Sig : One to two teaspoonfuls at a dose.

"Merck's Archives" recommends its administration in the following form:

℞.	Iodipin (10 per cent.)	℥iii	90	
	Yolks of two eggs			
	Pulv. cacao	ʒi	4	
	Sacchari	ʒii	8	
	Olei cinnamomi	m. ii		12

M. Sig.: One to two teaspoonfuls two or three times a day.

It is frequently given in the form of a hypodermic injection in doses ranging from 20 to 40 minims. The preparation must be placed in warm water previous to injecting, as the oil is too thick for hypodermic use when cold. It serves as a good test of the motor power of the stomach, as it is not absorbed by the stomach.

Medicolegal.

Medical Attendance on Husband a Family Necessity.—The Supreme Court of Nebraska holds, on rehearing, in the case of Leake vs. Lucas, that the husband, while living with his wife, is part of the family, and medical attendance of which he stands in need is a family necessity, within the meaning of section 1 of chapter 53 of the Compiled Statutes of Nebraska, which makes the unexempt property of a married woman liable for the payment of all debts contracted for necessaries furnished her family after execution against the husband for such indebtedness has been returned unsatisfied for want of property. And it holds that where medical attendance is furnished the husband under the circumstances above stated, and while the family are residing in Nebraska, and the family afterward remove to a sister state, a judgment against the husband in the state to which he has removed, and the return of an execution unsatisfied, is a sufficient compliance with the Nebraska statute to entitle the creditor to proceed against the wife (in Nebraska) for the collection of his demand.

Privilege Can Not Be Waived by Widow.—Section 834 of the New York Code of Civil Procedure provides that, "a person duly authorized to practice medicine or surgery shall not be allowed to disclose any information which he acquired in attending a patient in a professional capacity, which was necessary to enable him to act in that capacity." Section 836 provides that, "a physician or surgeon may, on the trial or examination, disclose any information as to the mental or physical condition of patients who are deceased which he acquires in attending such patient professionally, . . . when the provisions of section 834 have been expressly waived on such trial or examination by the personal representatives of the deceased." The words "personal representatives," as used in section 836, the First Appellate Division of the Supreme Court of New York holds, in the case of Beil vs. Supreme Lodge, Knights of Honor, apply only to executors and administrators. Consequently, where a widow was seeking to recover on a mutual benefit certificate made payable to her, but which she could not do under the terms thereof without proving that at the time her husband committed suicide he was in a state of delirium, resulting from illness, she was not entitled to call as a witness therefor the physician who attended him at or immediately prior to the time of his death, she not having the power to waive the prohibitions of section 834, not being the personal representative of the deceased within the meaning of section 836.

Utilizing Refuse from Consumptive Sanitarium.—The Third Appellate Division of the Supreme Court of New York says that the gist of the crime of which there was a conviction in the case of People vs Van Fradenburgh, was the disobedience of a lawful order of a board of health. Unless, then, the order disobeyed was one lawfully made by the board of health, the accused had been guilty of no crime. The order was one forbidding him from drawing into the corporate limits of the village any more refuse from the table and kitchen of a sanitarium for consumptives, which he had been collecting for feed for his chickens and hogs. There was no proof that this refuse from the sanitarium for consumptives was any more dangerous to the community when exposed than the refuse from any hotel, and the court says that it can not assume such to be the fact in sustaining this conviction. Has the board of health, then, the right to forbid a person from bringing into the village refuse from a hotel or any other public house? the court asks. Under the evidence in this case, it says, such refuse, while it is fresh, is wholesome food for hogs and fowls. The menace to the public health lies in permitting it to remain until it decays and throws off a stench which is prejudicial to the comfort of the community, if not to its health. As long, therefore, as the mere bringing into the community of fresh refuse from a public place has in it no element of threatened danger to the public health or comfort, the court is unable to see by what authority the board of health is permitted to prohibit the same. For this reason, it is added, the people have failed to prove the commission of a crime, and the judgment of conviction must be reversed.

County of Legal Residence Must Pay for Quarantine.—Section 7059 of the General Statutes of Minnesota of 1894, which provides for quarantine in case of smallpox, or other contagious disease dangerous to the public health, makes the expense a charge on the county in which the person has a "legal settlement," if he, his parents, guardian or master be not able to pay therefor. In the case of the Town of Louriston vs. Board of Commissioners of Swift County, a man and his family had resided in a county continuously for more than one year, and then moved to an adjoining county and became residents thereof. Then, inside of a month or so, some of the members of the family were taken sick with smallpox, and the board of health of the town caused the family to be quarantined and cared for. They never had been paupers or a public charge, but were unable to pay the expenses connected with their confinement and treatment. The town sued the county in which they had formerly resided for the expenses connected with their quarantine, care and treatment. But the Supreme Court of Minnesota holds that county was not liable, under section 7059 above referred to, for the reason that the family had acquired a legal residence in the other county at the time the expense was incurred. It says that the quarantine of those attacked with the disease, their care and maintenance, is an incident to the control of the contagion, and it naturally follows that if such persons are at the time residents of the county, such county is to bear the necessary expense of their care, provided the people themselves, or their relatives and representatives, are unable to do so. These acts are independent of and have no relation to the poor laws, except when the persons stricken with the disease were paupers or dependents while still residents of the former county The words "legal settlement" are synonymous with "legal residence."

What Constitutes "Sound Health."—In the case of Packard vs. Metropolitan Insurance Company the policy sued on contained a provision "that no obligation is assumed by the company prior to the date hereof, nor unless on said date the insured is alive and in sound health." The Supreme Court of New Hampshire says that it must be presumed that the parties intended by this provision what the words used by them ordinarily signify in common speech. What was meant by the words "sound health" was, evidently, not perfect health. "We are all born with the seeds of mortality in us." No definition can be given to these words that will apply in all cases. A mere temporary indisposition or ailment would not ordinarily be regarded as rendering the health unsound, within the meaning of these words when used in an insurance contract. Spe ing generally, they mean the absence of any vice in the constitution, and of any disease of the serious nature, that have a direct tendency to shorten life; the absence of a condition of health that is commonly regarded as disease, in contradistinction to a temporary ailment or indisposition. Whether, in a given case, a person is of sound health, must, of course, depend on the circumstances of the case. The insured in this case was a boy of 10 years of age. After he was examined by the company's physician, and before the date of the policy, he "fell sick of a disease of the heart," from which he died within six months. Although the disease was one which it was said was not infrequent among children, and is frequently outgrown, it could not reasonably, the court says, be regarded as a temporary ailment, or as not of a serious nature. A person having such a disease would not be regarded as in sound health. The fact that the boy's mother, who was suing, was not aware of the nature of the disease, and that its nature was undiscoverable except by a physician, did not prevent it from rendering the boy's health unsound. Undoubtedly, the testimony of the mother and others that the boy appeared to be in good health would be competent evidence on the issue of soundness, but it would not be conclusive. The testimony of physicians concerning the condition of his health, discovered by their examinations of him, would also be competent. If the boy was sick with consumption at the date of the policy, no one would say that he was in sound health

April 11.

1 *Some Problems in the Major Surgery of the Kidneys, with a Report of Cases. Joseph A. Blake.
2 *An Operation for Paronychia. Sinclair Tousey.
3 *The Geographic Distribution of Uncinariasis in the United States. William R. Stone.
4 *Report of a Case of One-Sided Dislocation of the Mandible. Reduced by a Novel Manipulation. Frank Woodbury.
5 Eye Affections Complicating and Resulting from Rheumatism. Ralph Opdyke.

1. **Kidney Surgery.**—Blake's paper is largely a report of cases, but he points out the advantages of nephrectomy over nephrotomy in pyonephrosis and hydronephrosis, allowing that the other kidney is in a good condition, and illustrates his points by cases. The dangers of so-called conservative surgery, namely, nephrolithotomy and pyelolithotomy in infected kidneys, are, he thinks, markedly emphasized by statistics, especially those of Israel.

2. **Paronychia.**—The operation described by Tousey consists in separating the attachment of the cuticle to the dorsal or exposed surface of the nail to a sufficient extent to permit the escape of the pus and the introduction of a stick of nitrate of silver to disinfect the sulcus. Its advantages over removal of the nail are simplicity and painlessness.

3. **Uncinariasis.**—Stone finds that only about 38 cases have actually been reported in this country, and at least 18 of them were contracted outside the United States. This discovery by Stiles of *Uncinaria americana* is, however, of importance, and it appears from the testimony of Dr. A. J. Smith of the University of Texas that about 8 per cent of the students there examined were infected with the parasite.

4. **Jaw Dislocation.**—Woodbury reports a case of onesided dislocation in which he replaced the mandible with the following manipulation: Seizing the ramus and angle of the bone with the left hand, he placed his thumb in front of the coronoid process. While pressing the bone downward and backward he asked the patient to gently open and close the mouth several times and then, at a time when the mouth was nearly closed, acting under impulse, he struck the left side of the chin a sudden gentle blow with the knuckles of his right half-closed hand. The return of the condyle to its place was announced by an audible click, to the great satisfaction of the patient. He thinks the gentle motions of opening and closing the mouth worked the condyle gradually back, and the sudden application of force took the muscles by surprise while they were, so to speak, off their guard, and the condyle with its articular cartilage slipped over the obstruction into the glenoid fossa, before the muscles had time to contract. He thinks the method will be useful in cases where the dislocation is confined to one side.

6 *The Technic of Nephropexy, with Special Reference to a Method of Attaching the Kidney as Nearly as Possible in Its Normal Position. Ramon Guiteras.
7 *Intranasal Obstruction and Its Treatment. H. Hoyle Butts.
8 *Cases of Morphinism in Which the Drug Was Immediately Withdrawn. Margaret S. Halleck.
9 *Bronchopneumonia. Joseph N. Study.
10 *The X-Ray and the Finsen Light in the Treatment of Lupus. A. D. Rockwell.
11 *The Treatment of Ringworm. George T. Jackson.

6. **Nephropexy.**—Guiteras outlines the various methods employed and gives his own technic. He denudes but one-half of the posterior surface of the kidney, that nearest the convexity, leaving the anterior surface intact. He then passes his sutures through and under the reflected capsule in such a way that they hold the organ securely during the formation of adhesions that goes on after the operation, and ties his sutures over the muscles and fasciæ in such a way as to bring the kidney into close apposition with the parietes, as nearly as possible at the normal level and in its normal horizontal angle, with the convex border pointing outward and slightly backward. The paper ends with an extensive bibliography on the subject.

7. **Nasal Obstruction.**—The various causes of nasal obstruction and the means of their relief are described by Butts. He believes in cases of hypertrophic rhinitis that there is nothing equal to the judicious application of the electrocautery for obstruction or hypertrophic tissue. In case of septal spurs he would remove them when they impair the respiratory function and whenever they impede drainage from accessory sinuses or nasal fossæ, or when they are in contact with opposing structures. For deformities of the cartilaginous septum he believes in the Asch operation. Septal abscess and nasal myxomata are also described, and he gives the technic for various operations.

8. **Morphinism.**—Five cases are reported of the rapid cure of the morphin habit by the use of hyoscin and strychnin injections, the former in doses of 1/200 of a grain, the latter 1/60 of a grain, with codein sulphate ¼ of a grain. Several cases are reported, some of opium smokers and others who had taken it by the mouth or hypodermically for seven to ten years. Halleck believes this method is better than the gradual reduction. Strychnin stimulates while the morphin is being eliminated, while the nausea, restlessness, insomnia and pain are cared for by the hyosin and codein. In the cases reported there seems to have been very little suffering from the rapid treatment, which lasted from one to five or six days.

9. **Bronchopneumonia.**—Study believes in the contagiousness of this condition, and would treat it by placing the child in the best conditions of light, ventilation and temperature, using turpentine and lard or camphorated oil; calomel to move the bowels, opium to quiet, in the smallest possible dose, and hydroptherapy as a rule for the high temperature, keeping up, of course, good nutrition by proper diet and nursing if the child is of the proper age.

10. **Lupus.**—Rockwell briefly reports a case in which a certain amount of benefit was derived from the Finsen light treatment, and the condition remained stationary, but was later cured by the use of *x*-rays. He questions whether this experience might not have been reversed in some cases from idiosyncrasy, etc. The question of the difference between actinic and *x*-rays is an interesting and important one in which the personal equation must often be the determining factor.

11. **Ring-Worm.**—The reason of the intractability of ring-worm of the scalp and beard is that the fungus grows down into the hair follicles, which can not be reached by the ordinary remedies. In looking for a suitable excipient, goose grease appeared to Jackson as about what he wanted. He found that a dram or more of the crystals of iodin added to an ounce of

goose grease will make a most effective remedy for ringworm. He applies it twice a day until it produces a reaction, and then once a day. In two or three weeks the hair falls out of the patch, which becomes bald for a time. After a time the hair grows in and the patch is well. If there is too much reaction, with swelling, the remedy may be suspended for a few days and salicylated oil of a 3 per cent. strength used. As soon as the reaction subsides the remedy should be used again. This method has been practiced in the Vanderbilt Clinic with good results.

19 How Can the Standard of the Medical Profession Best Be Raised? George V. N. Dearborn.

13. Degeneration of the Erythrocyte.—After an elaborate description of the changes which occur in the red cells in various conditions of disease, Da Costa summarizes as follows:

1. The viscosity of the erythrocytes is influenced by cellular and plasma alterations, the nature of which is obscure. The viscosity is exaggerated by the direct influence of various toxic agencies, and is diminished in many anemic states. This phase of cellular pathology is interesting from an experimental point of view, rather than as a finding of clinical application.

2. Simple decoloration illustrates the earliest retrograde change affecting the erythrocytes, and its intensity generally corresponds to the severity of the anemic process by which it is excited. The change may exist alone, as in the milder forms of anemia, or it may be combined with graver necrotic degeneration of the cells, in anemias of greater severity.

3. Deformities of shape and size are common to all pathologic blood, the degree to which such changes develop being related to the intensity of the blood impoverishment. Megalocytosis is a more serious sign than microcytosis.

4. Atypical staining of the erythrocytes betrays an impairment of function, and, as a rule, is found most commonly in corpuscles whose hemoglobin content is subnormal. It is most striking in anemias of the primary type.

5. The prevalence of megaloblasts indicates a fetal reversion of the bone marrow, and stamps the blood changes as pernicious, except in the anemias symptomatic of *Bothrioccphalus latus* infection and of nitrobenzol poisoning. The presence of megaloblasts indicate a severe anemia, but not necessarily one of fatal outcome.

6. Granular basophilia, whatever may be its exact origin, should be interpreted as a sign of degeneration. It is a constant blood finding in but a single condition—lead poisoning—but is associated with many diseases involving a variable degree of blood deterioration. The experimental basophilia excited by the administration of preparations of hemoglobin warrants a doubt as to the wisdom of using such medicaments as substitutes for iron in the treatment of anemia.

14. Cicatricial Contractures.—Traver reports a case where extensive cicatricial contractures of the upper extremity were cured by denudation of a portion of the cicatrix and substitution of a flap taken from the side of the chest. Successive operations by this method made a useless arm a practically normal functionating member. A full understanding of the article requires seeing the diagrams which accompany it.

15 Glycerol of Iodin.—Williams calls attention to the value of glycerin as an excipient for iodin, instead of alcohol, for local application. It has the advantage of leaving no stain on the skin and producing only slight local irritation while absorption is more complete. It can not be used as freely as the tincture because it produces symptoms of iodism more quickly.

23 *A Plea for the Use of Less Drugs in the Treatment of Typhoid Fever. J. K. P. Bowen.
24 *The Postorbital Limbus: A Formation Occasionally Met with at the Base of the Human Brain. Edward A. Spitzka.

21. Croupous Pneumonia.—Pneumonia is a self-limited disease tending to recovery, but varying under different circumstances in its severity and the effects of treatment. It is rare, Bradfute claims, in the normal individual. In nearly every case he thinks there is some radical defect, infection or some accompanying pathologic condition which serves to promote the growth of the germ. The pneumococcus alone is not always responsible. The influenza bacillus has been observed, and secondary infection may occur with the staphylococcus or streptococcus. It is not a systemic disease, but a localized infection with secondary systemic disorders due to exaggerated reflex influence and toxemia, and while, as a morbid condition, it is simple and free from obscurity, the indications for therapeutic measures are complex. We should not merely treat the symptoms, but treat the general pathologic state. In the regular typical cases without complications there should be no drug employed that would weaken the vital resistance. The coal tar preparations are especially unscientific, and he particularly protests against the use of digitalis. In cases in which it is necessary to control the abnormal circulatory movement as quickly as possible, he would give aconite, which, however, should be used with great caution—dosage of one to two drops—and not given to the extent of reducing the cardiac beats to the normal rate. Its action should be eliminated at the proper time by strychnin, 1/20 of a grain dose if necessary. At the beginning of treatment the bowels should be opened by calomel, mild glycerin suppositories or a seidlitz powder. The principal drugs that are indicated in treatment are strychnin, codein, ammonium and alcohol, the first two as nerve stimulants; ammonium as a cardiac stimulant. Hydrotherapy is also advised for combating the temperature, and he would use it in the method of cold compresses after the Baruch plan, which he describes A rubber sheet to protect the bedding is spread beneath the patient and over this a blanket. A piece of heavy flannel folded to several thicknesses, long enough to encircle the trunk, with about six inches to lap over, is wrung out of cold water, applied snugly to the circumference of the thorax and fastened with safety pins. This is then covered with a piece of dry flannel or part of a blanket and allowed to remain from fifteen to thirty minutes, according to the frequency of applications. When the compress is removed the front and sides of the chest should be rubbed briskly with a soft towel for a few seconds and the thorax enveloped in dry flannel. If the temperature is very high and intractable, above 104 F., these compresses should be wrung out in ice water and applied every half hour until there is a fall. They should not be applied, however, when the rectal temperature is 103 F. or less, for any chilling of the body is to be avoided. He insists on the constant and frequent administration of nourishment by liquid food, six ounces of milk every two hours as a standard rule. The alimentary tract should be kept free from decomposing food. He advises 5 grains of naphthalin twice daily from time to time, keeping the bowels open with calomel and sodium phosphate. Alcohol should also be used as a food. Half an ounce of whisky every two hours is usually sufficient, but when an odor appears in the breath the drug should be stopped and in every case diminished in dosage at the earliest possible moment to avoid establishing the alcohol habit.

22. Incipient Tuberculosis.—Lewis points out the principal symptoms indicating a tuberculous process, no one alone being sufficient. He lays stress on the importance of temperature, pulse, usually increased in frequency, but decreased in force, cough which is constant early in the disease, loss of weight, dilatation of the pupil and a tendency to hoarseness without apparent cause. The physical signs and hemoptysis are not sufficiently reliable in the early stages. Sputum examinations frequently repeated are important, though he has seen patients who have never shown bacilli even to death, though postmortem and inoculation experiments proved the diagnosis He considers that there is some danger in the tuberculin test in spite of the experience reported by others. From his own observations and experience he thinks there are safer methods. Treatment is dwelt on in some detail. The importance of open air, watching the temperature range and regulating exercise accordingly, proper attention to nutrition without crowding the digestive organs, the use of strychnin in rather larger doses than ordinarily administered or in increasing doses up to 1/10 of a grain three times a day, then going back again to the initial dose. Arsenic is the next most important remedy, and he finds dimethyl arsenate of soda the most efficient in doses of ¼ to 1 grain three times a day. To relieve the cough he would give guaiacol with heroin. He has lost faith in creosote. Atropin, agaricin and picrotoxin are each efficient in relieving night sweats, but an alcohol bath and a rub down at bedtime is often excellent. Internally, alcoholic stimulants are not advised. For inhalation he would use soothing antiseptic vapors. Numerous remedies are recommended, he says, but an especially eligible combination is one of iodin, tincture of benzoin, oil of cinnamon, oil of eucalyptus and albolene. In conclusion he remarks that the cure of incipient pulmonary tuberculosis is not the elusive phantom that it was ten years ago.

23. **Typhoid Fever.**—From a general discussion of the subject, Bowen lays down the following treatment of typhoid, physiologic and medicinal:

1. Rest; maintain the horizontal position to save the heart strength and do not endanger the intestines if complicated by congestion, hemorrhage or perforation; regular change of position in weak patients. Cleanliness, plenty of pure air and light, cheerful, inviting and quiet surroundings, as far as possible. No food usually to be given during the period of anorexia or first week or ten days of fever; then given more freely, as the case may demand, usually from one to three pints of buttermilk daily, plenty of pure water; warm sponge bath with massage of skin and muscles, hot water to abdomen for pain, cold pack for hyperpyrexia and delirium in some cases. Mental rest, be specific and symptomatic, avoid negative directions to nervous patients. Psychotherapy, also, is an important factor in vasomotor disturbances, which effects normal metabolism and repair of lesions, as well as in the so called functional disturbances. Avoid showing any signs of overanxiety by word or act, if possible. Inspire confidence, if you can; if not, retire at once. Serumtherapy should be employed if ever discovered and proved.

2. No drugs as a routine, except external antiseptics and for mouth and nose and some complications. Calomel may be given in the beginning, if indicated by a pale, coated tongue and constipation. Atropin if evidence of much congestion of intestines and pale skin, but not to be continued long; atropin is also valuable in some cases of meteorism, as it may correct the atony of the muscular tissues of the intestines. Castor oil is the best laxative and usually the best remedy for meteorism, necrosis and ulceration, and to be used throughout the case. Turpentine internally for meteorism and externally with hot water to abdomen for pain, also in enemata. Avoid using too freely salines for distension of bowels with liquids or for congestion or in plethoric conditions. Diluted hydrochloric acid if tongue is pale and flabby. Morphin and atropin for sleeplessness in some cases; also for severe pain or hemorrhage or active delirium, but should be used cautiously. Strychnin may be indicated, especially during convalescence. Acetozone may be tried as a general antiseptic. Greater skill is required to carry out successfully a general physiological treatment than in the mere drug giving, and the successful application of these principles will depend much on the judgment and tact of the physician. Success in the healing art rests on the knowledge of the principles, and clinical experience.

24. **Postorbital Limbus.**—Spitzka describes a curved, welt-shaped eminence, lying in apposition with the temporal apex on the orbital surface, which is demarked from the rest of the orbital region by a more or less distinct incisure. He has found this in a native of Japan, in two brains of female Papuans and in the brain of a distinguished American scientist He has found it described nowhere else as far as he has been able to observe, excepting in a Laplander by Retzius, who speaks of it as a post-orbital gyrus.

New York Medical Journal.

29 *Methods Which Render Some Therapeutic Agents More Palatable. Samuel E. Earp.
30 The Management of Occipitoposterior Positions of the Presenting Head. (Continued.) Walter J. Cavanagh, Charles Norton Barney and George B. Twitchell.

25. **Intestinal Obstruction.**—Hernias are the most common causes of intestinal obstruction and should always be looked for. They are usually overlooked especially in cases of internal hernias. They may often occur without distension or particular discomfort, making the case exceedingly obscure. Harvie notes these points and reports a case of obstruction and autorelief by the passage of a very large gallstone. The most common form of chronic obstruction will be found to depend on some malignant growth. This is the principal subject of his article. As soon as the diagnosis is made, radical operation would seem advisable, even before the diagnosis is complete. Two cases are reported, both showing a gradual onset with well-marked clinical symptoms. The idea of surgical interference seems to have been ignored for a considerable time in both cases The operative histories showed the practicability and almost positive favorable outcome if early operation had been done.

26. **Silver Sulphoichthyolate.**—This substance, known also as ichthargan, has been studied by Wood, who finds that it is readily broken up by hydrochloric acid, and is, therefore, unabsorbable as the sulphoichthyolate in the stomach. Its toxic power seems to be very much less than that of silver nitrate, and it is less irritating. The harmlessness of large doses depends on the slowness of absorption. A number of experiments is reported and show that the action of the compound is similar, at least qualitatively, to that of other silver salts. It has the advantage over silver nitrate in that it is locally less irritant and decidedly less poisonous.

27. **Intubation.**—The concluding portion of Taylor's article is entirely given up to reports of cases.

29. **Unpalatable Drugs.**—Earp gives several points in regard to making unpalatable drugs less disagreeable to the patient and insists on the importance of this point. To give castor oil in one dose, perhaps the "castor oil sandwich" is the best method. In the bottom of a glass put a small quantity of glycerin, then the oil, and lastly a little sherry wine on top. Take at one draught. This will also apply to the single dose of cod liver oil. Soda water will also be effective. It will also do for Epsom salts, but the ordinary "soda pop" is better. Quinin is hard to disguise. The preferable method, according to Earp, is to give one grain of tannic acid to each three grains of quinin in a vehicle of syrup of tolu. The iodid and bromid of potassium and salicylic acid may be given in milk, which also prevents gastric irritation. If copaiba and turpentine are not used in gelatin capsule form, an emulsion flavored with gaultheria comes next in order. For chloral hydrate he thinks peppermint water better than cinnamon. Equal parts of peppermint water and simple syrup make a good solution for salicylate of sodium. Unless there is an objection to the intensely sweet taste, the syrup of glycyrrhiza answers best for sodium salicylate. After flushing the mouth with a little whiskey the medicinal oils may be taken immediately, and the disagreeable taste is not so perceptible. A few grains of table salt taken on the tongue will produce a copious flow of saliva, and then, if swallowed with medicine which has an objectionable taste, it may be somewhat disguised. Care should be taken as regards chemical incompatibility in these cases. If lemon ice is held in the mouth for only a moment, a teaspoonful of a preparation which would otherwise seem nauseous may be taken with very little unpleasant effect. When the secretions are inactive and the membranes parched and dry, bitter principles are apt to produce the very worst effect and leave an unpleasant aftertaste. Sometimes simply a drink of water will obviate this condition, or perhaps a lump of ice held in the mouth or water acidulated with dilute phosphoric acid, to be taken before the medicine. A combination of syrup of red raspberry and glycerin makes an unusually palatable vehicle. He also recommends sodium bicarbonate with salicylic acid and sodium salicylate.

Boston Medical and Surgical Journal.

31 *Dry Hot Air as a Therapeutic Agent, with Demonstration of the Body Treatment. Clarence Edward Skinner.
32 *The Rôle of Atmospheric Pressure in the Hip-Joint. Seabury W. Allen.
33 *The Doctor in the Navy. A. J. Nute.
34 A New Modification of Tarnier's Axis Traction-Rods. L. V. Friedman.
35 Death from a Single Vaginal Douche; Report of Two Cases. G. De N. Hough.
36 The Relative Frequency of Multiple Sclerosis. E. W. Taylor and J. W. Myer.

31. **Dry Hot-Air.**—Skinner reviews the uses of dry hot air in various disorders, first of all rheumatism, in which he finds it useful to give some salicylic compound as an adjunct. The hot-air applications cause relief of pain, shorten the duration of the disease, lessen the liability to cardiac involvement owing

to the rapid control obtained over the pathologic condition, prevent the danger of reinfection, lessen the amount of drug medication the patient is obliged to take, and in many cases intractable to other measures it is curative. When judiciously applied it is never productive of vicious after-effects. Sprains are also readily amenable to this agency. In many cases of arthritis deformans it is a valuable adjunct to treatment, if not a curative measure by itself. From six months to a year or more is usually required to produce a cure, but he has seen cases cured in a month. Pneumonia is another disorder in which this treatment is of value, as also in local septic infection, chronic and acute nephritis and a number of other diseases which he lists. It acts as a direct stimulant to cell metabolism in the part treated, and produces reflex local hyperemia which with stimulation of the trophic nerve supply results in increased nutrition. If hyperleucocytosis is not already present the number of leucocytes is rapidly increased from 15 to 20 per cent, though if it is present there may be no increase at all. The red blood cells are increased from 10 to 20 per cent. The quantity of urine passed is increased as well as the amount of excretion of urea. The mouth temperature rises from 1 to 5 F., the pulse is accelerated, respiration deepens, and the capillary areas become injected. Perspiration is markedly increased and more acid. The oxidation of effete matters and the general functional activity of every organ and tissue in the body is augmented without and subsequent reactionary debility. Skinner describes the technic and remarks as regards the criticism that the results are not permanent, that in cases in which the condition apparently came back after treatment, the thermal agent was not properly supported by later treatment.

32. **Atmospheric Pressure in the Hip Joint.**—Allen reviews the statements as to the atmospheric pressure in the cotyloid cavity and has experimented with cadavers, successively cutting the muscles, capsular ligament and cotyloid ligament. The results of his experiments are that what holds the bone together is primarily the cotyloid and secondarily the capsular ligaments (in life elasticity of the surrounding structures helping them out), and that the air pressure need not be considered.

33. **The Doctor in the Navy.**—Nute gives a general description of the methods of becoming an assistant physician in the Navy and the advantages of the service.

37 *X-Ray Phenomena and Phenomena Not Due to X-Rays. Percy Shields. For What Conditions and How Should the X-Rays Be Used? Edw. H. Shields.
38 Surgery of the Prostate, Pancreas, Diaphragm and Spleen. (Surgery of the Pancreas). B. Merrill Ricketts. (Continued.)

37. **The X, or Cathode Rays.**—According to Drs. Shields it is not the x-ray but the cathode ray which is curative in malignant disease. They summarize their statements as regards the phenomena due to the x-rays and those not due to this agent as follows:

1. Relief of pain is due to the action of a high-tension current and connected in no way with x or cathode rays.
2. Cathode rays are the therapeutically active agents in the treatment of disease.
3. Affections beneath the surface, as deep-seated carcinoma, are in no wise affected by x-rays or cathode rays.
4. The only phenomenon which can be ascribed to x-rays is their ability to penetrate thick opaque bodies.
5. Bactericidal properties of x and cathode rays are *nil*.

As regards the therapeutic uses and methods they offer the following:

1. Superficial growths, both benign and malignant, can be relieved and often cured by the escharotic effect of the cathode ray.
2. Any lesion of the skin which can be relieved or cured by causing a superficial sloughing constitutes an indication for the use of the cathode rays.
3. Neither the x-rays nor the cathode rays affect in any degree benign or malignant disease beneath the surface.
4. Diseases due to bacteria or fungi are not cured by the x- or cathode ray.
5. Painful neuralgic affections are usually benefited, sometimes permanently, by the use of the high-tension current, but the relief is in no way associated with the use of the x- or cathode rays.

39 Our Needs—The Ideal Physician. J. W. Grosvenor.
40 The Significance of Oxaluria. J. Bergen Ogden.
41 The Prognostic Significance of Albumin in the Urine. Edward W. Lambert.
42 *The Symptomatology of Colds. George F. Cott.
43 *The Treatment of Colds. A. Alexander Smith.

42. **Colds.**—Cott notices the symptoms to which patients give the name of colds and points out that they are never of primary origin. We should remove their cause and the patient will then be free from the symptoms described.

43. **Treatment of Colds.**—Taking the treatment as usually understood by the laity, Smith holds that bathing the upper extremities, even including the head, is a certain amount of protection against taking cold. He is a strong believer in the communicability of colds, and is confident that in many cases fatigue and exhaustion diminish the resistance and render the persons more liable. The first thing he does is to take the temperature, and if it is above 100 F. he insists on the patient remaining at home, and better still in bed, if only for two or three days, which in the end saves time and the patient is much more comfortable. He is also sure that the traditional and orthodox use of opium and quinin, not in very large doses, but say 5 gr. of quinin, with 10 gr. of Dover's powder, with possibly a hot drink and hot mustard foot bath are often efficacious Frequently no further treatment will be required. The almost universal habit of giving cathartics at the beginning of treatment is to be commended. He also mentions the rhinitis tablet which has been in vogue, consisting of quinin, camphor and belladonna. If these can be taken during the first six hours, a half-strength tablet every hour for six doses, and then once every three hours until six more have been taken, it will often break up the cold. If, however, the cold has already lasted twenty-four hours, he prefers to use other remedies. It is necessary to produce at least slight physiologic effects of the belladonna with these tablets. Another method he has found very satisfactory is alkali given at the earliest possible moment, a dram of bicarbonate of soda in half a glass of water, and repeating the dose in one hour. If after twenty-four hours the cold does not seem to be better, this alkaline dose should be repeated. The salicylates are often useful, and he has seen cases where the inhalation of camphor fumes, with a few drops internally, gave great relief. The combination of one of the coal tar preparations, preferably phenacetin or acetanilid in small doses, with quinin often proves very beneficial when the skin is dry and hot and there is stuffiness of the nose, with muscular pains and headache. They seem, however, to prolong convalescence. In the majority of simple catarrhal colds no treatment except attention to the simplest rules of hygiene is required. In colds of moderate severity with a tendency to an excess of mucopurulent secretion, he has found great benefit from the creosote preparations. Carbolic acid has disappointed him. In children small doses of tincture of aconite will often be found useful. He gives it in doses sufficiently small to allow its repetition every hour and prefers it to any of the disagreeable tasting preparations for children under twelve years of age. He does not believe in the local treatment of colds. If there is a special tendency to recurrence he has seen much benefit from the use of tincture of chlorid of iron for two or three days only in large doses. He uses in such cases twenty minims every two hours, but after the second day it produces severe headache and must be discontinued. Another agent of value is cod liver oil In convalescence it is often of the greatest service to produce an absolute cure, and often prevents recurrence. Where the patient will not take this he gives quinin in small doses or some of the vegetable bitters.

50 A Case of Pneumonia, Probably Due to Streptococcus Infection. Walter L. Carr.
51 A Case of Retropharyngeal Adenitis and Abscess; Extreme Malnutrition; Recovery. John J. Cotter.

44. **Tuberculous Peritonitis.**—Guthrie finds that in 41 cases of tuberculous peritonitis treated at the Paddington Green Children's Hospital 14 underwent laparotomies and 7 of these died, while of the remaining 27 treated medicinally, only 4 were fatal. He says that as regards medicinal treatment we can not kill the tubercle bacillus. Arsenic might possibly affect the course of tuberculous peritonitis, but he knows of no other drug. We have chiefly to treat the symptoms. The patient is relieved of pain by rest in bed and local applications. Flatulency and indigestion need a careful diet. Diarrhea needs no active treatment unless profuse. A loaded rectum should be cleared by enemata rather than a purgative, but an occasional dose of castor oil or compound licorice powder may be given with no evidence of ulceration. We must remember, however, that ulceration may exist without such evidence. For ascites there is a question whether diuretics are indicated, but they can hardly be recommended as a routine practice. Vomiting is seldom excessive unless intestinal obstruction occurs, and then surgical aid is to be invoked. It is seldom necessary to have the diet entirely fluid. In every case rest in bed, at least in the early stages, is essential. The medicinal treatment consists in simply keeping the patient at rest, giving abundant and nutritious diet, relief of incidental symptoms as they arise, and the advantages of open country air. For ascites in acute cases, unless fluid produces great distention and distress, it is inadvisable to interfere, for if removed it will speedily reaccumulate In chronic cases where there is no tendency to subside, it should be withdrawn. Guthrie's theory is that laparotomy is beneficial in tuberculous peritonitis simply because it lets out the fluid. Dry cases without complications would recover equally well if let alone.

45.—This article appeared elsewhere. See The Journal of April 18, ¶57, p. 1106.

46. **Milk.**—Brown summarizes his conclusions on the subject of Pasteurized or sterilized milk: Sterilization at 212 F. is of great value because of its unversal practicability. Pasteurization at a temperature of 140 to 158 F. in closed vessels for fifteen minutes is much better, though we must admit that the heating of milk sufficient to kill bacteria does impair its nutritive value to some extent. When obtainable, clean pure milk used raw is much better and there is a rising demand for it. It may be provided in all cities or towns of even moderate size if the profession will demand it.

49. **Croupous Pneumonia in Children.**—Jennings gives temperature charts of five cases of croupous pneumonia, showing the sudden drop of temperature on the second to the fourth day which has confused the diagnosis in many cases. With this drop of temperature there is no change in the respiration or pulse curve, but these both sharply rise at the end of the remission

American Journal of Insanity, Baltimore.

59 *On the Motor Cortex. Clarence B. Farrar.
60 A Case of Metastatic Adrenal Tumors in the Left Midfrontal and Ascending Frontal Convolutions. Walter Channing and Wallace Knowlton.

52. **The Insane in Brazil.**—Kidder gives an account of the principal hospitals as he has observed them at Rio Janeiro, where the care of the insane seems to be according to the most modern scientific methods. In Bahia, on the other hand, the conditions are not so satisfactory, owing to the lack of proper legislation on the subject. The private institutions also in Rio Janeiro are in a creditable condition. In a very large part of the territory there is but little done. Away from the great centers of the population, removal of insane persons to central institutions is practically impossible owing to the expense. The death rate is large, but this is chiefly due to the tardiness in commitment, so that many patients are in a hopeless condition when taken to the hospital. Popular education will have to be depended on to correct this fault. There are also many grave somatic diseases due to the tropical climate which also increase the death rate.

53. **Nerve Degeneration.**—Coriat has elaborately examined the cerebrospinal fluid in a number of cases, including some 14 of paresis, others of melancholia, dementia precox, senile dementia, toxic delirium, alcoholic insanity, etc. He finds cholin present in the fluid in all the paretics and in several of the other cases. It is absent, however, in some cases of melancholia, toxic delirium, senile dementia, alcoholism, epilepsy and dementia precox. In a total of 34 cases it was absent in 11, present in 23. In one case it was also demonstrated in the blood, and in 6 cases of paresis it was found both in the fluid and in the brain tissue. He considers that the findings furnish a safe guide for the differential diagnosis between organic and functional nervous and mental disorders, which can be utilized during life by the method of lumbar puncture. Cholin seems to be present at any period of myelin degeneration.

54. **Dermatoses of the Insane.**—In 1,000 cases of insanity, nearly one-half of these terminal dements, 146 cases of pure skin disease were found, most of them in the dement cases. In some of the latter the disorder was from external causes and contracted before entering the institution. Winfield criticises the statements of alienists regarding cutaneous stigmata. He thinks their remarks in regard to telangiectasis and moles should be amended, though, in fact, such conditions are among the more frequent. Atrophy of the skin and hypertrichosis were the two other disorders most frequently found, and chiefly in terminal dements. The majority of cases occurred in females. The eight men thus marked had thin and coarse beards, but their bodies were thickly covered with hair, especially over the spine. Twenty of the women had a copious growth of thick stiff hairs on their lips and chins. In one case this symptom appeared during an attack of melancholia and disappeared on recovery. The statements made as regards a distinctive odor of the insane should be eliminated, he says, from text-books on insanity. Under modern cleanly treatment there is no cause for such a symptom to exist.

55. **Dementia Precox.**—In the case reported by Dunton, the autopsy showed slight cell changes in the brain, generally distributed, though most marked in the first frontal convolution. The cells showed central chromolysis, perhaps a little pale yellow pigmentation, atrophy, dislocation and swelling of the nucleus, folding of the nuclear membrane and an endonucleolus. The deeper layers were most affected as a rule. The motor cells showed very slight changes There was a slight increase of neuroglia nuclei. Phagocytosis was well marked, and there was considerable cell disintegration. There was no change in the medullated fibers, and no marked vascular changes. While no positive inference can be drawn from the findings, he thinks they may be suggestive in connection with further work.

58. **Acute Paresis.**—From a study of the cases here reported, Paton and Rusk conclude that it is probable that this type is less frequent than has been commonly supposed. To place a case under this class we should not only exclude the subacute or chronic initial period, but the acuteness or chronicity of the pathologic process in the central nervous system must be carefully considered. The pathology is not characteristic. A general and not localized disappearance of the fibers from all cortical areas was observed, but it is not pathognomonic. The neuroglia showed an increase of the cellular elements, with little if any increase of the fibers. There was some overfilling of the blood vessels. Many round nuclei were found in the perivascular spaces. Numbers of plasma cells were observed in the cortex. The character of the changes in the various organs, as well as in the central nervous system, suggested a general intoxication. The vascular changes of the

cortex were not sufficient to account for the degeneration of the nerve elements.

59. **The Motor Cortex.**—Farrar's article is a critical review and summary of the literature on cerebral localizations. He points out that the motor cortex occupies the middle region of the hemispheres, is the earliest to functionate, and the central sulcus gives increased room for its developing elements. This area has been gradually narrowed, until now the post-central gyrus is practically excluded. Cajal has described a specific fiber distribution in the precentral convolution, which he thinks serves to differentiate it as the motor type of cortex. That a motor type exists is proven; it is characterized by its unusual width dependent on the marked development of the medium-sized pyramidal cell layer containing the specific plexus of Cajal, by the absence of a clearly-defined granular zone, and by the presence of giant cells in the sixth layer with thicker and denser radial bundles and a richer development of the overlying tangential fibers, which are of maximum density in those parts which contain the greatest number of giant cells. Beyond the limits of the motor area in all directions, one observes a gradual change in the cortical type, the third layer becoming narrower, the fifth wider, and the specific elements of the sixth disappearing. This is recognizing eight layers of the cortex, according to Cajal. The paracentral lobe represents both types of the cortex, the transition taking place below the extremity of the fissure of Rolando, although no surface marking determines the boundary.

61 A Fatal Case of Schönlein's Disease. William T. Watson.
62 *The Prognosis of Chronic Otorrhea. H. O. Reik.
63 *Perforating Wounds of the Crystalline Lens. Geo. A. Fleming.

62. ***Chronic Otorrhea.***—*The object of Reik's paper is to point* out that the cure of chronic suppurative otitis media is not, by any means, as hopeless a matter as is often regarded, and to call attention to the recent methods. He thinks about one-half of the cases call for some surgical treatment, either major or minor, including among the latter removal of polyps and cauterization. In most instances ossicular necrosis exists and the removal of the diseased bones permits of cure through improved drainage and better cleansing of the tympanum. About 50 per cent. of the one-half requiring surgical operation will be relieved in this way. In the remainder the radical operation will have to be performed, and he thinks that, as the surgeon becomes more familiar with the technic, the 2 or 5 per cent. of cases now recognized as incurable will be still further diminished.

63. **Injuries of the Crystalline Lens.**—Fleming reports three cases, in all of which there was considerable inflammatory exudate involving at least one-third of the lens, yet the latter cleared up with recovery of the normal transparency and function.

64 *Reversals of Habitual Motions, Backward Pronunciation of Words, Lip Whisperings of the Insane, Sudden Failures of Volition, Repetition Impulses. S. Weir Mitchell.
65 A Case of Multiple Fibromata Confined to the Internal Plantar Nerve. Wm. J. Taylor and Wm. G. Spiller.
66 A Case of Myasthenia Gravis Complicated by Angioneurotic Edema. Theodore Diller.

64. **Reversal of Habit, etc.**—Mitchell's paper contains some interesting reports of cases of patients with cerebral disorders in which the symptoms were the complete reversal of the usual habitual actions. He mentions one patient with tumor of the brain who pronounced all his words backward, and it was only by close study that this was discovered. Such expressions as "dog ho" and "tacym" were finally interpreted as "Oh! God," and "my cat." There were other cases where paraphasia took the form of the exact reversal of the sense intended. He also notes some peculiar obsessions, many of which seem to have escaped study.

70 Uremia in the Process of Childbearing. Earl Bigham.
71 *Enteroptosis and Pregnancy. Charles D. Aaron.

67. **Pilocarpin in Catarrhal Deafness.**—Gillman has used intratympanic injections of pilocarpin in many cases of catarrhal deafness from otitis, first introducing the eustachian catheter and forcing the solution into the middle ear by the Politzer bag. He reports two cases, and concludes that it is absolutely effective in certain instances, together with allied treatment; in others it may simply avert the worst consequences, while, perhaps, in the larger number it is ineffective.

71. **Enteroptosis in Pregnancy.**—Aaron reports two cases of enteroptosis which were largely benefited by pregnancy. He remarks, in conclusion, that dispensing with the abdominal bandage, according to the new method, predisposes to enteroptosis, while the ordinary pregnancy assists its cure, and patients in this condition need not hesitate to become pregnant. The disagreeable symptoms of the condition seem to disappear during the pregnancy, and keeping the patient in bed after the delivery and applying an effective bandage is very helpful in its permanent cure, while early convalescence and insufficient support have the opposite effect.

77 A New Mechanical Saw for Intra-Nasal Operations. Edwin Pynchon.
78 A New Postnasal Applicator. J. C. Buckwalter.

72. ***The Sphenoidal Sinus.***—Mosher's article is an elaborate, illustrated description of the anatomy of the sphenoidal sinus, and he gives the measurements by the nasal route and the antrum, favoring the latter as a means of approaching this cavity. Through the nose, the lower anterior edge of the face of the sphenoid, as he measures it, is 2¼ inches, and from the middle of the canine fossa, 1½ to 2 inches. The route to the sphenoid by way of the antrum is, therefore, the shortest and most direct. By it the operator has two guides to the lower edge of the sphenoid, the finger in the mouth at the upper rim of the choanæ and the level given by the incision made from the ostium backward through the membranous area. By this route three of the four accessory sinuses of one side can be opened up. The sphenoid sinus of the opposite side can also be opened and, experimentally on the cadaver, in many cases, the frontal sinus. In combined empyemata of the antrum, the ethmoid region and the sphenoid, he thinks this method is the one for reaching the parts. The paper concludes with a very extensive bibliography.

74. **The Cold Snare in Tonsillotomy.**—Myers has used the cold snare for some time, and believes it to be the best instrument for the removal of the tonsils. It is adapted to any tonsils that require removal; the half buried, flattened and hard tonsils which no tonsillotome would reach, are very readily removed by the properly constructed snare, by the additional use of a small tenaculum to draw the tonsil from its bed into the loop. Under local anesthesia it is not a severe operation, and he has never seen the tonsil too hard to be severed. He passes the loop over the tonsil, packing it in with the tenaculum, then slightly contracts the loop to test its hold, then the tenaculum is dropped and both hands are used to close the loop.

75. **Hemorrhage After Tonsillotomy.**—Bulson reports a case of alarming secondary hemorrhage, which he had considered as a rare occurrence, but which he now thinks is a very possible one. The child may be swallowing blood for some time before the hemorrhage is detected. He thinks it was an error of judgment in his case not to pack the post-nasal space before or

immediately after the hypodermoclysis which was used in the treatment, as the secondary hemorrhage caused by the raising of the blood pressure came from that region. Transfusion or saline injection should not be given without knowing that all the bleeding parts are under control.

85 Hemorrhage from the Eye After Cataract Extraction. Swan W. Burnett.

81. **Changes in Refraction.**—Risley remarks that he originally believed that static refraction of the eye was a fixed of immutable quantity, and he was inclined to consider differences which he found from those of other observers due to an error of observation. He reports four cases, however, where a marked change in refraction occurred under his own observation, and remarks that we should have more charity with the early work of others and ourselves in such cases. While he still believes that in the vast majority of cases no change occurs, there are numerous exceptions to the rule.

87 *Gastric Muscle Fatigue and Dilatation. Fenton B. Turck.
88 *The Regulation of Barber Shops. W. E. Hartman.
89 Fundus Lesions and Their Relation to General Diseases. (Concluded.) George F. Suker.

86. **Rheumatism.**—Nolen insists that the heart is involved in the vast majority of cases of rheumatism, chiefly by endocarditis; pericarditis is next in frequency, and, in this case, more often in the male. The younger the patient and the more severe the attack, the greater the liability to heart complications. She insists on the importance of early recognition of cardiac involvement by daily systematic and thorough examinations, and, if it is detected, treatment by absolute rest.

87. **Gastric Myasthenia.**—Turck describes this condition, chiefly due to frequent overloading of the stomach. We should differentiate between gastric fatigue caused by excessive work, that caused by some toxin and that due to obstruction of the pylorus. He describes his method of treatment by gastric dilatation and disinfection with superheated air charged with oil of cloves, etc. He advocates this pneumatic gymnastics of the stomach, which he thinks has a powerful effect on the circulation not only of the sphlanchnic system, but also on the general circulation. It has been found, he says, in the less severe cases, that a few of these treatments combined with careful diet and the measures that would naturally be enforced will cause the stomach to empty itself normally, and such treatment, carried on over a somewhat protracted time, will result in a permanent cure. For the diet he would first use raw eggs and coagulated milk; later chopped meats and bran are added to the diet. A period of rest should be allowed between the times of feeding At the outset in many cases but one meal a day is allowed, followed by two meals daily for a long time.

88. **Barber-Shop Regulation.**—Hartman pleads for sanitation and disinfection of barber shops, care as to cleanliness, disinfection of tools, etc.

1 **Apparatus for Locating Bullets in Skull**—The main advantages of the simple apparatus presented are that it dispenses with calculations and the necessity for an assistant, and that the fluoroscope is placed between it and the subject Two long rods are mounted on a vertical standard They are slipped back to allow the interposition of the fluoroscope, and after the vacuum tube has been adjusted to cast a shadow of the bullet on the point of each rod in turn, the fluoroscope is removed, the rods slipped forward until they touch the skull, and the bullet is located at the intersection of the prolongation of their axes Trouvé's "alarm probe" has been modified in connection with this apparatus, so that, substituted for one of the rods it serves as a probe, gives warning when the bullet has been reached, and also seizes it when the foreign body can be withdrawn with the probe The apparatus is illustrated in the original

3 **Axillary Adenopathy in Incipient Tuberculosis of Lung**—Fernet calls attention to the information to be derived from examination of the glands in the axilla in incipient tuberculosis Enlarged movable glands, the size of a pea or larger, have usually coincided in his experience with a cervical adenopathy on the same side, and testified to the existence of some incipient tuberculous lesion in the corresponding lung These glandular lesions never give trouble and probably retrogress later, as he has never found them in later stages of the disease

4 **Text of the Antiliqueur, etc, Resolutions**—The Academie declares that all natural or artificial essences, without exception, as well as the extracted substances, incorporated with alcohol or wine, constitute dangerous and harmful beverages They are dangerous both on account of the essences and of the alcohol they contain, and they should be prohibited, or at least a prohibitory tax imposed The Academie calls particular attention to the danger of the "apéritifs," that is, the beverages with essences and alcohol taken on an empty stomach The fact that they are taken before meals renders their absorption more rapid and their toxicity more active The Academie also voted a resolution urging that effective measures be taken to diminish the number of dram shops These resolutions were passed on the request of the government, which applied to the Academie for advice in the matter, suggesting that two lists should be drawn up, one to include the dangerous essences and the other the least injurious The Academie decided that where all were harmful it was unwise to discriminate

6 **Antituberculosis Serum from Fowls**—The curative serum made by Viguier de Maillane from the serum of fowls was mentioned in THE JOURNAL of April 11, p 999 The technic of its preparation was given, but is not published in the "Bulletin," as the communication was referred to the tuberculosis committee

7 **Steam of Hydrogen Dioxid for Therapeutic Inhalations.**—Maget and Planté have found that enough of the oxygen is retained in the steam from boiling hydrogen dioxid to render it a valuable therapeutic agent They have applied it in veterinary practice and also on patients with chronic tuberculous laryngitis, and the improvement noted testified to the efficacy of the measure They found that a strength of 9 to 11 volumes gave 2 to 4 volumes in the distillate, but averaged 1 and 2

8 **Tuberculosis in Etiology of Mental and Nervous Diseases.**—Anglade and Chocraux believe that tuberculosis occurs in an excessive proportion in the antecedents or present condition of persons affected with mental or nervous diseases They call attention to the frequency of tuberculous parentage in mania and melancholia A subject with general paralysis, if not syphilitic, is almost inevitably tuberculous, and frequently both combined Epileptics, idiots, etc, often have a tuberculous taint or die tuberculous On the other hand, Anglade's method of staining the neuroglia has shown that epilepsy and imbecility coincide with an excess of neuroglia, and that this proliferation of neuroglia constitutes the true encephalitis of general paralysis and the pseudo encephalitis of mania and melancholia. He has also demonstrated that tuberculosis has toxins capable of inducing in an extreme degree this diffuse neuroglic reaction in both cortex and ependymis They consider, therefore, that tuberculosis may possibly be responsible for a large number of cases of mental and nervous disease It kills a certain part of the population and renders another part epileptic, insane, idiot or subject to some other mental or nervous affection, possibly by its action on the embryo Raymond, in presenting their communication, stated that he does not accept their conclusions as fully established, but still advises to bear in mind the possibility of tuberculosis in the pathogenesis of mental and nervous affections in general, although he doubts whether it will ever assume as important a place as that accorded to syphilis and alcoholism in the genesis of these affections

13 (No 12) *Chirurgie des grosses ascites F Lejars

10 **Behring's Suggestion for Vaccination of Infants Against Tuberculosis**—Cheinisse reviews all of Behring's communications on the subject of the immunization of human beings and cattle against tuberculosis, referred to in editorial in last issue He uses for cattle a culture of human tubercle bacilli on glycerinated serum, desiccated in a vacuum at ordinary temperature Of this desiccated culture 004 gm are injected into the jugular vein of a calf less than three months old, after the bacilli have been ground in a mortar and emulsified in 4 c c of a 1 per cent saline solution The amount injected is equivalent to 02 gm of a fresh culture, but the desiccation reduces the virulence of the bacilli A month later 01 gm of the same culture, but fresh, is injected in the same way. The animals are then immune and placed in the midst of infected herds for months to a year have shown no traces of tuberculosis when slaughtered As intravenous vaccination of infants is out of the question, Cheinisse hails as ripe with promise his suggestion, mentioned in our editorial, p 1083, that possibly equally favorable results might be obtained by feeding infants on milk from immunized cows

13 **Surgery of Large Ascites**—Lejars advocates laparotomy in all cases of extensive ascites of doubtful origin He describes a number of instructive cases The abdomen in one measured 94 cm at the umbilicus, but nothing abnormal was discovered at the laparotomy except adhesions between stomach and liver, possibly the result of an old, healed ulcer The ascites has not recurred since the adhesions were detached, and the patient has been in good health since He urges, in particular, early intervention in case of the ascites of cirrhosis, while it is yet time to accomplish good results After the liver has become seriously compromised little can be expected from omentopexy as a last resort He quotes, with approval, Harris' article in THE JOURNAL of May 3, 1902 In many cases supposed to be of a tuberculous or carcinomatous nature, the laparotomy will reveal the welcome suprise of some comparatively insignificant lesion He affirms that the well established fact of the benefit derived from a laparotomy in tuberculous peritonitis is by no means confined to the tuberculous form Every chronic peritonitis, whatever its nature, is susceptible of improvement from it In one case of diffuse carcinosis with extensive ascites of the abdomen the patient was remarkably improved by a laparotomy and drainage, and survived six months in comparative comfort. The surgeon in such cases should not attempt to disturb the conditions, but merely drain with strict asepsis, and general anesthesia is not necessary He has collected 78 cases in which Talma's operation was performed, but as it was done as a last resort, the proportion of 28 cured and 14 much improved does not represent the actual value of the intervention He has done it three times himself

16 *Ueber eine neue Anwendungsform (form of application) des Gelatose-Silber-Nitrats (Albargin-Höchst). Zur Behandlung der Dickdarmerkrankungen (affections of large intestine). W. N. Clemm.

14. Gastrocolic Carcinomatous Fistula.—Koch has had occasion to observe two cases of this condition in Erb's service at Heidelberg, and has collected 68 others. He tabulates the details of the 70 cases. The interval between the first symptoms of the fistula and death ranged from six days to two and a half years Not all were cancerous; in 20 per cent. an ordinary ulcus was the cause, tuberculosis in a few, and in one the fistula was congenital. The gastrocolic fistula may develop without any symptoms, as in Aron's case, in which edema of face and legs, an effusion in the abdominal cavity and pleura and the waxy complexion were the only clinical manifestations except weakness and loss of appetite. There had never been pains in the stomach, vomiting or fever, and yet the autopsy revealed a carcinoma with a broad fistula into the colon. Fecal vomiting is the most constant symptom, but it might be prevented by complete stenosis of the pylorus or by an unusually large fistula, both of which favor the occurrence of diarrhea with undigested food, lientery, which is the second most characteristic symptom. The third is the identity between the vomit and the diarrheic stools. Accessory symptoms are the rapid emaciation, excessive thirst, fecal odor of mouth and eructations. Another symptom is the abrupt cessation of long continued vomiting of food. If gastric juice can be detected in the stools the diagnosis is confirmed, as also flatus per rectum after inflating the stomach. Sometimes a metallic ringing and gurgling sound can be heard. A stained fluid injected under pressure into the rectum may be voided by the mouth, or fluid introduced by lavage of the stomach may be siphoned out through the rectum. Treatment can be only symptomatic, morphin and opium. Some have tried an artificial anus in the ascending colon or recommended partial resection of stomach and colon, but without results. One patient was conscious of the formation of the fistula, feeling as if something had burst.

16. Improved Silver Nitrate Treatment of Colitis Membranacea.—Clemm imagined that the non-irritating properties of the combination of gelatose and silver nitrate, called albargin, which have proved so useful in urology, might be equally effective in intestinal affections. Time has confirmed the correctness of this view. He substitutes it for the oil cure recommended by Fleiner and Kussmaul, and uses it for the same indications. He dissolves two albargin tablets of .2 gm. each in a little hot water and then stirs it into .25 liter of tepid water. This is injected into the rectum at night, to be retained, the buttocks raised or the subject lying on his left side, then turning on his abdomen and then on his right side. The first of these albargin injections may bring an enormous quantity of the membrane-like strips of mucus, but after this the membranes disappear from the stools with remarkable rapidity. The albargin reaches the diseased mucous membrane without irritating it in the slightest, thanks to its gelatose element, and then penetrates into the intercellular spaces, where the silver nitrate is liberated from the gelatose and acts directly on the inflamed goblet cells. If the nitrate alone were used, it would coagulate the albumin on the surface and induce irritation without the ability to penetrate into the depths. He describes 10 cases thus treated; in one instance, at least, the colitis membranacea had alternated with liver colic. All of the inconveniences of the oil treatment are avoided by these albargin injections, and they frequently succeed where the oil fails.

17. Marrow Lesions in Typhoid.—Fraenkel has discovered what he believes to be a constant accompaniment of typhoid infection, that is, multiple foci of necrosis with deposits of fibrin, scattered through the red bone marrow, with a special predilection for the vertebræ and ribs. These foci occur from the first week of the disease late into convalescence. They may spontaneously retrogress or may continue to progress and entail clinical manifestations. They explain Quincke's spondylitis typhosa, but are more correctly entitled typhoid osteomyelitis. Fraenkel found these lesions constantly in 13 typhoid cadavers, including one subject who had died from an intercurrent pneumonia. Of the number 6 were men from 17 to 43 years of age; 5 were women from 19 to 52, and 2 were children from 1 to 10. Death had occurred in the first week in 3; in the second in 4; in the third in 4; in the sixth in 1, and during a relapse in 1. They were never found in his examination of cases of diphtheria, scarlet fever, erysipelas, phlegmons, pneumonia nor peritonitis, but Chiari has observed a similar phenomenon in variola. He studied it on 22 cadavers, and published an account of it under the title osteomyelitis variolosa. His description differs from Fraenkel's, however, in the fact that he noticed occasionally evidences of inflammation and did not find traces of fibrin. The typhoid foci are distinguished by the complete absence of any tendency to inflammation or suppuration and the constant fibrin deposits best brought out with the Weigert fibrin stain. Typhoid bacilli were found constantly in the marrow in the 10 cases examined, with the other bacillus in cases of mixed infection.

18. Remote Results of Internal Treatment of Gastric Ulcer.—Schulz reviews the results in 184 cases treated at Kast's clinic at Breslau and 107 at Hamburg. Of this total of 291 cases, 165 were dismissed as cured and 95 much improved, 15 as unimproved, and 16 died. Treatment was by the Ziemssen-Leube method. It failed, therefore, in 11 per cent., while the mortality was 5.5 per cent. He has been able to obtain information of the late results in 157 cases from six months to twenty-four years after the course of internal treatment. Only 64 per cent. have been permanently cured. The number of the uncured has increased threefold, while the number of improved has diminished by 25 to 33 per cent., and the cures are not so complete as assumed at first. The immediate results are no criterion of what may be anticipated later, and the cases that are merely improved are liable to grow worse again. On the other hand, these statistics show that, in spite of only moderate success at first and in spite of recurrence, a cure may still be effected by internal treatment, and even without this in time. The patient should not be dismissed from treatment until a complete cure has been realized If improvement is not speedily obtained the possibility of complications should be borne in mind, and other measures should be considered. He gives in his statistics the condition at dismissal and when examined later of the different cases for better comparison.

19. Focal Symptoms of Acute Hydrocephalus in Adults.—Grober's patient was a woman, aged 24, whose husband was syphilitic. The affection developed and ran its course to a fatal termination in ten weeks. Potassium iodid was administered, but without benefit. The autopsy disclosed hydrops of the ventricles, but no meningitis nor tumor, as anticipated, merely an ependymitis granulosa. Among the symptoms observed were spasms in the right face, loss of sensibility in the right supraorbital region, paresis of the left facialis and hypoglossus, knee-jerk on right side exaggerated, choked disc and vomiting. He has found only two similar cases on record, all fatal. Lumbar puncture was done once, but alarming symptoms compelled its discontinuance, although the patient seemed easier afterward. In future he should institute vigorous specific antisyphilitic treatment and at least try the efficacy of repeated small lumbar punctures.

20. **Volvulus of Cecum and Ascending Colon.**—Wandel has noticed in examining 640 cadavers that in 10 per cent. the lower part of the cecum and ascending colon was freely movable from lack of the normal fixation. This exposes the individual to the danger of displacement of this part of the bowel and he has observed in the clinic 5 cases in which this occurred. The cadavers were those of 13 male and 15 female children, 22 men and 16 women. In his clinical cases the kinking or spiral twisting on the longitudinal axis or twisting on the mesentery occurred suddenly, usually from some muscular effort in which the trunk was stretched over backward, as in trying to hit a high ball in tennis. In some cases these attacks of recurring volvulus at long intervals dated from infancy, and there was generally a history of the failure of purgatives to relieve Frequently the colic is merely aggravated by them. During the colic the subjects usually find that standing very erect or bending forward will relieve the pain.

22. **Treatment of Typhoid Perforation with Ileostomy.**—Escher is so fortunate as to be able to report 3 patients cured out of 4 on whom he operated on account of peritonitis from perforation of the bowel in the course of typhoid fever. Three were very severe cases. The patients were from 8 to 19 years of age and the intervention was required at the end of the third or beginning of the fourth week. From twenty-two to eighty hours had elapsed after the first signs of perforation except in the case of a child of 8 in whom the acute symptoms had been noted for ten hours after a suspicious stage lasting seventy-two. In reviewing the literature he has found 22 cases reported as under 18 years and only about a quarter recovered after the operation, but some required a second intervention; 1 died in a relapse and 1 passed through a serious metastatic pyemia. These results demonstrate that children are no better subjects for operation in such cases than adults. He attributes his 75 per cent. of complete recoveries to his technic. He does not attempt to suture the perforation, but merely draws the perforated intestine to the wound and sutures the loop to the skin. This saves time and rests the inflamed gut below, but its chief benefit is that it wards off the dangers of the obstruction of the bowels, which is sure otherwise to follow the perforation from partial paralysis of the bowel or other cause. There is no meteorism when this is done, no stagnation of feces, and convalescence proceeds rapidly. On the other hand, the time required to suture the perforation is a great strain on the patient, while it acts directly contrary to Nature, which seeks to relieve the paralytic ileus by opening an outlet by way of the perforation. The artificial anus created by the ileostomy should be made in the perforation and in such a way as not to interfere with the draining tamponing of the peritoneum. In case the opening afforded by the perforation alone is not sufficient, ileostomy at any other point may be done. This fastening the perforated loop to the skin, supplemented by draining tamponade of the peritoneum, is the most certain means of prevention of further spread of the peritonitis. (See editorial in last issue.)

23. **Foreign Body in Air Passages.**—Kredel warns to have everything in readiness for tracheotomy before attempting instrumental extraction. He reports 5 cases. In 3 a bean and in 2 a nail had entered the air passages. In one case the child might have been saved by proper intervention, but the symptoms were ascribed to another casual cause. In one a swollen bean in the trachea acted like a valve, causing dyspnea during expiration, along with paralysis of the lungs. In another the nail stuck between the hyoid bone and epiglottis, holding down the latter.

24. **Pyogenic Action of Pneumococcus.**—Meyer has observed 24 cases of this nature. The pneumococcus has an especially pyogenic tendency in children, with a predilection for the serous membranes, but he has observed strumitis, abscesses in mouth and bones, periostitis, arthritis, peritonitis and general sepsis from its action.

32 Sur quelques particularités de la névralgie faciale et son traitement par l'electricité. A. Zimmern.

26. **The Fundus of the Eye in Paresis.**—In an examination of 51 paretics Keraval and Raviart find that the majority were males with notable lesions of the fundus, and in only those that were in remission were they lacking. In 7 advanced cases there were 5 of white papillary atrophy, one of gray atrophy and one of posterior sclerochoroiditis of both sides without myopia. A pale disc was observed in 13 paretics. In 22 others one segment of the papilla, external, internal, lower or upper, presented a soft (flou) appearance, vaguely margined. This is the preliminary stage of papillary atrophy No cases were found in women of these slow and long-continued types of ophthalmic lesions. An ophthalmic examination was confirmed in autopsies by microscopy, and even in the mild cases there was a papillary neuroretinitis presenting the same characters of diffuse meningoencephalitis; infiltration of the noble elements of the papilla and ophthalmic nerve by connective tissue cells, thickening of the connective tissue framework of the nerve, diffuse atrophy of the ganglion cells and nerve fibers of the retina and in the more advanced cases destruction of the nerve cells of the retina and production of papillary sclerosis.

29. **Contagion of Insanity.**—The name "folie à deux" should be supplanted by the more general designation of insanity by contagion and morbid suggestion. This last designation is based on the pathogeny of the disorder and has the advantage of comprehending in the same term cases of psychic phenomena which start from morbid suggestion and all the insanities of crowds. It is necessary to separate the codeliriants in all cases of contagious insanity. It is also necessary to consider from a medicolegal point of view the subjects of the passive imposed insanities as being in the suggestive state and consequently irresponsible so far as they are in that condition.

31. **Post-Operative Psychoses.**—Under the title of post-operative psychoses Picqué and Briand include practically only the disorders of the ideational sphere. Post-operative neurasthenia should be distinctly separated from them. In the group thus limited we may separate the toxic forms and consider them apart. If they are allied in a nosologic point of view, this is not the same in practice, and uniting of the two forms obscures the questions of prophylaxis, symptomatology, prognosis and treatment. The infectious insanities are the transitory forms which may recover spontaneously in hospitals or under surgical treatment. To send them to an asylum, as is often done, is to sequestrate them unnecessarily and take them away from their needed surgical aid. The true post-operative group on the other hand is permanent and can be treated only in the asylum. The pathogenicity of these insanities varies in the two groups. In the first the insanity is exclusively infectious and may be cured by suppression of the focus. There is no history of acquired predisposition of the nerve centers, but in the second this predisposition constitutes the principal active cause. It is more particularly a hereditary degenerative weakness. The authors insist on the importance of this separation and report a number of interesting illustrative cases.

35. **New Data in Physiology of Tendon Reflexes.**—Stcherbak has found that vibrations such as those produced by a tuning fork, are a specific stimulus to the deep nerve terminals involved in the production of the knee-jerk. A large tuning fork was screwed firm on a stout metal standard and set in motion by an electro-magnet, about 33 vibrations to the second. He applied to the standard the knee or other part of the animal to be tested, and thus made thirty-five tests on 16 rabbits. When the knee was applied, the knee-jerk was much exaggerated by the procedure. The vibrations were able to artificially "charge" the reflex apparatus with nerve energy, and percussion and passive movements were able to "uncharge" it afterward. Percussion and passive movements of the knee after the vibrations induced clonus of the knee or spasmodic trembling. These phenomena could likewise be induced by similar irritation of the other leg, exaggerating the crossed reflex. After an hour of the primary vibrations the spasmodic phenomena could be elicited as late as twenty-four days afterward by passive movements of the leg. The more intense the stimulus and the shorter the interval, the fewer passive movements were required. If the spinal cord was severed above the route of the patellar reflex, local application of the vibrations induced a durable, unilateral exaggeration of the knee-jerk, but no clonus nor tremor. Passive movements repeated even 4,300 times on one control animal never induced the clonus and tremor, while a few dozen or hundred passive movements appied to the "vibrated" animals never failed to bring the clonus even several days after the stimulus. When the vibrations were applied to the spine, spasmodic action followed affecting all the muscles in both hind legs. In short, this method of applied vibrations is able to induce in the inferior (somatic) nerve apparatus the phenomena which we are accustomed to attribute exclusively to the brain. The vibrations once applied leave traces which may remain latent for a long time, as in the psychic organ an idea or a sensation may leave a latent trace which persists through a long period and may be revived by some stimulus from the apparatus of psychic association.

38. **Post-Hemiplegic Contracture.**—The contracture appeared in less than twenty-four hours after the hemiplegia. The arm exhibited lax paralysis while the leg was flexed rigidly on the thigh. The autopsy showed the causal lesion to be a circumscribed softening of the internal capsule with degeneration of the pyramidal tract.

39. **Blood Pressure in Traumatic Neuroses.**—Haskovec found that the arterial pressure in seventeen subjects examined was not augmented but occasionally diminished. No regularity was apparent.

40. **Atrophy of Cerebellum and Sclerosis in Patches.**—Thomas adds a third to the two cases he has previously reported of what he calls "olivo-ponto-cerebellar atrophy." The clinical picture is that of the cerebellar syndrome. It has no hereditary or family features and affects elderly persons. In the case described, besides the lesions suggested by the name of the affection, he found others resembling those of sclerosis in patches, and he believes that the two affections coincided. Study of these three cases indicates that the labyrinth, the cerebellum and the cerebral cortex all participate in the maintenance of the equilibrium, and consequently lesions disseminated through these three organs entail disturbances in the equilibrium more pronounced than when the cerebellum alone is affected.

44. **Cytology of Tabes.**—In 13 cases of tabes examined, of four to forty-two years' duration, no regularity could be found in the cytology of the cerebrospinal fluid It is evident that this means of investigation has no value for either prognosis or diagnosis in such cases.

47. **Psychosis with Catatonia Cured by Operation.**—A man of 57 presented an intermittent psychosis with symptoms of paresis and others, resembling those of catatonia, and preceded by a long stage of alteration of character. He had a history of a severe traumatism of the head thirty years before, and the cicatrix was somewhat depressed. This region was explored after cutting an osteoplastic flap of about 50 sq. cm. The dura was not adherent, and after incising it the pia was seen to be much congested and the brain bulged out over the edges of the incision. There were no signs of a focal lesion. The pia was raised where the hyperemia was most pronounced and some of the vessels were crushed in doing this. The region corresponded to the posterior third of the second convolution. The dura was sutured and the flap lightly replaced, but not pushed down quite into its old place. This left a little more space for the brain beneath. During the twenty-one months that have elapsed since, there has been no recurrence of the psychosis or other previous symptoms but the patient has had an occasional attack of epilepsy. He has been able to resume his long abandoned occupation and the rare epileptic attacks are not regarded by his family and friends as detracting much from the success of the intervention.

52. **Epilepsy.**—In Biro's experience at Warsaw with 306 cases of epilepsy he made a special study of the premonitory symptoms of the seizures and the relations between them and to the intensity of the attack. Also the relations between the bladder symptoms and biting of the tongue to other symptoms observed, as well as other details which are set forth in this article of fifty pages in length. Only 14 per cent. were weak minded. The seizures displayed a regularly ascending type in 61 per cent.; an intermittent type in 26 per cent., and a descending type in 13 per cent. In 6 cases he noticed certain post-epileptic symptoms which have previously been regarded as premonitory phenomena. In 1 per cent. the epilepsy was reflex, from adenoid vegetations, and from masturbation in the same proportion. Syphilis was certain in only 1 of the 26 patients over 30, and hereditary lues in none. Alcoholic parents were noted in 14 per cent., and 8 per cent. of all were addicted to the abuse of alcohol. Aura were noticed in 28 per cent. They usually preceded the milder seizures.

54. **Early Diagnosis of Tabes.**—Kollarits tabulates details of 100 cases of tabes studied in regard to their early symptoms. The hypotony frequently confirmed the diagnosis, also the paralysis of the ocular muscles. In one case paralysis of accommodation was the first symptom and the ocular muscles were not affected until later, when a syndrome developed suggesting Basedow's disease, exophthalmus, struma, nervous disturbances and insomnia. As time elapsed, however, the tabes became unmistakable. The patient was a woman of 24 who had acquired syphilis four years previously. In another instance the paralysis of accommodation and lack of pupil reflex, the trigeminal anesthesia and Menière's vertigo were accompanied by the Basedow triad, but the diagnosis of tabes was sustained by the speedy development of lancinating pains and absence of ankle-clonus. In another case the tabes developed at the early age of 21 soon after syphilitic infection, the early symptoms being headache at night, loss of hair and abortion at the seventh month of a macerated fetus, followed four days later by abducens paralysis and in two months with lancinating pains and gradual abolition of reflexes.

59. **Symptomatology of Tabes.**—Sarbo has had 7.4 per cent cases of tabes in 1,200 patients with various nervous affections in his private practice and 2.6 per cent. in 4,000 in hospital and dispensary patients. The proportion of men to women was 83 to 6 in the first class and 87 to 17 in the second. The age ranged from 23 to 73. The longest interval after syphilitic infection before the tabes developed was twenty-seven years and in 10 cases it was only one to five years. In 7 instances both man and wife exhibited tabes. The primary symptom in 67.5 per cent. of 195 cases was lancinating pains, while diplopia was noticed as the first symptom in 3.6 per cent., and gastric symptoms, vertigo or paresthesia were the first in 3.1 per cent. each. Weakness of the feet was the first symptom in 2.7 per cent., and bladder symptoms, gastric crises or impaired vision were each the first in 2.2 per cent. In 1.6 per cent. the girdle sensation first attracted attention; in 1.1 per cent the heart crises or painful lassitude. In .5 per cent. the first symptom noted was dyspnea, deafness, ptosis or the Argyll sign. In the total of 195 cases lancinating pains occurred at some stage of the affection in 93 per cent.; the Romberg in the same proportion and the ankle-clonus was abolished in 91 per cent. Westphal's sign occurred in 89.4 and the Argyll in 88.8 per cent.; analgesia of the peroneus region in 85.5 per cent.; bladder symptoms in 79 per cent.; paresthesia in 72; analgesia in ulnar region in 66 and atrophy or blanching of the optic nerve in 61 per cent.; anisocoria in 46.6 per cent.; bilateral myosis in 21 and mydriasis in 14 per cent.; crises in 13.7 per cent.; paralysis of ocular muscles in 10.5 per cent, and trophic disturbances in 4.5 per cent.

71. **The Hair in Mental Affections.**—Heinicke describes a case in which a broad band of hair became silvery during the attacks of mental excitement but returned soon afterward to its normal color. The patient was a girl of 21, of a well-to-do family, a pronounced case of dementia precox with intervals of apparent health. One or two hours before a psychic attack the white band appeared and the pupils became dilated. At the culmination of the attack the hair was almost silvery. The scalp beneath was also sensitive to pressure. The microscope showed that these hairs contained an abnormal amount of air, and if the air was forced out, the hair regained its normal blonde color. He is inclined to accept the local action of some autotoxin on the brain and scalp as the cause of the phenomena observed.

81 (No. 3.) *Sedatives for the Insane.—H. Pfister.—Die Anwendung von Beruhigungsmitteln bei Geisteskranken.

79. **Feeble-Minded Children in School.**—Laquer expatiates on the extreme importance of recognizing mental deficiency during the very first year or two of school. Appropriate treatment and guidance at this early stage may accomplish wonders while the lack of it confirms the child in its morbid bent. He gives a chart for school inspectors which, if filled out from the child's first entrance into school life and carried along, would soon reveal the lack of normal brightness and the necessity for exclusion from the ordinary school routine in favor of special training.

81. **Sedatives in Mental Affections.**—Pfister has found scopolamin the sovereign sedative, preferable to all others, for the insane. He has never noted any by-effects from the daily subcutaneous injection of 1.5 to 1 mg., even when continued for weeks. It has no cumulative action, and he has never encountered a case of idiosyncrasy. Abrupt suspension causes no disturbance. It is especially valuable for the immediate soothing of very excited patients. Among the hypnotics he considers paraldehyd supreme. He gives 3 to 5 gm. in abundance of water, giving another 3 gm. in exceptionally urgent cases. In three to thirty minutes the patient drops into sleep which lasts for four to eight hours. As much as 15 gm. has been given in some cases daily for weeks without harm.

131. **Latent Diseases.**—The subject of these diseases without obvious symptoms is noted by Bradford, who reviews the principal conditions in which this absence of symptoms may occur. In some instances the onset of acute symptoms indicates an exacerbation of the chronic morbid state and is due to a sudden increase of lesion. More often, however, it is dependent merely on progressive development of the underlying malady or it may be due to complications. The instances of latent diseases which he gives are numerous, including renal sequelæ in diseases of the bladder and pelvic organs, latent cerebral abscess as a complication of ear disease, pericarditis in renal disorders, walking typhoid, pleural effusion, which is often recognized as latent and generally supposed to be associated with pulmonary tuberculosis, latent phthisis, which may exist to a certain extent, peritonitis, which may be present in its most severe and violent forms without any characteristic symptoms, and especially gastric ulcer and malignant disease of the viscera. Many hepatic disorders run a latent course. This is not uncommon in the tropics. Gallstones produce no symptom in the great majority of cases and a patient may suffer from hepatic cirrhosis with no apparent ill effect for a prolonged period. Sometimes the patient appears to suffer from a general peritonitis dependent on perforation, but none such is found, but rather a high degree of atrophic cirrhosis. Brain tumors, nephritis and aneurism of the large cerebral vessels may also exist for a considerable time, and many diseases of the spinal cord and meninges and even the spinal column may fail to be recognized by the patient or the practitioner. Fracture of the spine as a result of sudden movement may be the first unequivocal evidence of the existence of sarcoma or other malignant disease of the bone. Kidney diseases, however, furnish the most striking and frequent examples, not only in such disorders as hydronephrosis and pyelonephritis, but also in cystic disease, and especially in granular kidney and certain forms of Bright's disease. Uremia often, in its most acute form, may be the first intimation of the existence of cystic disease of the kidneys. The great point to be borne in mind is that most of these latent disorders can be detected or, at any rate, suspected by the use of thorough physical examination. It is the symptoms, not the physical signs, that are lacking.

132. **Immunity.**—Grunbaum's third lecture treats of the actions or sera, other than antitoxic and bactericidal, incubation, protective inoculation, relapses and reinfections, predisposition, susceptibility, serum diagnosis, agglutinins, etc., all in accordance with Ehrlich's theory, which he described in his earlier lectures.

133. **Smallpox.**—Thirteen cases of smallpox were experimentally treated with large doses of serum of immunized heifers by Thomson and Brownlee. Three of these were hemorrhagic cases and all died; two of these too early for the treatment to have had any effect. Of the confluent cases, of which there were 4, 2 died; the discrete cases all recovered. The general results of the experiments were rather negative, but the authors believe that further trial is advisable. No action of any kind was observed in the hemorrhagic cases. In two cases where the serum was administered eight to eighteen days before death, no influence seemed to be exercised, although there was ample time for the serum to act. In 6 cases, where the serum was administered from four to seven days before desiccation, the course was modified, but, as 3 of these cases were vaccinated, and in a fourth the vaccination was assumed but doubtful, it is impossible to say that the treatment acted independently of anything else. In one case the serum completely failed to modify the course of a revaccination.

134. **Ethyl Chlorid.**—Having given ethyl chlorid 450 times, McCardie has never had any trouble ascribable to the drug itself. He now gives it with confidence and finds its general action on the circulation and respiration appears to be stimulative. He has not tried it in major operations, because he sees no advantage in it in such cases over ether or chloroform. It is only for short operations that it is specially beneficial. It is safer, he thinks, than ethyl bromid, as the bromid compounds have a more lasting and toxic effect than the chlorid compounds.

138 *The Mode of Entry of Plague Infection into the Human Body. H. E. Deane.
139 An Analysis of One Thousand Consecutive Cataract Extractions. (Continued.) F. P. Maynard.
140 Notes on the Origin of the Presidency General Hospital, Calcutta. (Concluded.) D. M. Moir.

138. **Plague.**—Deane discusses at length how plague infection enters the human body, and combats the notion that it is exclusively through abrasions. He gives a considerable amount of evidence, and concludes that careful examination shows that a very small proportion of the natives display cuts or abrasions, no more than can be found in any large community. When abrasions are found on persons with plague there is an absence of any sign that would render it probable that they were the point of inoculation In a proportionately small proportion of cases skin lesions are observed, which, when appearing early in the course of the disease, seem to point to an entry for the virus, but the evidence is unsatisfactory and the lesions can be more satisfactorily accounted for by supposing them to be manifestations of the general blood infection. Plague, he holds, is contracted by inhalation of the virus. The different symptoms presented in different individuals depend on the individual constitutions, and they may be in part due to the quality and quantity of the virus observed. Infection through the respiratory organs is borne out by the course taken by the disease and its virulence in damp, dark places void of ventilation.

Journal of Tropical Medicine, London.

April 1.

141 *Tropical Hygiene. (To be continued.) W. J. Simpson.

141. **Tropical Hygiene.**—Simpson notices the different conditions in the tropics from those of the temperate and cooler climates, and remarks that one has to adapt himself to the circumstances. For instance, water-sealed closet traps that are considered advisable in cooler climates would be unadvisable in warmer countries, because they are sure to be unsealed by evaporation in summer and pressure through storms in the rainy season. He divides the tropics into the tropical and subtropical regions, including in the latter the region extending to 35 degrees latitude north and south and external to the tropics of Cancer and Capricorn. The irregularity of isotherms is remarked on and also the difference between insular and continental climates. Humidity has a powerful effect, and the distribution of the rains has much to do with the formation of the climate. Rain within the tropical zone is much more decided than in the temperate zone There are no drizzling rains, but the showers, whether short or long, are heavy. This favors, excepting in very porous soils, floods, inundations, and the formation of swamps, which require special attention to drainage for their prevention. The climate impresses itself strongly on the vegetation of the locality; where there is a great variety of plant life, luxuriant growth, the climate is sure to be hot and moist. When the vegetation is less luxuriant, but of the same tropical nature, the climate will be hot, but with plenty of rain, but where the heat is strong and the rain fails, vegetation fails also. Putrefaction and fermentation proceed with much more rapidity in warm climates, especially in hot and humid ones. What is harmful in Europe is doubly so in the tropical regions. As soon as the European enters the tropics he comes under the influence of a new environment, though the illnesses to which he is subject are not, as formerly considered, altogether the fault of the climate but are due largely to unsanitary habits, overfeeding,

intemperance, unsuitable clothing, etc When the food is good, the habitations healthy and the habits what they should be, the death rate is comparatively low. It is difficult to judge the proportion of ill health due to preventable causes, but, putting the individual under favorable hygiene, the mortality which used to be ascribed to the climate can be reduced 10 to 15 times its former rate in the West Indies, and at least five times its former rate in India. The question arises whether, apart from inattention to personal hygiene, insanitary conditions and malaria, residence in the tropics is more unhealthy to Europeans than residence in their own country. It is certain that in the vast majority of cases residence in the tropics for a short time does no harm.

New Patents.

Patents of interest to physicians, March 17 and 24:

722943. Hypodermic syringe case. Thomas A. Chappell, Brownwood, Ga.

722819. Syringe. Wm. M. Decker, Buffalo, N. Y.

722953. Rectal nozzle for syringes. Wm. M. Decker, Buffalo, N. Y.

722954. Vaginal nozzle for syringes. Wm. M. Decker, Buffalo, N. Y.

722976. Bath and fever machine. Frank W. Hall, Ingleside, Ga.

722841. Electrical massage apparatus. Wilbur F. Hedstrom, Los Angeles, Cal.

723042. Valve for syringes, atomizers, etc. Silas Schwerin, Belleville, N. J.

723070. Inhaler. Clarence W. Taylor, Sioux City, Iowa.

723355. Thermometer case. Albert Ashenberger, Elkins, W. Va.

723588. Hypodermic syringe. Fairleigh S. Dickinson, Baynne, N. J.

723456. Apparatus for treating the eye. Henry F. Garey, Balimore.

723268. Inhaler. Karl Greimer. Plauen, Germany.

723291. Strength testing device. John Maitland, Swampscott, Mass.

723735. Massage appliance. Torsten Schillberg, Glasgow, Scotland.

723738. Inhaler. August K. Schulte, Philadelphia, Pa.

723790. Endoscope or other optical instrument. Reinhold H. Wappler, New York City.

723797. Electric thermal therapeutic blanket. Wm. E. Williams, Springfield, Ohio.

Books Received.

Acknowledgment of all books received will be made in this colmn, and this will be deemed by us a full equivalent to those sendng them. A selection from these volumes will be made for review, s dictated by their merits, or in the interests of our readers.

THE PRACTICAL MEDICINE SERIES OF YEAR-BOOKS, Comprising Ten Volumes on the Year's Progress in Medicine and Surgery. ssued Monthly. Under the General Editorial Charge of Gustavus . Head, M.D., Professor of Laryngology and Rhinology, Chicago Post-Graduate Medical School. Volume IV. Gynecology. Edited y Emilius C. Dudley, A.M., M.D., Professor of Gynecology, Northwestern University Medical School, and William Healy, A.B., M.D., nstructor in Gynecology, Northwestern University Medical School. March, 1903. Cloth. Pp. 242. Price, $1.25. Chicago: The Yearook Publishers.

DISEASES OF THE PANCREAS, DISEASES OF THE SUPRARENAL CAPULES, AND DISEASES OF THE LIVER. By Dr. L. Oser, of Vienna; Dr. E. Neusser of Vienna; and Drs. H. Quincke and G. Hoppe-eyler of Kiel. Edited, with Additions, by Frederick A. Packard, M.D., Late Physician to the Pennsylvania and to the Children's Hospitals, Philadelphia; and Reginald H. Fitz, M.D., Hersey Professor of the Theory and Practice of Physic, Harvard University Medical School, Boston. Illustrated. Cloth. Pp. 918. Price, 5.00 net. Philadelphia, New York, London: W. B. Saunders & Co. 903.

THE CARE AND FEEDING OF CHILDREN. A Catechism for the Use f Mothers and Children's Nurses. By L. Emmett Holt, M.D., L.D., Professor of Diseases of Children in the College of Physicians and Surgeons (Columbia University), Third Edition, Revised nd Enlarged. Cloth. Pp. 149. Price, $0.75. New York and London: D. Appleton & Co. 1903.

HEARING ON THE BILL (H. R. 14788) TO ESTABLISH A LABORATORY OR THE STUDY OF THE CRIMINAL, PAUPER AND DEFECTIVE CLASSES, ith a Bibliography. By Arthur MacDonald, Specialist in the nited States Bureau of Education. Had before the Committee n the Judiciary. Paper. Pp. 309. Washington: Government rinting Office. 1902.

DISEASES OF THE STOMACH. By Dr. F. Riegel of Giessen. Edited, with Additions, by Charles G. Stockton, M.D., Professor of Medicine in the University of Buffalo. Illustrated, Including 6 ull-page Plates. Cloth. Pp. 835. Price, $5.00 net. Philadelhia, New York, London: W. B. Saunders & Co., 1903.

THE SURGERY OF THE HEAD. By Bayard Holmes, B.S., M.D., rofessor of Surgery in the University of Illinois. Cloth. Pp. 569. rice, $2.50. New York: D. Appleton & Co. 1903.

SIXTEENTH ANNUAL REPORT OF THE STATE BOARD OF HEALTH OF HE STATE OF OHIO For the Year Ending Oct. 31, 1901. Paper. p. 495. Columbus, Ohio: Fred J. Heer. 1902.

DIE PFLANZENPARASITARE URSACHE DES KREBSES UND DIE KREBSROPHYLAXE. Von Medizinalrat Dr. Robert Behla. Mut 4 Tafeln. aper. Pp. 48. Berlin: Verlag von Richard Schoetz. 1903.

FIFTH ANNUAL REPORT OF STATE HOSPITAL FOR CRIPPLED AND DEFORMED CHILDREN. In Charge of Board of Regents, University of Minnesota. Paper. Pp. 16.

The Public Service.

Army Changes.

Movements of Officers of the Medical Department, U. S. Army, under orders from the Adjutant-General's Office, Washington, D. C., from March 27 to April 4, 1903:

Ashford, Bailey K., captain and asst.-surgeon, U. S. A., is relieved from further temporary duty at San Juan, P. R., and will proceed to Cayey, P. R., for duty.

Beal, Howard W., first lieut. and asst.-surgeon. The resignation of the above has been accepted, to take effect May 31, 1903.

Bacon, Alexander P., contract dental surgeon, will proceed to Vancouver barracks and report to the commanding general, Department of the Columbia, for assignment to temporary duty with the Seventeenth Infantry, and, on the completion thereof, will return to his proper station in the Department of Dakota.

Baker, David, first lieut. and asst.-surgeon, is granted leave of absence for four months from about May 1.

Chamberlain, Weston P., asst.-surgeon, will proceed to Cabana barracks, Havana, Cuba, for duty, to relieve First Lieut. John R. Devereaux.

Collins, George L., first lieut. and asst.-surgeon, will report at Fort Adams for duty on completion of course of instruction at the Army Medical School.

Devereaux, John R., asst.-surgeon, on being relieved from duty at Cabana barracks, Havana, Cuba, will proceed to Fort Columbus for duty, to relieve First Lieut. Eugene H. Hartnett, asst.-surgeon.

Devereux, Thomas, asst.-surgeon, is relieved from attendance at the Army Medical School, to take effect April 7, and will then proceed to San Francisco, Cal., for assignment to duty as surgeon on the transport *Sumner*.

De Loffre, Samuel M., first lieut. and asst.-surgeon, on the completion of the course of instruction at the Army Medical School will proceed to Fort Assinniboine for duty.

Edio, Guy L., surgeon, is relieved from duty at Columbus barracks, to take effect on the arrival of Lieut. Truby at that post, and will then proceed to Monterey, Cal., for duty.

Ford, Clyde S., first lieut. and asst.-surgeon, is relieved from duty at Fort Wadsworth, and will proceed to Fort H. G. Wright for duty, to relieve First Lieut. Howard W. Beal, asst.-surgeon.

Frick, Euclid B., major and surgeon, will proceed to Fort Snelling for duty, to relieve Major Edgar A. Mearns, surgeon.

Gilchrist, Harry L., first lieut. and asst-surgeon, will, on the completion of the course of instruction at the Army Medical School, proceed to Fort Screven and report for duty.

Gosman, George H. R., first lieut. and asst.-surgeon, on the completion of the course of instruction at the Army Medical School, will proceed to Fort Du Chesne for duty.

Gregory, Junius C., first lieut. and asst.-surgeon, on the completion of the course of instruction at the Army Medical School, will report at the U. S. General Hospital, Washington barracks, for temporary duty.

Gapen, Nelson, first lieut. and asst.-surgeon, on the completion of the course of instruction at the Army Medical School, will proceed to San Antonio, Texas, for assignment to duty to accompany the First Squadron, Twelfth Cavalry, to the Philippine Islands. On his arrival at Manila, Lieut. Gapen will report for assignment to duty.

Hartnett, Eugene H., first lieut. and asst.-surgeon, will proceed to Vancouver barracks, for duty in Alaska.

Hansell, Haywood S., first lieut. and asst.-surgeon, on the completion of the course of study at the Army Medical School, will proceed to Fort Monroe for duty.

Harris, Jesse R., first lieut. and asst.-surgeon, on the completion of the course of instruction at the Army Medical School, will proceed to Fort Myer for duty.

Hathaway, Levy M., asst.-surgeon, on the completion of the course of instruction at the Army Medical School, will proceed to Vancouver barracks for assignment to duty in Alaska.

Kirby-Smith, Reynold M., first lieut. and asst.-surgeon, on the completion of the course of instruction at the Army Medical School, will proceed to Fort Barrancas for duty.

Lippitt, William F., major-surgeon, will proceed to San Juan, P. R., for duty, to relieve Major Euclid B. Frick, surgeon.

Mearns, Edgar A., major-surgeon, will proceed to San Francisco, Cal., for transportation to the Philippine Islands, where he will report for assignment to duty.

Lambert, Samuel E., first lieut. and asst.-surgeon, on the completion of the course of instruction at the Army Medical School, will proceed to St. Paul, Minn., for assignment to temporary duty at Fort Keogh, and to accompany the Second Squadron, Thirteenth Cavalry, to the Philippine Islands. On arrival at Manila, Lieut. Lambert will report for assignment to duty.

Newgarden, George J., asst.-surgeon, having completed the duty for which he was ordered to Washington, D. C., will proceed, not later than April 11, to Fort Mason, and turn over the public property for which he is responsible and, on the completion of this duty, will join his proper station at Fort Harrison.

Stockard, James K., contract surgeon, is relieved from duty at Fort Delaware, to take effect on the return to duty at that post of Contract Surgeon William J. Enders, and will then proceed to Fort Du Pont for duty, to relieve First Lieut. Samuel L. Steer.

Steer, Samuel L., first lieut. and asst.-surgeon, will proceed to Hot Springs, Ark., and report at the Army and Navy General Hospital for duty.

Smart, William M., first lieut. and asst.-surgeon, on the completion of the course of instruction at the Army Medical School, will proceed to Fort Leavenworth for duty.

Stewart, William J. S., contract surgeon, on his relief from duty as surgeon on the transport *Logan*, will report for assignment to duty as surgeon on the transport *Dix*, to relieve Contract Surgeon H. Newton Kierulff.

Turnbull, Wilfred, first lieut. and asst.-surgeon, is relieved from duty at Fort Myer, and will proceed to Fort Monroe for duty, to relieve Major William F. Lippitt.

Truby, Willard F., first lieut. and asst.-surgeon, on his arrival in New York City, will proceed to Columbus barracks for temporary duty.

Talbott, Edward M., first lieut. and asst.-surgeon, on the completion of the course of instruction at the Army Medical School, will proceed to Fort Clark for temporary duty, and to accompany the Second Squadron of the Twelfth Cavalry to the Philippine Islands. On his arrival at Manila, Lieut. Talbott will report for assignment to duty.

Scott, George H., first lieut. and asst.-surgeon, on the completion of the course of instruction at the Army Medical School, will proceed to San Antonio, Texas, for assignment to temporary duty at Fort Clark, and to accompany the Third Squadron, Twelfth Cavalry, to the Philippine Islands. On his arrival at Manila, Lieut. Scott will report for assignment to duty.

Pierson, Robert H., first lieut. and asst.-surgeon, on the completion of the course of instruction at the Army Medical School, will report at the U. S. General Hospital, Fort Bayard, for duty, to relieve First Lieut. Horace D. Bloombergh, asst.-surgeon.

Pyles, Will L., first lieut. and asst.-surgeon, on the completion of the course of instruction at the Army Medical School, will report at Washington barracks for temporary duty and to accompany the engineer troops to the Philippine Islands. On his arrival at Manila, Lieut. Pyles will report for assignment to duty.

Williams, Allie W., first lieut. and asst.-surgeon, is relieved from duty at Cayey, P. R., and will proceed to Fort Greble for duty, to relieve First Lieut. Weston P. Chamberlain, asst.-surgeon.

Winter, Francis A., captain and asst.-surgeon, will report on April 1 to Major A. La Garde, surgeon, president of the examining board, at the Army Medical Museum Building, Washington, D. C., for examination for promotion.

The following named assistant surgeons will, on the completion of the course of instruction at the Army Medical School, proceed to San Francisco, Cal., for assignment to duty as surgeons on the transports designated after their respective names, to relieve the contract surgeons now on duty on those transports: First Lieuts. John W. Hamser, *Sheridan;* William T. Davis, *Logan;* Robert L. Carswell, *Kilpatrick;* Cary A. Snoddy, *Sherman;* William A. Powell, *Thomas.*

The following named assistant surgeons will, on the completion of the course of instruction at the Army Medical School, proceed to the posts designated after their respective names for duty: First Lieuts. Robert M. Blanchard, Fort Thomas; James Bourke, Fort Sheridan.

The following named asst.-surgeons will, on the completion of the course of instruction at the Army Medical School, proceed to Plattsburg barracks for temporary duty and to accompany the Twenty-Third Infantry to the Philippine Islands: First Lieuts. John A. Clark, Jacob M. Coffin and James D. Fife. On arrival at Manila Lieuts. Clark, Coffin and Fife will report to the commanding general, Division of the Philippines, for assignment to duty.

The following named assistant-surgeons, on the completion of the course of instruction at the Army Medical School, will proceed to San Antonio, Texas, and report for assignment to duty to accompany the Fourth Infantry to the Philippines, where they will report for assignment to duty: First Lieuts. William H. Moncrief, Charles F. Morse and Clarence H. Conner.

The following named assistant-surgeons, on the completion of the course of instruction at the Army Medical School, will proceed to Vancouver barracks, and report for assignment to duty to accompany the Seventeenth Infantry to the Philippine Islands, where they will report for assignment for duty: First Lieuts. Louis C. Duncan, Philip W. Huntingdon and Noel I. Barron.

The following named assistant-surgeons, on the completion of the course of instruction at the Army Medical School, will proceed to Denver, Colo., for assignment to duty to accompany the Fourteenth Cavalry to the Philippine Islands, where they will report for assignment to duty: First Lieuts. Samuel J. Morris and Harry S. Purnell.

The following named assistant-surgeons, on the completion of the course of instruction at the Army Medical School, will proceed to San Francisco, Cal., and report for transportation to the Philippine Islands, where they will report for assignment to duty: First Lieuts. Leon T. Le Wald, Alexander Murray, Edwin D. Kilbourne and Jay W. Grissinger.

The following named contract surgeons, on their relief from their present duties, will report to the commanding general, Department of California, for assignment to duty, or for orders to proceed to their respective homes for annulment of contract, if their services are not required: H. Newton Kierulff, John P. Kelly, Stephen Wythe, Homer C. Moses and Joseph J. Shafer.

The following named officers will report to Major Louis A. La Garde, surgeon, president of the examining board, at the Army Medical Museum Building, District of Columbia, for examination for promotion: First Lieuts. Weston P. Chamberlain, Edward R. Schreiner, Ira A. Shiner, Douglas F. Duval, Clarence J. Manly, David Baker, Albert E. Truby, Eugene H. Hartnett, Clyde S. Ford, asst.-surgeons.

Roberts, William, first lieut. and asst.-surgeon, is ordered to proceed to Hot Springs, Ark., and report at the Army and Navy General Hospital at that place, for treatment.

Robins, Robert P., contract surgeon, now casually at Fort Porter, from detached service, is assigned to temporary duty at that post until further orders.

Truby, Willard F., first lieut. and asst.-surgeon, is directed to proceed to Fort Ethan Allen for temporary duty, instead of to Columbus barracks, as directed in order of March 27.

Watson, Harry J., contract surgeon, is relieved from duty at the Presidio and assigned to duty as transport surgeon of the Army transport *Sumner.*

Winter, Francis A., captain and asst.-surgeon, in addition to his present duties, will report by letter to Major-General John C. Bates, commanding the Department of the Missouri, for such duty as may be assigned to him in connection with the assembling of troops at St. Louis, Mo.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ended April 11:

Surgeon C. Biddle, detached from the Navy Yard, League Island, Pa., and ordered to the *Minneapolis.*

Surgeon G. T. Smith, detached from the *Puritan* and ordered home to await orders.

Surgeon O. D. Norton, detached from the *Minneapolis* and ordered to the Navy Yard, League Island.

Asst.-Surgeon J. H. Halloway, detached from the Museum of Hygiene and ordered to the *Franklin.*

Asst.-Surgeon E. M. Brown, detached from the Museum of Hygiene and ordered to the Naval Hospital, Norfolk, Va.

Acting Asst.-Surgeon D. P. McCord, appointment revoked, to take effect April 4.

Surgeon E. S. Bogert, ordered to the Naval Academy, Annapolis.

Asst.-Surgeon T. M. Lippitt, retired, detached from the Naval Hospital, New York, and ordered home.

Asst.-Surgeon C. F. Ely, ordered to the Naval Hospital, New York.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended April 9, 1903:

Surgeon R. D. Murray, granted leave of absence for fourteen days from May 1.

Surgeon W. P. McIntosh, to proceed to Lumpkin, Ga., for special temporary duty.

Asst.-Surgeon C. C. Pierce, detailed to represent the service at the meeting of the Florida State Medical Association, to be held at St. Augustine, Fla., April 8 to 10.

Acting Asst.-Surgeon G. H. Altree, granted leave of absence for five days from April 8.

Acting Asst.-Surgeon J. C. Rodman, granted five days' leave of absence from April 8.

Acting Asst.-Surgeon W. S. Walkley, granted leave of absence for two days.

PROMOTION.

E. M. Holt, pharmacist of the third class, promoted to be pharmacist of the second class, effective March 2, 1903.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended April 11, 1903:

SMALLPOX—UNITED STATES.

Alabama: Mobile, March 28-April 4, 2 cases.

California: Fresno, March 1-31, 20 cases, 1 death; Los Angeles, March 21-28, 2 cases; Sacramento, March 21-28, 1 case; San Francisco, March 26-April 2, 5 cases; Stockton, March 1-31, 4 cases.

Colorado: Denver, March 14-28, 49 cases.

Florida: Jacksonville, March 28-April 4, 4 cases.

Illinois: Alton, March 28-April 4, 1 case; Belleville, March 28-April 4, 1 case; Galesburg, March 28-April 4, 2 cases; Kankakee, March 24-31, 1 case.

Indiana: Elwood, March 22-29, 13 cases; Indianapolis, March 28-April 4, 10 cases, 1 death; Kokomo, March 28-April 4, 1 case.

Iowa: Dubuque, March 28-April 4, 1 case.

Kansas: Wichita, March 28-April 4, 2 cases.

Kentucky: Lexington, March 28-April 4, 2 cases.

Louisiana: New Orleans, March 28-April 4, 3 cases, all imported.

Maryland: Baltimore, March 28-April 4, 1 case.

Massachusetts: Boston, March 28-April 4, 2 cases, 1 death; Holyoke, March 21-April 4, 2 cases.

Michigan: Ann Arbor, March 21-28, 1 case; Detroit, March 28-April 4, 15 cases; Grand Rapids, March 28-April 4, 10 cases; Port Huron, March 28-April 4, 2 cases.

Missouri: St. Joseph, March 28-April 4, 1 case; St. Louis, March 29-April 5, 7 cases.

Nebraska: Omaha, March 28-April 4, 7 cases.

New Hampshire: March 28-April 4, Manchester, 3 cases; Nashua, 2 cases.

New Jersey: Hudson County, March 29-April 5, 2 cases.

New York: Buffalo, March 31-April 6, 1 death; New York, March 28-April 4, 1 case.

Ohio: Cincinnati, March 27-April 3, 9 cases; Toledo, March 21-April 4, 6 cases.

Oregon: Portland, April 1, 1 case.

Pennsylvania: March 28-April 4, Erie, 3 cases, 1 death; Johnstown, 1 case; Norristown, 1 case; Pittsburg, 25 cases, 4 deaths.

South Carolina: Charleston, March 28-April 4, 7 cases.

SMALLPOX—INSULAR.

Philippines: Manila, Feb. 13-20, 1 case.

SMALLPOX—FOREIGN.

Brazil: Pernambuco, Feb. 1-28, 9 deaths; Rio de Janeiro, Feb. 27-March 6, 8 deaths.

Colombia: Barranquilla, March 8-15, 2 deaths.

Great Britain: Birmingham, March 14-21, 12 cases, 3 deaths; Bradford, March 1-14, 6 cases; Liverpool, to March 21, 86 cases, 6 deaths; London, March 14-21, 2 cases; Manchester, March 14-21, 8 cases; Nottingham, March 14-21, 3 cases; Walker-on-Tyne, March 7-14, 1 case; Wallsend-on-Tyne, March 7-14, 1 case.

Italy: Palermo, March 7-14, 1 case.

Mexico: City of Mexico, March 15-22, 6 cases, 5 deaths.

Russia: March 7-14, Moscow, 3 cases, 1 death; St. Petersburg, 37 cases, 5 deaths; Warsaw, 4 deaths.

Straits Settlements: Singapore, March 7-14, 4 deaths.

YELLOW FEVER.

Brazil: Rio de Janeiro, Feb. 27-March 6, 27 deaths.

Colombia: Cartagena, March 9-16, 1 death; Panama, March 19-26, 4 cases, 1 death.

Ecuador: Guayaquil, March 7-14, 17 deaths.

Mexico: Vera Cruz, March 21-28, 2 cases.

CHOLERA—INSULAR.

Philippine Islands: Provinces, Feb. 7-14, 570 cases, 270 deaths.

PLAGUE—INSULAR.

Philippine Islands: Manila, Feb. 13-20, 2 deaths.

Original Articles.

AN EXAMINATION INTO THE CLAIMS OF THE RED-LIGHT TREATMENT OF SMALLPOX.

JAY F. SCHAMBERG, A.B., M.D.
Professor of Diseases of the Skin, in the Philadelphia Polyclinic and College for Graduates in Medicine; Assistant Physician to the Municipal Hospital for Contagious and Infectious Diseases.
PHILADELPHIA.

In a small book on "Phototherapy," written by Dr. Niels R. Finsen of Copenhagen, in 1901, he says: "In July, 1893, I proposed a new treatment for smallpox, which consists in placing the patients in rooms from which the chemical rays of the solar spectrum are excluded by interposing red glass or thick red cloth. The result of this method of treatment is that the vesicles, as a rule, do not enter on the stage of suppuration, and that the patients get well with no scars at all, or at most with extremely slight scarring." These claims, if correct, would prove the method to be of inestimable value, not only in preventing the disfigurement occasioned by smallpox, but in saving life, for, as is well known, death in smallpox nearly always results from the variolous septicemia caused by the cutaneous suppuration.

The use of red light in the treatment of smallpox dates back many years, and Finsen's statement, "I proposed a new treatment," is misleading, although I presume unintentionally so, for later he admits that his studies were influenced by the observation of others who had treated smallpox by the exclusion of daylight. The red-light treatment of smallpox was first employed in the fourteenth century by John of Gaddesden, who, though court physician, is said to have been "a very sad knave." Gregory wrote in 1843, "What think you of a prince of royal blood of England (John, the son of Edward the Second) being treated for smallpox by being put into a bed surrounded with red hangings, covered with red blankets and a red counterpane, gargling his throat with mulberry wine and sucking the red juice of pomegranates? Yet this was the boasted prescription of John of Gaddesden, who took no small credit to himself for bringing his royal patient safely through the disease."

Black[1] in 1867 revived the question of the influence of light in smallpox and claimed that the complete exclusion of light even in unvaccinated cases of smallpox effectually prevented the pitting of the face.

A few years later, in 1871, Waters[2] declared that "if daylight is entirely excluded from the patient, there is no doubt the disease is less severe." Barlow[3] stated that a marked contrast resulted in the two sides of a patient's face, one-half of which had been covered with a colored gelatin to exclude the actinic rays of the sun, while the other half was left exposed.

FINSEN'S RED-LIGHT THEORY.

Finsen has further elaborated the red-light treatment of smallpox, although it is said that he has not, or at any rate had not at the time he promulgated the theory, seen a single case of smallpox. He explains the action of red light on the principle enunciated in the following query: "What is more natural than that the chemical rays should exert an injurious influence on a diseased skin, when we see such severe inflammation produced by their influence on the healthy skin?" It has been conclusively established that sunburn results not from exposure to solar heat, but from the action of the chemical rays of sunlight. The use of red panes of glass or red curtains in a room, as urged by Finsen, excludes the chemical rays. It is further stated that in smallpox "the face and the hands, the parts of the body exposed to light, are the seats of the deepest and most confluent scars."

OBJECTIONS TO THE FINSEN THEORY.

There are numerous facts which militate against the correctness of Finsen's view. While prolonged exposure to the direct solar rays, particularly in the hot months of the year, commonly induces inflammatory reaction, yet there is no evidence of such noxious influence by ordinary exposure to diffuse daylight.

Smallpox is essentially a cold weather disease, and the months in which it flourishes most are characterized by cloudy skies and the presence of but little direct sunlight. It is difficult to believe that ordinary exposure in the sick room to diffuse winter daylight could result in any irritative action on the skin. If the theory were correct, summer smallpox should be more severe than the winter type, for the actinic rays of the sun are stronger in the former season. If there is any difference in the character of winter and summer smallpox it is milder in the latter, for during this season the epidemic influence is usually absent.

The predilection of the smallpox eruption for the face and extremities is not because these parts are exposed to light, for it would be difficult to explain on this theory the copious involvement of the feet, which are often attacked as severely as the hands.

There is every reason to believe that the preferential election of the face and extremities is due to the greater vascularity of these parts. That this is true is evidenced by the oft-noted observation that increased vascularity of any portion of the cutaneous surface from the application of an irritant determines the development of lesions in such areas. Time and time again have we observed the use of a mustard plaster, tincture of iodin, kerosene, or the presence of abrasions or sunburn on the skin excite confluence of variolous lesions in the irritated or congested portion of integument. (See Figs. 1 and 2.) But it is here to be noted, and the fact has an important bearing on Finsen's theory, that if irritation of the skin takes place after the appearance of the variolous eruption, it does not increase the number of lesions nor otherwise unfavorably influence the eruption. The augmentation of the lesions only occurs when the skin is congested prior to the appearance of the exanthem. For example, the tincture of iodin applied to the skin before the eruption has appeared, by congesting the skin, attracts lesions to the area painted. We have convinced ourselves that no influence of this kind operates after the eruption is out for we have used iodin painted on the face in hundreds of cases.

---

[1] Lancet, June 29, 1867.
[2] Lancet, Feb. 4, 1871.
[3] Lancet, July 1, 1871.

It appears reasonable, therefore, that the alleged benefit resulting from the exclusion of the actinic or chemical rays of sunlight is not explicable on the grounds maintained by Finsen, for, inasmuch as irritation of the skin after the appearance of the exanthem does not unfavorably influence the eruption, it can not be held that the prevention of sunlight irritation favorably modifies it.

Finsen expresses the view that many remedies which have been claimed to exert a favorable influence on the smallpox eruption have done so through their ability to exclude the solar rays. He says: "The tincture of iodin, which stains the skin yellow, protects it specially from the chemical rays. The solution of nitrate of silver also absorbs these rays and later stains the skin black, by which the rays are excluded."

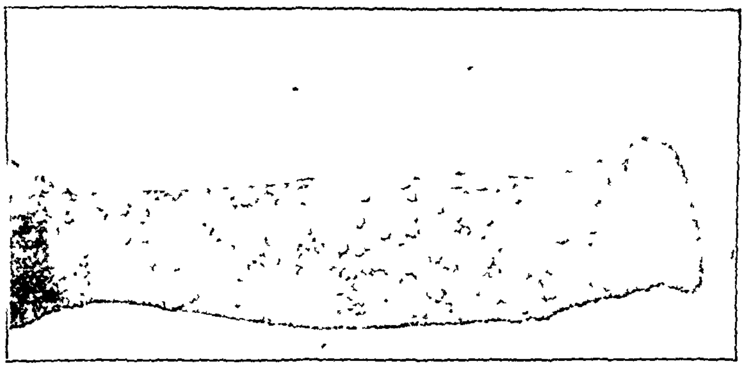

Fig. 1.—Confluence of variolous lesions caused by the application of iodin for a sprain *before* the appearance of the eruption.

If Finsen's theory concerning smallpox and light were correct the negro ought to suffer much less severely from the disease than his white neighbor; the black man has been given by nature the best possible protection against the injurious influence of the actinic rays of the sun. He has a protective layer of pigment in the epidermis which excludes the chemical rays. Does he suffer as severely from smallpox as the Caucasian? Most writers claim that smallpox is more severe in the negro than in the white race; in our experience, however, comparing the unvaccinated of both races, the mortality has been about the same. The absence of any freedom from pitting on the part of the negro strongly challenges the truth of the light theory. Finsen has admitted that "pigmentation constitutes a defense against the effects of the chemical rays," and has proved the truth of this assertion by the following experiment on himself.

"To imitate the color of the negro's skin, I traced in India ink on my forearm a band about two inches wide, and then exposed it for three hours to a very hot sun. I then removed the black color, and the skin under it appeared perfectly white and normal, while that on each side was red." Some hours later the contrast between the protected and the exposed portion was still greater as the latter became swollen and inflamed.

One more theoretical consideration. It does not appear plausible that the exclusion from the skin of the chemical solar rays (those rays which exert a bactericidal *influence*) would be advantageous in dealing with a disease in which there are thousands of small microbe-containing abscesses in the skin.

THE QUESTION OF PITTING IN SMALLPOX.

Pitting is due to destruction of the papillary layer of the true skin by the suppuration of the variolous pocks. The more deeply the skin is attacked the greater will be the scarring. The occurrence or prevention of scarring is less determined by any special method of treatment than by the vaccinal condition of the patient and the severity of the disease. The type of smallpox has been very considerably changed since the introduction of vaccination. Where this agent does not confer complete immunity against variolous infection, it is still quite sure to exercise a more or less marked modifying influence over the disease. Mild smallpox is nearly always characterized by superficially seated lesions. During 1902-03 there were treated at the Municipal Hospital of Philadelphia in the neighborhood of 2,300 cases of smallpox, of whom one-half were not vaccinated, the other half consisting of adults who had not been vaccinated since infancy. In the vast majority of instances the once-vaccinated cases suffered mild attacks and were not scarred. Indeed, at least 60 per cent. of the patients discharged had no indelible scars. The epidemic was mild compared with the severe epidemics of 1871 and 1881, the death rate being about 18 per cent. The most important treatment of smallpox for the prevention of scarring is the prophylactic treatment—vaccination; and yet mild smallpox in unvaccinated persons often runs its course and leaves no scars. This is particularly

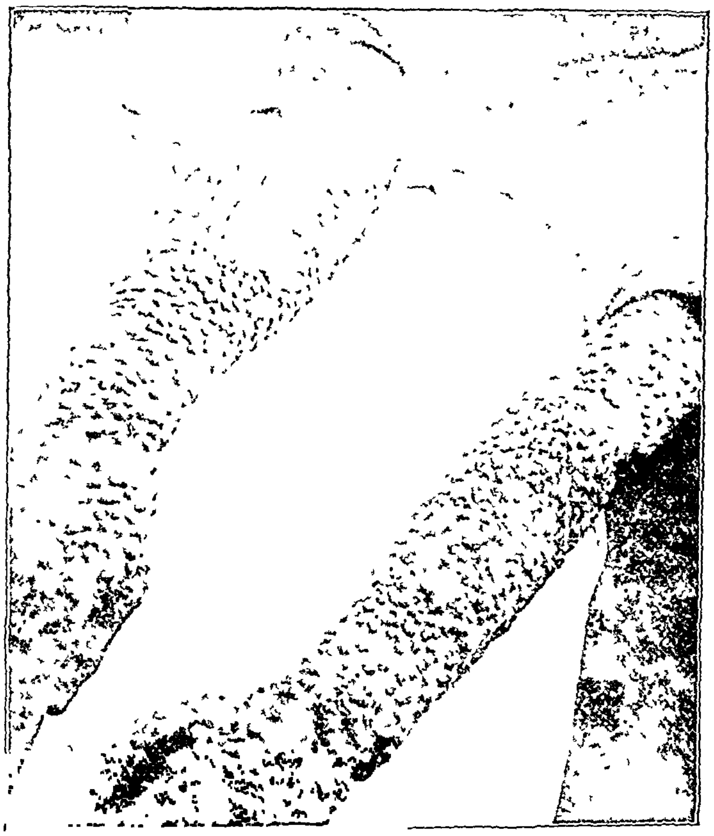

Fig. 2.—Confluence of variolous lesions on the forearms due to sunburn a week or so *before* the patient fell ill with smallpox.

true of children in whom the eruption is, as a rule, more superficially situated.

In determining the value of any remedy in the treatment of smallpox, conclusions should be drawn only from its employment in unvaccinated cases. Furthermore, the prevailing type of the epidemic should not be left out of consideration, for it is a well-known fact that a varying percentage of cases recovers in different epidemics. Certain therapeutic procedures employed during mild epidemics may be accorded an entirely undeserved commendation and value. If during the uniquely mild epidemic of smallpox that has been prevailing throughout the United States during the past few years, some special therapeutic agent had been advised and generally used, there would have appeared no more incontrovertible fact in the history of medicine than that this remedy was an invaluable specific in the treatment of smallpox. And yet the mildness of this widespread epidemic with a mortality rate among the vaccinated and unvaccinated of less than 2 per cent. was not influenced to any appreciable extent by any therapeutic measures. Such observations serve to point out the pitfalls into which the ultra-enthusiastic therapeutist may fall.

PRACTICAL RESULTS OF THE RED-LIGHT TREATMENT OF SMALLPOX.

The treatment of smallpox by the exclusion of the chemical rays of the sun has now been tried by a number of physicians, chiefly in Denmark, Sweden and Norway. Practically all of these men have been favorably impressed with the results.

Drs. Lindholm and Svendsen of Bergen, Norway, treated eight patients, four of whom were unvaccinated children. The latter physician says: "The period of suppuration, the most dangerous and most painful stage of smallpox, did not appear, there was no elevation of temperature and no edema. . . . . The hideous scars were avoided."

Professor Feilberg of Copenhagen employed the treatment in eleven patients. There was no secondary fever and in all the patients the vesicles (?) began to dry up from the ninth to the eleventh day. "In every instance the patient left the hospital with pigmented or hyperemic spots, but without loss of substance of the skin."

Dr. Strangaard of Denmark treated four cases of variola by this method, and stated that he had a "very clear impression that this treatment exercised a favorable influence on the disease."

Dr. Benckert of Gothenberg, Sweden, treated 16 cases of smallpox, 11 of variola vera and 5 of varioloid with red light. Three died, one from puerperal infection, one from hemorrhagic smallpox and one from the fever of suppuration. Dr. Benckert regarded the results in grave cases as surprisingly favorable; "suppuration is usually abolished; scars are extremely rare and the duration of the disease is shorter."

Dr. Mygind of Denmark employed red light in 22 cases of smallpox, of which 12 were variola vera and 10 varioloid. "All left the hospital (save one fatal case admitted late) without loss of substance, but several hyperemic spots."

Dr. Abel of Bergen, Norway, used red light in 23 cases of smallpox, 8 of which were "very severe." All the patients recovered; suppuration did not occur at all, except in one case admitted late. "Even in the patient admitted with full suppuration the favorable effect of the treatment was immediately visible. From the next day the fever diminished and the irritation of the pustules lessened."

As to scars, Dr. Abel thinks that he has not been so successful as other observers. A relatively great number of his patients presented superficial cutaneous changes, especially on the forehead and nose; the scars, however, did not in any way resemble those which are commonly observed. They looked rather as if they had been produced by scratching or some accidental cause.[4]

Dr. Backman treated "62 severe" cases at the fever hospital of Koliikomaki; of this number "three adults died, all of pneumonia, and four children" on the third, fifth and tenth day after admission. "Generally the suppurative period passed off quickly and easily, the vesicles dried up sooner than usual and left no scar at all."

This author has also employed this method of treatment in scarlet fever and measles and has "found the method active, the course of the disease becoming milder and shorter."

Finsen in summing up these cases says that out of a total of 140 to 150 cases of smallpox in one case only (that of Dr. Benckert) was the method inefficacious.

Juhel-Renoy of Paris has not obtained such favorable results as the above quoted physicians. He believes that suppuration and scarring are not prevented but lessened by this procedure.

PERSONAL EXPERIENCE WITH THE RED LIGHT.

During the winter of 1902 Dr. Wm. M. Welch, physician in charge of the Municipal Hospital, and myself fitted up a room for the red-light treatment of smallpox. We regret that we can not recite such results as are quoted above. Although our experience is limited to but two cases, the results were such as to destroy any confidence in this measure that we might have possessed. Our red room was complete in its appointments. The window panes were of a ruby red color, the gas jet at night was surrounded by a red globe, the walls of the room were painted deep red, and a red curtain covered the inner of two doors so as to completely exclude the light of day. Two unvaccinated young men (one 16 years of age and the other 20), who started with profuse eruptions, were placed in this room about the third day of the eruption, before the lesions had become frankly vesicular. The course which the disease pursued in both cases was in no wise different from that seen in patients treated in the regular wards. The pustules filled up and became confluent, the secondary fever was high and protracted, and the patients markedly delirious. One of the young men, who was a private case and had a special nurse day and night with every possible attention, succumbed to the disease. The other recovered, but with most disfiguring scars. Owing to the discouraging results obtained in these two cases, and to the fact that the location of the red-light room made the nursing inconvenient, this method of treatment was abandoned.

It will be urged, and with apparent justice, that an experience with two cases should not be cited to offset the results of treatment in 150 cases. It must be remembered, however, that the red-light method failed absolutely to exercise any modifying influence on the disease in these two cases under appropriate conditions. In the 150 patients, nearly all of whom did well, other factors may be accountable for the good showing. What some physicians regard as severe smallpox, others look on as cases of average or moderate severity. Photograph 3 represents a patient treated at the Municipal Hospital in 1899. Many physicians would regard such a case as one of great severity; yet the eruption was superficially situated, the patient was never dangerously ill, and, indeed, made a good recovery without any permanent pitting.

---

[4] Quoted from Finsen, Phototherapy, p. 32.

Several photographs of patients treated with red light, who recovered with no scarring or only insignificant scars, published in Finsen's book, represent what we in this country would regard as mild and favorable cases, the eruption being on the skin rather than in it.

It must be remembered that Denmark, Sweden and Norway are, with the exception of Germany, the best vaccinated countries of Europe. It is illogical and misleading to definitely attribute favorable results to certain measures employed in the treatment of smallpox in persons once vaccinated. The vast majority of such patients recover without scarring under any treatment and even without any treatment. Again, in the absence of severe epidemics, and there have been no severe epidemics in the past decade, young children with variola (who are, of course, unvaccinated) usually escape without permanent scarring.

The character of the prevailing form of smallpox, whether mild or severe, is a matter of great importance in determining both mortality and disfigurement. During the year ending June 30, 1902, there were in the United States 55,857 cases of smallpox with 1,852 deaths (a mortality rate of 3.31 per cent.), and in the year previous 38,506 cases and 689 deaths (a mortality rate of 1.79 per cent.). What would the verdict have been if red light had been used in these cases?

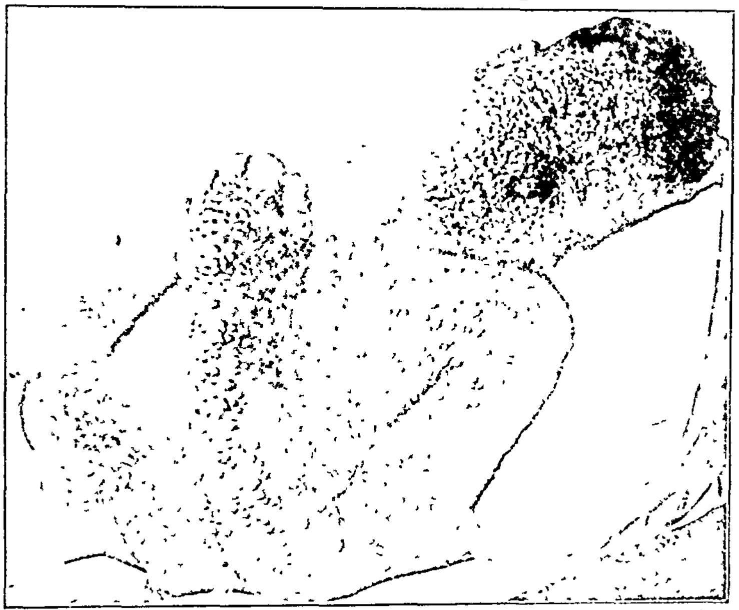

Fig. 3.—Example of a case of smallpox with a semi-confluent but superficial eruption in an unvaccinated mulatto, which was not followed by any permanent scarring.

In the February (1903) number of a popular monthly magazine there appeared several articles on "Niels Finsen and His Healing Rays." Among other unwarranted statements concerning the red-light treatment of smallpox appeared the following: "All the world might now have smallpox without fear of disfigurement."

No one would for a moment endeavor to detract from the hard-earned and well-deserved reputation of Finsen, but in the interests of truth such statements as that just quoted should be challenged.

Automobile Conjunctivitis.—Ophthalmologists report many cases of conjunctivitis caused by rapid riding in automobiles without any protection to the eyes. Davis, in the *Postgraduate*, says it is traumatic, due to friction of the wind and chilling of the eyeball. The treatment is to remove the cause, apply 15 minute cold compresses thrice daily and mild astringent washes by an eye cup twice daily.

THREE ESSENTIAL POINTS IN THE OPERATION FOR CICATRICIAL ECTROPIUM.

F. C. HOTZ, M.D.
Professor of Ophthalmology and Otology in Rush Medical College.
CHICAGO.

Some one once said that blepharoplastic operations look very pretty—on paper—but in reality the results are anything but pleasing and satisfactory. The operations for cicatricial ectropium are not excepted from this criticism. The restored lids often look hideous, and still oftener are again everted after a few weeks or months. But we can overcome these drawbacks if we pay strict attention to the following points:

1. The proper division and fixation of the skin flaps.
2. The selection of the most suitable material for covering the lids.
3. The shortening of the overstretched lid border.

THE PROPER DIVISION AND FIXATION OF THE SKIN FLAPS.

The greatest difficulty we have to contend with in the operations for cicatricial ectropium is the tendency of the shrinking skin flaps to evert the lids again. As all transplanted flaps will undergo more or less shrinkage and as the lid border is least capable of offering any resistance to the traction of the shrinking flap, a re-eversion of some degree is almost inevitable as long as the transplanted flap is attached to the non-resisting lid border on the one side and to the non-yielding skin of the forehead or cheek on the other side, because the lid border is then exposed to the full traction force of the shrinking flap. It is evidently much easier for this flap to pull the lower lid down than to draw the skin of the cheek up, and therefore re-eversion is an especially common occurrence after the operation for ectropium of the lower lid.

It is plain, then, that to prevent the reoccurrence of ectropium we must place the lid border beyond the reach of this traction force. And this can be accomplished if instead of covering the whole wound with one skin flap we make use of two flaps, a small one, which is to cover the lid surface only and which we will call the lid flap, and a large one, which is to be spread over the remaining wound area; and furthermore, if we make provision that the contraction of the larger flap can have no effect on the lid flap.

In ectropium of the upper lid this point is gained if the upper edge of the lid flap (Fig. 1 ba) is firmly attached to the upper border *a* of the tarsus, while its lower edge *b* is united with the free margin. The lid flap is thus anchored above and below to the tarsus and its contraction can not turn the lid over because to do so the traction force must have a fixed point of purchase outside of the lid. The shrinkage of the other skin flap *ac*, which has its point of purchase *c* outside of the lid, however, can not disturb the position of the lid margin, because its pulling force is expended entirely on the upper tarsal border *a*; for, thanks to its firm union with this border, the lid flap can not be stretched or drawn upward by the contraction of the other flap, and as long as the lid flap can not be drawn up the lid border is effectually guarded against re-eversion.

In ectropium of the lower lid, the same principle is adopted for the protection of the lid against the vicious traction of the shrinking skin flap. But we must bear in mind that the tarsus of the lower lid is very small and narrow and that normally the lid skin reaches farther down than the lower border of the tarsus, to a slight furrow a little above the infraorbital margin (Arlt's tarso-malar furrow) where the integument passes from the upright plane of the lid into the sloping surface of the cheek. This normal boundary line between the lower lid and cheek must be re-established by our division and fixation of the skin flaps; and the lid flap *dg,* therefore, must not be united with the lower border of the tarsus, but fastened to the tarso-orbital fascia (at *g*) in a line a little above the infraorbital margin. As the fascia is, as it were, the anatomical continuation of the tarsus, the lid flap adherent to the surface of the tarsus and fastened to the fascia can not evert the lid. And the shrinkage of the large flap *ge* covering the wound of the cheek, is prevented from pulling on the lid margin and causing re-eversion of the lid, because its traction can not reach beyond the firm union of the lid flap with the fascia. So strong is the resistance of this union that you may draw the skin of the cheek down as much as you please and you will not succeed in everting the lid.

THE SELECTION OF THE MOST SUITABLE MATERIAL FOR SKIN FLAPS.

If it is our ambition to obtain the best possible results in ectropium operations—and nothing less ought to satisfy us—we can not be contented with the mere reposition of the lids, but should strive also to restore as much as possible their natural appearance. The lids contribute more to the expression of the eye than the eyeball itself; and the slightest alteration of shape and outline, or the least impediment of motion seriously mars the expression of the face. This is a very important point and should always be taken into account when we choose the material for our flaps. The normal integument of the lids is a thin and delicate skin of such perfect flexibility and adaptability that it allows perfect freedom of motion and accommodates itself readily to the numerous slight changes in contour so characteristic for the various facial expressions. In order, therefore, to gain a perfect cosmetic result we must select as a substitute for the lost lid skin a material which possesses the same qualities; it must be thin, light and adaptable.

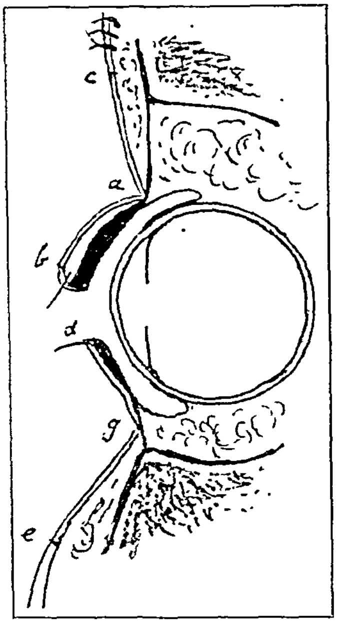

Figure 1.

It goes without saying that the thick skin of the forehead, temples or cheek does not possess these qualities, and therefore flaps from these regions should not be transplanted on the lids. Besides the transplantation inflicts additional wounds on the face, and I hold we should avoid marring the face by unnecessary scars. The use of Wolfe's flaps taken from the arm avoids this latter objection, but they, too, are usually so thick that, like the pedunculated flaps, they make a heavy, clumsy-looking lid. These two kinds of flaps are as well suited for a substitute of lid skin as shoe leather would be for kid gloves.

A good and suitable material for lid flaps which answers all the requirements is the cicatricial skin usually found in the immediate vicinity of extensive ectropium. I have shown in 1896[1] that this skin can be successfully transplanted and makes a perfect lid skin. In ectropium of the lower lid this cicatricial skin can nearly always be utilized for the lid flap. In ectropium of the upper lid it can sometimes be used when the eyebrows are absent. If on account of the eyebrows the cicatricial skin is not available, a Thiersch graft is the only suitable material. It accommodates itself to the surface of the lid, brings out its contours perfectly and does not in the least interfere with the free movements of the lid.

THE SHORTENING OF THE ELONGATED BORDER OF THE LOWER LID.

As the diameter is shorter than the half circle, so in the case of complete ectropium the free lid margin of the lower lid turned from its almost straight line between the canthi into a long downward curve is elongated a good deal; and after being held in this abnormal state for a long while it will not recover its normal length when the lid is replaced. The elongated margin of the lower lid will not closely fit the curvature of the eyeball and will drop away from it, as in senile ectropium. The reposition of the everted lower lid, therefore, can not be perfect and permanent, unless the overstretched lid margin is reduced to its proper length. In several instances I did not do that, because the lid margin appeared to lie in perfect apposition to the globe; but every time I had cause to regret this omission, and had to correct my mistake by a second operation. I therefore regard the shortening of the elongated border of the lower lid a very essential point in the operation for cicatricial ectropium.

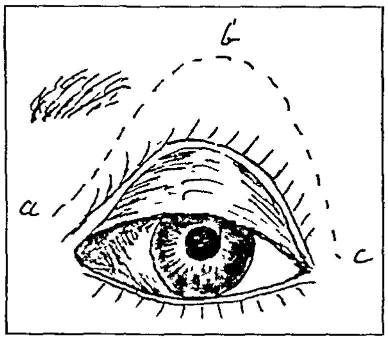

Figure 2.

And now, after having so strongly emphasized the importance of these several points, I wish to indicate briefly the plan of operation based on the views expressed in the foregoing remarks. As the operation is not alike in details for both lids, I believe it is better for a clear understanding to describe the method for each lid separately.

TECHNIC OF THE OPERATION ON THE UPPER LID.

If the eyebrows are partly absent and there is a good expanse of cicatricial skin above the everted lid, we cut from this cicatricial skin the lid flap in the following manner:[2]

---

[1] THE JOURNAL A. M. A., Sept. 19, 1896; and Archives of Ophthalm., vol. xxv, No. 3.

[2] Archives of Ophthalm., vol. xxv.

"From a point (a Fig. 2) about 5 millimeters above the inner canthus an incision is made obliquely upwards into the cicatricial skin and then *continued* in a curve downwards to a point c about 5 millimeters from the external canthus. This incision outlines a large flap *abc* which is carefully dissected up from the underlying scar tissue as far as the lid borders. The lid is then released by dissection from all cicatricial connections until it can be easily turned down into its normal position; and now the edge (Fig. 3 *ac*) of the lid flap is fastened by silk sutures to the upper border of the tarsus."

If, however, on account of the eyebrows the lid flap can not be taken from the cicatricial skin, we make an incision along the lid border and after the reposition of the lid cut from the arm a Thiersch graft of suitable size, which is transported on the razor directly to the lid, spread out over its surface and fastened by fine silk sutures to the upper tarsal border as well as to the wound edge of the free border. These sutures must be inserted with great care to make sure the edges of the flap do not roll in; their application therefore is very tedious work; but the time is well spent, because the graft thus fixed is positively secured against being shifted from its place by any movement of the lid or by any accidental displacement of the dressings.

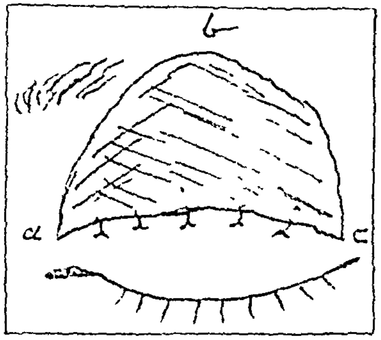

Figure 3.

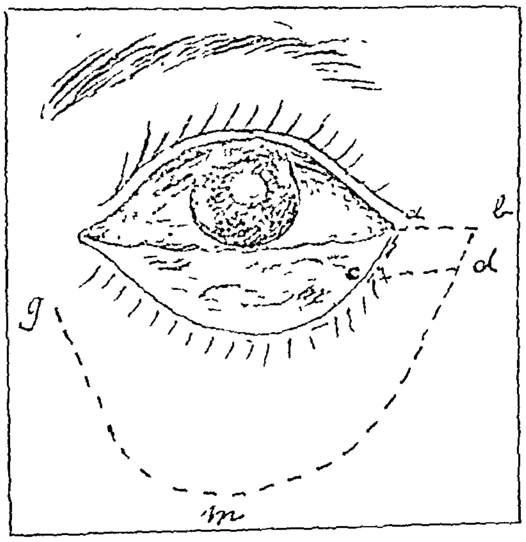

Figure 4.

After the lid flap is fastened (as in Fig. 3) the lid is drawn down as far as possible and held in this position by two ligatures passed through the free border and fixed on the cheek by plaster strips. This is done for the purpose of immobilizing the lid during the healing process and also for enlarging the wound (abc) above the lid to its fullest capacity. Over this wound a Thiersch graft is spread out so that its edges lap over the surrounding skin; no sutures are used.

TECHNIC OF THE OPERATION ON THE LOWER LID.

Here the lid flap can always be procured from the cicatricial skin; but as this skin shrinks considerably as soon as it is dissected up we must take good care to cut the flap of very liberal dimensions. We begin the incision one centimeter below the inner canthus (Fig. 4 *g*), carry it obliquely down into the cheek to a point *m* 2 to 3 centimeters below the center of the everted lid margin; then we continue it *in an oblique direction* upwards and outwards to a point *b* even with and one centimeter from the outer canthus. This large flap *gmb* is then dissected up from the underlying scar tissue and all cicatricial strands and bands are cut until the lid is freed and can be turned up.

The next step is to reduce the overstretched lid margin to its proper length by removing a suitable piece of the lid (except the conjunctiva) near the outer canthus by the following incisions (Fig. 4): from the canthus *a* transversely to *b*; from *a* to *c* along the lid margin, and from *c* to *d* through the flap; the edges *cd* and *ab* are then united by two silk sutures. Now the lid is drawn up as far as possible and held in this position by two silk ligatures passed through the free margin and fastened on the forehead by adhesive plaster or collodion. This done the edge of the lid flap is anchored to the tarso-orbital fascia by silk sutures (Fig. 5). The lid flap should be evenly spread out, so as to be in *perfect* contact with the wound surface; but we must carefully avoid any undue stretching; and should we find that the flap is a trifle short and would be stretched if the sutures are placed very near the infra-orbital margin, it is better to put them through the fascia 1 or 2 millimeters higher up. Finally, the wound surface *gmb* below is covered with a Thiersch graft, the edges of which are made to lap over the surrounding skin. No sutures.

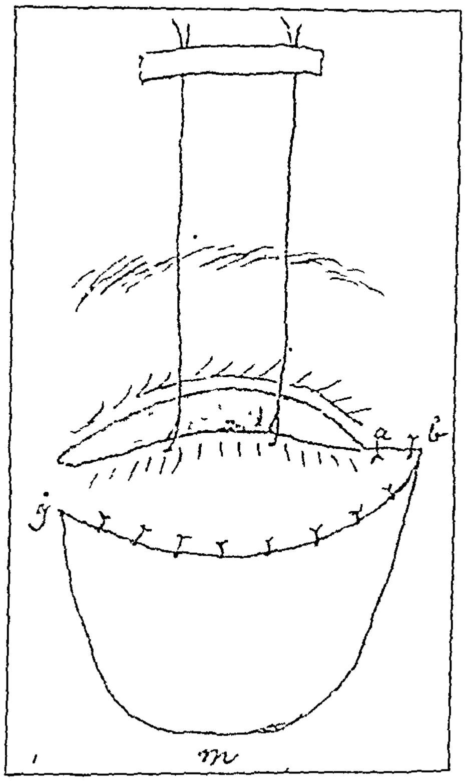

Figure 5.

AFTER TREATMENT.

The after treatment is the same for the upper and lower lid. Strips of gutta percha protective are laid over the flaps, and on these strips a gauze compress wrung out of warm boric acid solution; this is covered by a large square piece of protective to prevent evaporation and over this is put a layer of cotton to maintain uniform warmth. This whole dressing is secured in place by a roller bandage and best left undisturbed for three days. Then it is carefully removed; the flaps are thoroughly cleansed, the overlapping edges of the large flap are trimmed off and a new dressing is put on which is changed every day or two, as circumstances may require. At the end of the first week the ligatures and the sutures of the lid flap may be removed; during the second week some simple ointment (like borated vaseline) is applied daily on the flaps, and after this period no further treatment is required.

THE OBJECTIONS TO PRESCRIBING MEDICINES OF UNKNOWN COMPOSITION.

AUGUSTUS A. ESHNER, M.D.

PHILADELPHIA.

If the proposition contained in the foregoing terms were always presented so clearly and so directly there would be little room for discussion, as I think it will be generally conceded that the fact of the composition of a medicine being unknown would constitute in itself the most serious objection to its prescription by physicians. Nevertheless, I fear that many prescriptions are written daily for preparations concerning whose composition the prescriber is not in possession of such fulness of knowledge as is requisite for the most intelligent and most successful employment of the articles of the materia medica.

The modern manufacturing pharmacist has exhibited marked skill and ingenuity, worthy of a better cause, in concealing ignorance behind the mask of false knowledge. It has become the vogue for this enterprising individual, firm or corporation, to put forth products to which he gives fanciful names, for which he claims elaborately described marvelous effects, and of which he states the composition in accordance with his own views and purposes. He has a predilection for describing his product as a synthetic preparation with a formula comprising C,H,N, and O in startling proportions, and he gives it an almost interminable and unpronounceable chemical name, but is good enough to coin a descriptive and copyrighted substitute. Sometimes it is, at other times it is not, a coal-tar product, according to personal caprice. If the preparation be a mixture, only its constitutents may be named, and sometimes not all of these, the proportions being omitted. In these and devious other ways a pretence of publicity is made, by which the careless and indifferent may be readily if not willingly deceived. Samples are distributed generously to physicians, who read with avidity the accompanying so-called literature skilfully devised by the manufacturer, and it is not long before testimonials indorsing the new preparation are forthcoming, and clinical reports of cases treated with the new preparation appear in certain medical journals. Sometimes the aid of the physician is further invoked by securing him as a stockholder or officer in the manufacturing concern, and his interests may be further looked after in the way of commissions or concessions in return for prescribing the remedy. The preparation is now launched on a career of success and prosperity, which may be of longer or shorter duration in accordance with a variety of conditions. Mayhap when the profession has done all in its power to contribute to this end, direct appeals to the laity, supported by the indorsement of "the medical faculty," are made to the public through the advertising columns of the newspapers and the dead walls and spaces of the city and the country.

The practice of medicine, though art, is based on scientific principles, and it will be successful in proportion to the fulness and precision of the knowledge underlying it. If the identity of a medicine is not known through its composition the prescriber has no assurance that he will always receive the same article, but, on the contrary, there is good reason for believing that he will get something different, in quantity or in quality, at different times. In this way he is liable to do discredit to his art, and injury, positive or negative, to his patient. Additionally, injustice is done the patient in that he is compelled to pay a higher price for medicines of concealed or suppressed composition than he would if these were prescribed in the regular way. The practitioner who permits himself to fall into the habit of prescribing ready-made preparations surrenders thereby originality and independence in his therapeutics, and fails to make progress in his art. The manufacture and the use of secret preparations have also a blighting effect on legitimate pharmacy. Finally, after all has been said on both sides of the question, if there are two sides, there remains the practical argument that the prescription of medicines of unknown composition is unnecessary, as all that can be accomplished with them, barring the potent influence of secrecy, can be brought about as well if not better by means of medicines of known composition.

From the foregoing considerations it must be clear that the prescription of medicines of unknown or concealed composition is unscientific, unprofessional, unfair if not prejudicial to the sick, unprogressive and unstimulating and, most of all, unnecessary.

The remedy for the existing state of affairs is in the hands of the medical profession. The manufacturing pharmacists will not make preparations that they can not sell, and if physicians will not permit the creation of an artificial demand for illegitimate preparations, and will cease to prescribe them, the manufacturers will soon discontinue their production. To this end it is the duty of all medical men having the interests of their profession and their patients at heart to confine themselves to the employment only of such drugs or combinations of drugs whose composition is of public knowledge, and further, is vouched for by some recognized authority, official or otherwise, such as the Pharmacopeia, the Dispensatory and the Formulary; or, in lieu of such indorsement, in the intervals between successive revisions, is given authentic publicity by investigators of acknowledged standing and competency through legitimate and recognized channels, such as the professional journals and independent publications. Above all things, the so-called literature of the manufacturing pharmacist and the reprints of articles from publications of questionable character should be viewed with suspicion.

Habits.—A cheerful habit of mind is like a fountain of youth to the body. Worry kills as surely as does arsenic, but steady, moderate work is a prophylactic against many of the ills to which flesh is heir. The greatest brain workers have generally been long-lived (as witness Gladstone and Bismarck), provided that they did not neglect the laws of hygiene and the natural demands of the body. The physician's irregular hours for eating and sleeping tend to disorder his faculties, depress his vitality and tempt to the use of drugs whose fatal allurements he knows best of [illegible]—*Denver Medical Times.*

A NEW METHOD OF SHORTENING THE ROUND LIGAMENTS INTRAPERITONEALLY FOR RETROVERSION.

HENRY T. BYFORD, M.D.
CHICAGO.

A new era in the treatment of retroversion of the uterus began with the introduction of Alexander's operation. Women had been until then worried with pessaries to hold the uterus in place, and with douches to keep the pessaries clean, yet without being cured.

Abdominal suspension has occupied the attention of the profession considerably in the meantime, but it has not proven a satisfactory remedy, and is being used less than formerly.

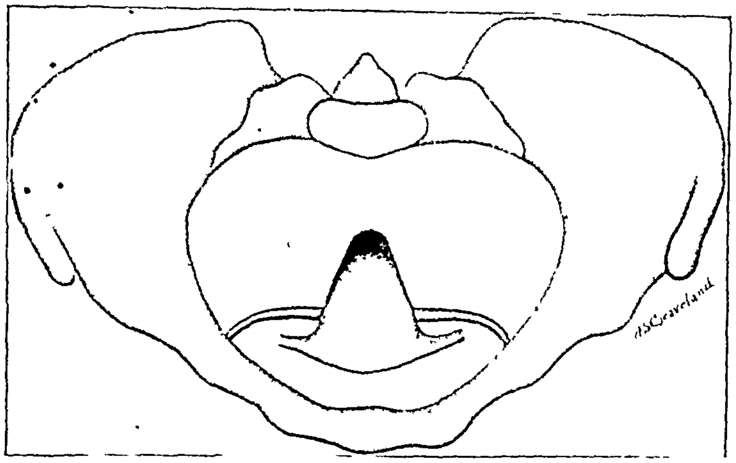

Fig. 1.—Approximately normal round ligaments

Intraperitoneal shortening of the round ligaments has become an acceptable substitute in cases in which it is found necessary or advisable to open the peritoneal cavity, for in such cases the ligaments are accessible without making the additional inguinal incision, and thus with less trauma.

W. Gill Wylie made a backward fold or loop in the ligament and sewed together the edges of the fold, and thus obtained a fair degree of success in holding the uterus in place. A. Palmer Dudley folds the ligament anteriorly and sutures the end of the loop to the anterior surface of the uterus. M. D. Mann folds the ligament somewhat in the shape of a capital letter N and stitches the edges together, thus securing an extensive adhesion of folded ligament. Other methods have been devised, such as A. H. Ferguson's, George H. Noble's, etc., which I have no time to describe.

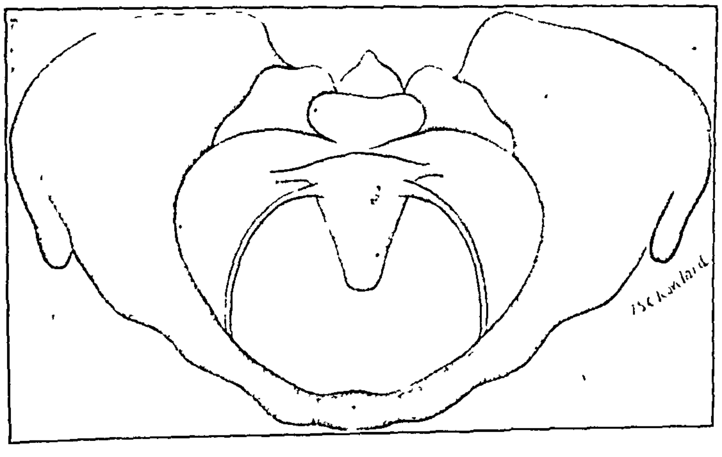

Fig. 2.—Relaxed round ligaments.

I wish, however, at the risk of still farther complicating an already complicated subject, to add another method or, rather, a modification of those already practiced.

It consists in folding the ligaments anteriorly (Figs. 3 and 4), according to Dudley, but in stitching the loop to the abdominal parietes about opposite or behind, and a trifle above, the internal inguinal ring (Figs. 5 and 6).

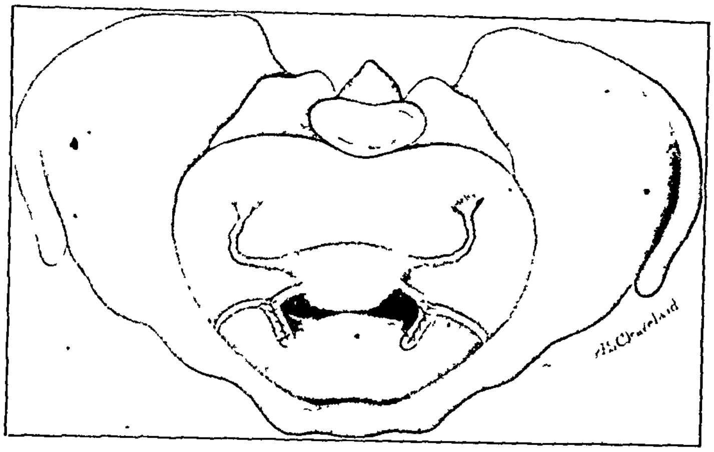

Fig. 3.—Fold taken in ligaments.

The ligament is grasped with hemostatic forceps and pulled out of the abdominal incision until it is drawn as far out of the inguinal ring as possible without doing violence to the tissues. Then a medium-sized catgut suture is passed through the center of the ligament about a quarter of an inch from the uterine end, and the same suture is passed through the ligament about half an inch from the internal inguinal ring. The suture is then drawn tight and tied like an ordinary ligature, except that it, of course, includes only half of the ligament in its grasp. The inner edges of the loop thus formed should now be touched with a chemical irritant, such as Monsel's solution or 1 to 5000 mercuric bichlorid, in order to destroy the endothelium and secure firm adhesions. The irritant is then wiped off and

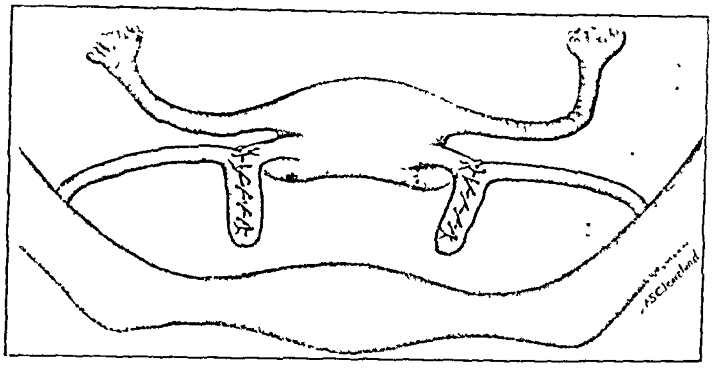

Fig. 4.—Same as Fig. 3.

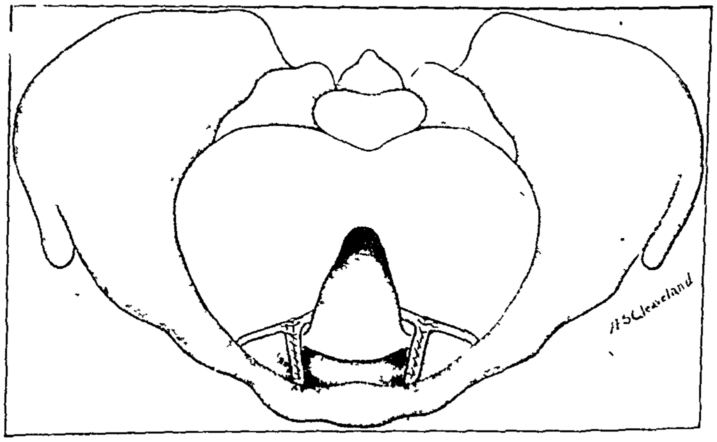

Fig. 5.—Fold of ligament sutured forward.

the edges sewed together by fine catgut that entirely closes in and covers up the irritated peritoneal surfaces.

The end of this fold is then touched with the chemical irritant and stitched forward beside the bladder about opposite and a little above the level of the external inguinal ring. This, of course, will be only a peritoneal attachment and should be rather high, because the peritoneum is held in place here rather loosely.

Thus we practically have two round ligaments on either side, one going from the uterus partly through the first catgut ligature to the attachment behind the external inguinal ring, and the other from the uterus to the ligature and from there to the internal inguinal ring, etc.

The uterine half or quarter inch, or inch, according to the place where we transfix the ligament, is common to both of the newly formed round ligaments.

When there is a tendency to uterine prolapse, I suture the whole side of the fold of the ligament to the peritoneum beside the bladder, or even suture the portions of the round ligaments external to the folds to the parietal peritoneum in front.

When there is decided prolapse. I also stitch the infundibulo-pelvic ligament forward, the fundus uteri itself, and even take folds in the sacro-uterine ligaments.

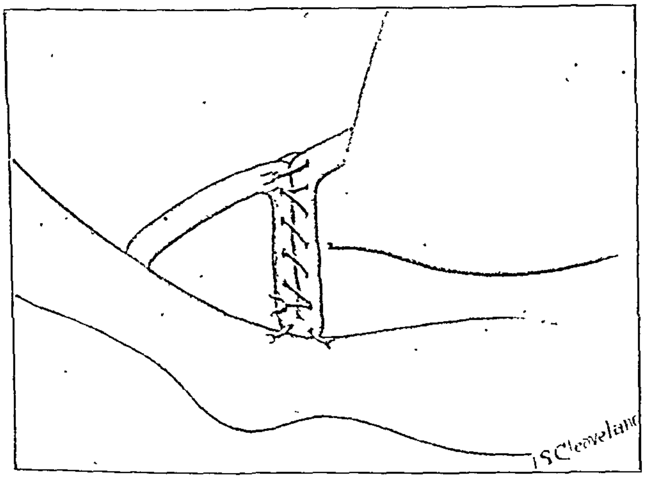

Fig. 6.—Same as Fig 5, showing one ligament.

When there is cystocele, I separate the remains of the urachus with a narrow strip of peritoneum, and after loosely twisting the flap thus obtained and drawing up the bladder, attach the flap into the abdominal wound. A complete description of this method was given in my paper on "Prolapse and Procidentia of the Uterus." read before the Third Pan-American Medical Congress in Havana, February, 1901.

Ferguson's method of shortening the round ligaments is, properly speaking, a prolapse operation. In it he has solved the problem of making the round ligament support a prolapsed uterus, and thus has improved on Nature's methods. Whether his results, which are good, will be permanent or not is for the future to decide. Ferguson makes a new channel for the round ligaments through the abdominal parietes higher up and nearer the median line than Nature has made, and draws the ligaments very taut. The movements of the uterus are more limited, but it is held up more firmly.

THE DIFFERENCE.—The young physician is most likely to err through his anxiety to "do something"; the older one because he has got into a rut.—*Med. Standard.*

THE MEANING AND SIGNIFICANCE OF LEUCOCYTOSIS.*

ROBERT N. WILLSON, M.D.
PHILADELPHIA.

This subject was first considered by the writer a number of years ago, when cases were noticed that failed to fulfill the requirements of the accepted definition of the term leucocytosis. Certain cases, and indeed the great majority, showed under well-known conditions a decided increase in the number of all the forms of leucocytes in the blood.

For a long time it had been believed that the polymorphonuclear forms were, in such cases, always in excess, and in 1897 Cabot accordingly formulated a definition of the term leucocytosis that has until recently served as the standard of teaching throughout the United States, at least. His definition was as follows: "An increase in the number of leucocytes in the peripheral blood over the number normal in the individual case, this increase never involving a diminution in the polymorphonuclear varieties, but generally a marked absolute and relative gain over the number previously present."

The experience of the writer has gradually led him, not only to question the accuracy of the above definition, but to call attention to certain forms of leucocytosis that have been noted by himself and other observers, but of which little has been written or said up to the present time. Actual cases seem to show that in at least two important respects Cabot's definition of 1897 is in error, viz.:

1. Leucocytosis should not necessarily imply an increase in the total number of leucocytes, even in the presence of an active inflammatory influence. The total number of leucocytes may be normal, or below normal in the individual, and a significant leucocytosis still be present, if there is a relatively high percentage of the polymorphonuclear cells. Such an increase implies that the same processes are at work as are suggested by a numerical increase in the total number of cells, and is of even greater import.
2. Notwithstanding the presence of inflammatory causes in the body, exerting influences that are sufficient to produce an absolute increase in the number of leucocytes, the percentage of polymorphonuclear forms may not only not be increased, but even diminished in the individual case, owing to other and more potent specific influences.

In discussing these forms of leucocytosis the terms relative and absolute will be used because they are now generally understood, and also because they have been employed in a similar sense in previous papers by the writer. By relative leucocytosis will be understood all forms of leucocytosis in which the polymorphonuclear forms are in marked excess of the normal percentage (70 to 75 per cent.). By absolute leucocytosis we will imply an increase in the total number of leucocytes in the individual case, irrespective of the percentages of the various forms.

RELATIVE LEUCOCYTOSIS.

This subject has been briefly referred to by the writer in several papers published during the past two years. Its apparent importance has grown with each new case in which it has been noted, until the conclusion seems warranted that not only do many cases occur in which a decided increase in the polymorphonuclear forms is evident in the absence of an increase in the total number of leucocytes, but that such a decided increase in the polymorphonuclear forms under these circumstances suggests either the presence of pus, or some other active inflammatory condition in addition to a grave loss of power in the natural resisting forces of the body.

---

* Read at a meeting of t[illegible] County [illegible] Society, Nov. 26, 1902.

Many clinicians have noted cases in which an absolute leucocytosis has been present and gradually fallen as the energy of the body gave way. Some have even gone so far as to make an occasional observation on such an occurrence. In the same chapter as has already been quoted Cabot says: "In some cases in which the absolute number of leucocytes is not increased we see a relative increase in the adult cells, pointing to the fact that influences are at work similar to those which produce an absolute increase."

Many others, before and since the foregoing was written, and among them Thayer at Johns Hopkins Hospital, have cited occasional cases in which the same theory has been demonstrated as true. Nearly every one has regarded these cases, however, as rare exceptions to the ordinary, and the necessity for being on the watch for a relative leucocytosis as a needless precaution. No one except the writer, up to the time of a recent and unfortunately personal discussion of the value of blood examinations in general, seems to have found the routine examination of the relative percentages of the leucocytes in ordinary conditions either of particular interest or worthy of their attention. At that time he endeavored to show that the blood was not thoroughly examined in any case until a differential count of the leucocytes had been made; and several cases were cited to demonstrate the value of the discovery of a relative leucocytosis of marked proportions. Since the publication of these articles it has been a source of pleasure to learn that in many different directions a renewed interest has been excited in the percentage of the various forms of leucocytes, though with considerable skepticism and doubt as to the value of such study. It would seem, therefore, not out of place at this time to again call the attention of clinicians as well as all blood students, to the value of relative leucocytosis as a clinical sign, and to study its actual significance.

No one will deny that in most cases of inflammation the polymorphonuclear leucocytes show an increase in number out of proportion to the other forms, at the same time with and in the presence of an increase of the absolute number of leucocytes. In such cases, as for example, the ordinary instances of intestinal inflammations, tonsillar infections, appendicitis, pleural and abdominal effusion, pneumonia, etc., the process is expected and regular, and the preponderance of the multinuclear forms becomes the more marked with the intensity of the infection and the increased efforts at resistance on the part of the tissues of the body. In such cases we may say, as we have had occasion to remark before, both the absolute and relative leucocytosis to be of any value must be weighed in close connection with the clinical symptoms, and must never be depended on to form a diagnosis or allowed alone to indicate operative or any other vital measures. The writer has, however, yet to see a case in which either an absolute leucocytosis has been present, followed by a fall to or below the normal number of leucocytes, with a persistence of the high percentage of polymorphonuclear forms; or in which there has been from the beginning a complete absence of absolute leucocytosis, and yet a decided increase in the percentage (85 to 100 per cent.) of polymorphonuclear forms—to repeat, he has yet to see such a case in which there has not been found either a purulent collection, or some grave inflammatory process that threatens the life of the patient.

On the other hand, a considerable number of cases has been previously cited in which the truth of this assertion has been evidenced. The following, including several already mentioned, demonstrate both acute and chronic conditions in which the principle held true.

CASE 1.—*A child, aged 8.* This case presented a moderate absolute and a very high relative leucocytosis. This condition, as noted at the operation, would indicate that the resistance of the body was at a low ebb, and the absolute leucocytosis, therefore, not high. Forty hours previous to the blood examination she was well. Since then she had grown fretful, with pain in the abdomen. Had passed a few large round worms the day before, and vomited one. Her appearance was decidedly septic. Distinct pain and tenderness on pressure centered around the appendiceal region. Rigidity of the abdomen. Blood examination on Jan. 29, 1902, gave H. 74 per cent., r. b. c. 5,824,000, leucocytes 17,200, polymorphonuclear cells 96 per cent. No other pathologic changes in the blood. The operation showed a gangrenous appendix and a large quantity of foul pus in the abdominal cavity.

CASE 2.—A typhoid patient of six weeks' standing. This case illustrates the presence of a marked polymorphonuclear increase in the complete absence of absolute leucocytosis. The patient's general condition improved, and yet the fever chart showed that all was not as it should be; the high percentage of polymorphonuclear cells persisted until the physical signs and the operation demonstrated the presence of pus. In this case the typhoid influence was unfavorable to a leucocytosis, and yet, while it was not overcome sufficiently to allow of the production of an absolute leucocytosis, it was counteracted sufficiently to admit of a polymorphonuclear rise to 96 per cent. The temperature had several times reached normal, and for some days had been bounding up and down in a septic fashion. There had been no chill and no symptom over the body for some time since to account for the temperature. The blood examination, made for Dr. Morris J. Lewis (Jan. 9, 1902), gave H. 95 per cent., R. 4,960,000, L. 7,800; no differential count made. No malarial organisms. No pigmented leucocytes. Jan. 24, 1902, the blood showed H. 70-75 per cent., R. 3,832,000, L. 4,800. Polymorphonuclear cells 92 per cent. No other pathologic change in the blood picture. Condition continued without change and on Jan. 30, 1902, the examination showed H. 78 per cent., R. 4,962,000, L. 9,200, polymorphonuclear cells 92 per cent. On this day a slight bulging was made out in the apex of the vaginal wall. No abdominal tenderness or mass felt then or at any time previous. Operation showed a large ovarian abscess, from the pus of which a pure culture of typhoid bacillus was obtained. The blood examination made the day after operation (Feb. 6, 1902) gave H. 60 per cent., R. 4,320,000 and L. 7,900, the polymorphonuclear cells 72 per cent This last examination was made by Dr. Longcope at the Pennsylvania Hospital, and, of course, after the pus had been evacuated. The case was reported in full by Dr. Lewis at a later date.[1]

Case 3 demonstrated the influence of even a chronic suppurative condition on the percentage of polymorphonuclear cells, and this in the absence of an absolute leucocytosis. The patient was a Swedish girl, with a walnut-sized abscess of the axillary glands. Otherwise well. Blood examination before incision of glands (Feb. 10, 1902) gave H. 94 per cent., R. 5,220,000, L. 7,600, polymorphonuclear cells 94 per cent. No other pathologic blood changes. Blood examination on day following, H. 92 per cent., R. 5,232,000, L. 8,200, polymorphonuclear cells 78 per cent.

CASE 4.—Examined for Dr. F. A. Packard during convalescence from lobar pneumonia of several weeks' standing. Temperature irregular. Pneumonia still unresolved at the base of the lung. Symptoms indicate a pleural effusion, possibly of pus.

---

[1] Amer. Jour. Med. Sc., October, 1902.

Blood examination (Feb. 11, 1902) gave H. 93 per cent., R. 5,264,000, L. 8,400, polymorphonuclear cells 96 per cent. No other pathologic changes. Pleural puncture was made, but no fluid was obtained. From this point on the patient improved steadily and rapidly. This case showed the condition of affairs that one would naturally expect with a mass of leucocytic infiltration in the chest, and throws light only on the novel action of the multinuclear cells in inflammatory processes.

Case 5 resembled in many ways Case 2, in that it occurred in a woman, and also in a typhoid case of weeks' standing. After a protracted course the temperature assumed a septic character, the patient appeared exhausted, an intense cystitis was present, and it appeared possible, if not probable, that a purulent collection was present, either as the result of typhoid infection or secondary to the bladder condition. The physical examination was equally negative with that in Case 2. The blood appeared thin, coagulation was slow; H. 48 per cent, R. 4,160,000, L. 14,200. The polymorphonuclear cells constituted 54 per cent. of the entire number of leucocytes. The Widal test was positive at this time. The case took a sudden turn for the better on the day following the blood examination, and by its subsequent history confirmed the suggestion of the low percentage of polymorphonuclear cells that neither pus nor active inflammatory influences were present in sufficient force to overcome that exerted by the typhoid infection in depressing the number and polymorphonuclear percentage of leucocytes. From that time on the convalescence was steady and complete.

This case was studied not long after the discovery of the purulent collection in Case 2, and with the latter constantly in mind. The presence of 14,000 leucocytes, with a polymorphonuclear percentage of only 54, will be considered subsequently in connection with the second point of our discussion.

This paper was nearly ready for publication when a sad and most striking instance of the occurrence of a high polymorphonuclear percentage with a steadily decreasing absolute leucocytic count, marked the almost certain time of perforation of the bowel in a physician well known to the profession and the public, and an intimate and cherished friend of the writer.

Case 6.—A physician, 39 years of age, with a previous history that was negative except for a slight recurrent bronchitis, and for several undoubted attacks of appendicitis during the past eighteen months.

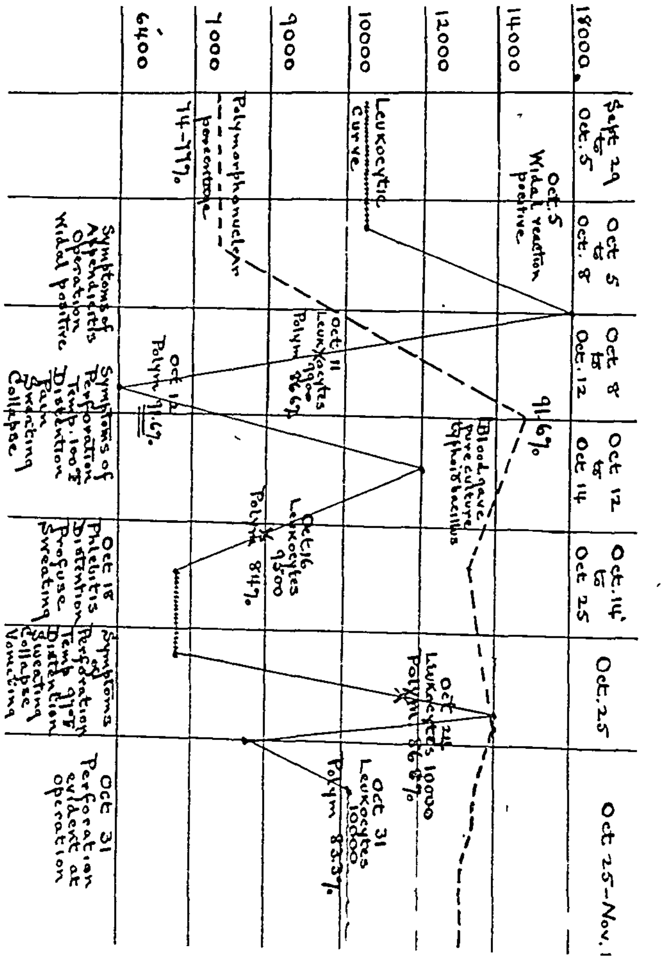
The writer saw him on Oct. 1, 1902, and, realizing that he was facing a serious illness, on the following day, because of close personal associations, transferred him to the care of Dr. Morris J. Lewis. The history of the past two weeks indicated typhoid fever, or a latent, increasing appendicitis, or both. The blood picture when first seen on Oct. 1, 1902, was H. 73 per cent., R. 4,880,000, L. 10,200. No malarial organisms. No pigmentation of leucocytes. No poikilocytosis. No differential count made. Widal test negative. On the following day the symptoms and physical signs suggested appendix trouble. The leucocytes numbered 10,400 and again 10,600. The polymorphonuclear count, however, showed only 74 per cent., and of small lymphocytes 17 per cent. Both of these blood examinations were made by the writer. On Oct. 2, 1902, Dr. Longcope examined the blood. The clinical symptoms still pointed to appendix involvement, rather than typhoid only. The Widal reaction was not yet perfect, though suggestive. On Oct. 5, 1902, doubtful spots were found; the appendix condition, for the first time, appeared secondary. The blood was again examined by the writer, who found the Widal test for the first time positive. The diazo reaction was strongly positive. The leucocytes numbered 9,800, the polymorphonuclear cells 77 per cent., the small lymphocytes were still 17 per cent. On Oct. 7, 1902, the leucocyte count rose to 14,900, and on the following day to 18,400. There was increasing tenderness in the right iliac fossa, and marked rigidity of the right rectus muscle. The appendix was removed. (A pathologic description of the organ will be duly reported by Dr. Lewis. It is sufficient to say that it presented unmistakable evidence of both chronic and acute inflammation.) The Widal test was again positive. On October 9 the leucocytes numbered 14,300; on October 10 14,100; on October 11 the temperature was 104 F., there was a marked chill, and the leucocytes fell to 9,900. The polymorphonuclear count was 86 per cent. No malarial organisms could be found. On October 12 marked signs of weakness; temperature fell to 100 F.; pulse feeble; profuse sweat; extreme abdominal distention and pain; leucocytosis. Polymorphonuclear percentage 91.6 per cent. Small mononuclear forms 4.2 per cent.

October 13.—Blood gave a pure culture of the typhoid bacillus.

October 14.—Wound opened in the lower portion. Marked distention. Profuse sweating. Leucocytes, 10,300.

October 15.—Leucocytes, 7,700.

October 16.—Leucocytes, 9,500. Polymorphonuclear forms 84 per cent. Small mononuclear cells, 10 per cent.



October 18.—Profuse sweating. Both legs slightly tender and swollen. Leucocytes, 7,300.

October 20.—Leucocytes, 8,800. No malarial parasites found.

October 22.—Marked distention and abdominal pain. Leucocytes, 10,000.

October 23.—Much distention, apparently confined to the colon. Leucocytes, 8,300.

October 24.—Marked distention. Leucocytes, 10,000. Polymorphonuclear cells, 86 per cent. Small forms, 8 per cent. During this day and the next severe pain in the left abdomen. Extreme distention. Considerable clear fluid removed from the abdomen. Vomiting. Temperature fell to 97 F. Leucocytes, 14,100.

October 26. Condition much improved. Wound healthy. Serum sweet. Leucocytes, 9,800. Extreme distention. Phlebitis distinct. Leucocytes, 12,250.

October 29.—Pain in left abdomen severe. Leucocyt

October 31.—Pain on pressure to left of umbilicus. Appearance of collapse. Gas and fecal matter escaped from wound on examination. Leucocytes 10,100. Polymorphonuclear cells 83.3 per cent. Small mononuclear forms 13.2 per cent. Operation. Large perforation (size of half dollar) in under portion of transverse colon, and surrounded by a gangrenous area. Region around perforation appeared closed off by exudate and adhesions. Death occurred on the following day.[2]

The last case to which reference will be made is one that came under observation also within the last months, illustrating the same point, though in a different way.

Case 7.—A woman, aged 38, of nervous habit, with a history of longstanding abdominal trouble. During the previous two years she had passed considerable quantities of blood in her urine; a lumbar operation was performed, and a movable kidney sutured in place. Since that time there had been constant and distinct signs of appendicitis until the autumn, when the patient was barely able to keep her feet. She was affected physically, nervously and mentally, and the right side of the abdomen was constantly rigid. With the progression of the case every symptom appeared to point to a collection of pus in the abdomen. The patient was delirious, the temperature that of a septic type, the abdomen rigid, and the history of a longstanding and neglected appendicitis, made the diagnosis of pus probable. The blood was examined just prior to the operation, with a view to confirming, and with no thought of questioning, the presence of pus. The blood picture was: R., 4,010,000; L., 9,400; polymorphonuclear cells, 89 per cent. No poikilocytosis, or other pathologic changes of the red cells. It was agreed before the abdomen was opened that if pus were present under the existing conditions there would probably be present a higher percentage of polymorphonuclear cells, and that the actual percentage (89 per cent.) could be accounted for by a simple inflammatory condition. This was found to be the case, and the operation revealed a long, chronically thickened appendix, containing about one-third of a teaspoonful of serous exudate.

Of course, in the light of cases cited in this paper, conclusions will, and should, be drawn. And yet conclusions should be carefully drawn or not at all. There is no one who will be tempted to say that we know or understand more than a fraction of the significance of relative leucocytosis. And yet, again, it seems certain that there is present in such a series of cases a pointed trend toward a connection between severe inflammatory conditions which appear in a system undermined and threatened with collapse, and a high polymorphonuclear count, especially in the presence of a marked decrease (gradual or sudden) in the absolute leucocyte count.

The most rational explanation of the fall of leucocytes and the persistence of a high polymorphonuclear percentage in cases of this nature appears to the writer to be the following:

In all inflammations and infectious processes the first and prompt tendency is toward phagocytosis, and in the procedure both the total number and the polymorphonuclear percentage of leucocytes increase. It appears that as long as the resistance of the body holds out the total number of leucocytes remains in excess of the normal. When tissue resistance gives way phagocytosis becomes less active, though not entirely done away with, and the total number of leucocytes diminishes. As long as phagocytosis is at all apparent, however, it shows in the increased percentage of polymorphonuclear forms, and at times this is excessive, even when vitality is so low as to be unable to furnish the slightest absolute leucocytosis. In other words, all the forms of leucocytes are diminished owing to the lack of phagocytic energy, which accompanies the loss of vitality in the tissues. Of the leucocytes that still remain there must be a proportional excess of the adult forms as long as any tissue energy remains, since these forms are most actively concerned in the protective processes of the body, and are most in evidence at such a time. It can not be assumed because there has been an excess of polymorphonuclear forms that when the total number falls the polymorphonuclear forms only remain in excess. This is by no means the case in simple acute effusions, in evident pus collections or in pneumonia; on the contrary, with the decrease in the total number of polymorphonuclear percentage also falls, or, as in Case 3, the polymorphonuclear percentage falls with even a rise in the total number of leucocytes. Case 6 seldom showed an absolute leucocytic count of over 10,000, and only once did it rise to 18,000. For the greater part of the time, however, with a constantly low numerical count (4-10000) the polymorphonuclear percentage averaged over 85 per cent., and at the probable time of perforation registered 91.6 per cent. with a total numerical count of 6,400.

Case 7 showed no absolute leucocytosis, a decided though not extreme polymorphonuclear leucocytosis, in the presence of symptoms all of which indicated a purulent condition. Probably the extreme depression of the patient was the cause of the absence of an absolute leucocytosis. Certainly, I think the appendiceal inflammation accounted for the polymorphonuclear leucocytosis, though in the absence of a numerical total increase, and the fact that this polymorphonuclear percentage remained a moderate one (as has not appeared to be the case in the presence of pus) was of decided interest in the light of the actual findings.

At just what point to call the condition a significant polymorphonuclear increase presents a serious question. It seems safe to say that the cases already studied indicate 80 to 85 per cent. of polymorphonuclear cells as a suspiciously high percentage, and in the absence of an absolute leucocytosis a very serious one. Over 90 per cent. would appear to be still more indicative of active and grave inflammatory processes, and usually suggestive of purulent or other leucocytic exudates or effusions. Pneumonic consolidations give this picture, as may also acute and chronic pus collections, and nearly all septic intoxications. If in any of these conditions the absolute leucocytosis disappears, and the polymorphonuclear percentage continues high, we have a warning of overtaxed powers of resistance. As all powers finally give way even the polymorphonuclear percentage must fall, as it is the last sign of a worn-out energy. It is not safe to form iron-bound rules for new principles; but if any new principle seems to be well grounded on fact it is the one that urges scrupulous attention to a patient whose leucocytes show a high polymorphonuclear count in the absence of an absolute leucocytosis.

ABSOLUTE LEUCOCYTOSIS.

Far less need be said at the present time in regard to the occurrence of an increase in the total number of leucocytes in the blood under inflammatory and similar conditions. There is still in existence, as there always will be, a small body of men who persist in striking at the phantom of a leucocytosis that will diagnose a case or decide difficult operative questions. Needless to say they will wear themselves out in the effort and with no injury to the ghost that never assumed material form. The great mass of clinicians (and this term includes distinguished clinicians as well as a large class of so-called country doctors that are not a whit behind the city men in energy and up-to-date methods of medical diagnosis) is learning to look on the occurrence of an absolute leucocytosis as only a clinical symptom, though sometimes a very significant one. It may occur in slight degree in absolutely healthy persons; it may also point to a fatal condition. In every instance the particular individual and the particular leucocytosis must be considered together in order to obtain any value from the study and in order to avoid error.

---

[2] These notes are inserted owing to the courtesy of Dr. Morris J. Lewis, who will report the full clinical history elsewhere.

In many cases nothing new will be learned from the examination of the leucocytes; in many others invaluable information will be derived. Moreover, it can not be denied that in certain conditions even a pus collection may be so nearly walled off from the general circulation as to have no serious effect on the processes required for a seemingly healthy existence. Such an instance is seen in occasional large abscesses of the liver, especially the tropical form, which are known to have existed beyond shadow of doubt within active persons for years before evacuation. Sometimes these fail to cause an absolute leucocytosis, even though the resisting powers of the patient are good; and the explanation of its absence must lie in the fact that a membrane of such density is formed as to protect the circulation from the influence of the purulent process, and must in like manner prevent the very process necessary to the production of a leucocytosis. Just as fever, pain and swelling may all be absent in the presence of a pus collection surrounded by a dense fibrous membrane, so the absolute leucocytosis seems occasionally to fail, and for the same reasons. The writer has as yet, however, never seen a case of so-called walled-off abscess in any portion of the body that failed to present a relative leucocytosis of the polymorphonuclear cells.

It seems hardly necessary to state that the leucocytes vary normally from 5,000 to 10,000 in a single individual, and that digestion and exercise are two of the most common causes of such variation. Any text-book on the blood will advise the reader that a leucocytosis, to be significant, must be of decided proportions, and certainly an increase over the number normal in a given person. Most text-books, however, fail to state that the presence of a leucocytosis is one clinical sign, and that there is no clinical sign known to-day whose value is not to be estimated as part only of a complex picture. The fact is also usually overlooked that one examination of the leucocytes is not only unsatisfactory, but often misleading; and that frequent and even constant examinations must be made in order to obtain the full and certain value of any study of the blood. No number of leucocytes can be fixed at which we can say that pus or any other inflammatory or infectious condition is present. In one subject 20,000, in another 50,000, and in another double that number, of leucocytes will be found suggesting identical conditions, and yet each of these figures is suggestive of a certain order of process that will be still more strongly indicated by the complete clinical picture. There has never been a more untrue accusation than that the students of leucocytosis are endeavoring to decide on operative measures and make diagnoses that will rest solely on the blood picture. Such accusations are always made by men who have heard and believed the enthusiastic beginner, or who hear half a statement and lose the gist of the argument because they have not had time or interest to listen carefully or well. Such men make serious mistakes, as the result of a misuse of a valuable clinical sign, and lay the blame for a result for which they themselves are solely responsible at the door of an innocent and valuable measure.

Perhaps one of the most pertinent suggestions given by an increase in the total number of leucocytes is obtained when constant examinations show either a persistently high count, accompanied by symptoms and physical signs that point to a localized process, or a gradually but steadily increasing count (total) under similar conditions. A gradually falling leucocytosis usually indicates a bettering of the general physical condition. We have already laid sufficient stress on the study of the polymorphonuclear percentage to fear that this last assertion will be misinterpreted. Occasionally every physical sign and symptom will abate and improve, and the total number of leucocytes fall to or below normal, though the actual condition is one of grave seriousness. In such cases the relative leucocytosis may be relied on to warn of impending danger; at this point all clinical symptoms and signs fail. Procedures must, in the light of our present knowledge, be undertaken that may not seem clearly warranted, and with the full knowledge that the interior of the body presents riddles that can not always be deliberately solved. Any and every leucocytosis should be looked on with grave suspicion, but with the full knowledge that it is only one clinical sign, and that clinical signs are only signs after all. The prevailing wind may cause them to point in the wrong direction. When this is fully realized the so-called dangers of blood study will have been lost sight of, and certain reluctant semi-students will fall into the line of those who use to full advantage every form of leucocytosis that may be found present, after a number of thorough examinations of the blood has been made. They will then no longer insist either that the breath sounds are always absent over a pleural effusion, or that a leucocytosis, when properly studied, is misleading. The experience of men who are to be trusted has too often proven both of these beliefs to be without foundation.

The final and all-important question is: "Of what clinical value is a leucocytosis to the practitioner?" The experience of the writer at the bedside and in the laboratory leads him to answer as follows. As long as the clinician considers first the physical signs, then the temperature chart and history of the case, and lastly the report of the laboratory examinations of all obtainable excretions and secretions, and finally all three in their proper relation to one another, just so long will he find the presence of a leucocytosis, whether absolute, relative, or both, of inestimable aid. Its presence or absence should never, let it be once again repeated, alone decide in favor of one diagnosis or form of treatment or another; or persuade the surgeon to operate unless other indications of convincing nature are present. But in their presence such evidence as a marked absolute or polymorphonuclear leucocytosis must assuredly bear great weight; and when followed day by day—as it should be in a serious case—a leucocytosis may point to the correct solution of a grave problem. Who knows but that what we have learned from the behavior of the leucocytes in cases such as have been presented may save to us precious lives such as that so recently lost to the medical profession and the world at large. Experience and desire were at a loss to ascertain either the state of affairs within the abdomen or the proper course to pursue; another hint in such a case is beyond price. In a sudden rise, or a steady gradual increase from hour to hour, or from day to day, we have a sign board that means danger, and points to a careful study of physical signs. A leucocytosis never can indicate pus, or any other inflammatory condition, and should never be allowed to influence treatment in the absence of other equally convincing evidence.

In certain conditions a leucocytosis indicates the retention of considerable resisting power on the part of the patient, as in pneumonia; and in like manner in the presence of pus, the physician would fear to see the number of leucocytes fall while the purulent collection remained in the body. It is a different matter when the total number of leucocytes is low, and the polymorphonuclear percentage is very high. It may then be inferred that a grave condition is present, and it is fair to assume that the polymorphonuclear increase is the indicator of all that is left of resisting power on the part of the body. Let this loss of tissue energy decrease still further and if the principle hold true even the polymorphonuclear increase must fall with the complete collapse of phagocytic action. We have still much to learn from the study of actual cases, but we have progressed far enough to lay hold of certain indications that will be valuable when other signs have failed. It is warrantable to state that no case has as yet been observed in which normal processes have been accompanied by such a blood picture.

ABSOLUTE LEUCOCYTOSIS IN THE ABSENCE OF POLYMORPHONUCLEAR INCREASE.

Case 6, as already noted, furnishes at least one instance of the occurrence of a moderate leucocytosis (absolute) in the absence of an increase in the number of multinuclear cells. (See footnote at end of article.) Just what significance to ascribe to this is not easily determined. There were present a typhoid infection that would tend to diminish the absolute number of leucocytes (which it failed to completely do), and the polymorphonuclear percentage, and also a cystitis that would have the opposite influence. The result seems to have been a compromise. Probably the typhoid infection was by far the most potent influence, and certainly it was the one that at that time dominated the system. The cystitis was also, no doubt, of typhoid origin; and yet the pus formation must have been so local in its influence, and so completely drained through the ready outlet through the urethra, that the suppuration had little or no influence on the general economy in comparison with the typhoid poison. Occasional cases of typhoid fever, and, in fact, certain normal persons, present an average leucocytic count of several thousand above the customary figure (5,000 to 10,000), and 14,000 in this case may not have been a leucocytosis. It appears more likely, however, that it did represent the slight influence of the local suppuration on the blood and tissues, held in check by the typhoid infection. Other and similar cases have been noted in which the absolute leucocytosis was even of a less degree and therefore even more questionable.

CONCLUSIONS.

The following conclusions seem warranted:

1. The term leucocytosis must include every increase in the absolute number of the leucocytes of the blood examined, as well as every increase in the percentage count of the various leucocytic forms.

2. A leucocytosis, of whatever nature, must always be regarded as a clinical sign of importance, but never of such weight as to influence against equally convincing physical signs.

3. A high percentage of the polymorphonuclear forms in the absence of an absolute leucocytosis indicates the presence either of pus or of some grave inflammatory process, together with a low vitality of the patient.

4. Specific factors may rarely exert such an unusual influence as to interfere with the customary reaction of the polymorphonuclear cells. At least one instance has been noted in which the total number of leucocytes was increased at the same time with a marked reduction in the number of the polymorphonuclear forms. This condition is, probably, seldom encountered.[*]

5. Single counts of the leucocytes, or single estimations of the leucocytic percentages are often misleading; while a persistent series of observations will seldom fail to aid in the diagnosis and treatment of the condition.

6. A gradual, but steady, rise in the total count of leucocytes above the customary number usually indicates the presence of an active and augmenting inflammatory influence. When this increase reaches large proportions it may be looked on as an indication of the presence of an active leucocytic process (seroses or purulent effusion, localized pus collection, pneumonic exudate, etc.), provided the clinical picture also bears out the suggestion.

IS THE CONSUMPTIVE CHEST FLAT?

WOODS HUTCHINSON, A.M., M.D.
Late Professor of Comparative Pathology, University of Buffalo.
PORTLAND, ORE.

Some years ago, in the course of a study of the disease-liabilities of the human as compared with the animal chest, I was led to take some measurements of the diameters of the human chest at various ages and in certain diseases. The results of these were somewhat unexpected, and led to further researches, of which a preliminary report was read before the Philadelphia meeting of the Association in 1897, and published in THE JOURNAL of the American Medical Association, Sept. 11 of that year.

Since that time I have been gradually accumulating further data, though unfortunately delayed by a period of impaired health, and as these are now sufficient in number to give a reasonable probability of correctness to deductions drawn from them, I have ventured to again report progress through the columns of THE JOURNAL. A short résumé of the position taken in my former paper will be necessary to clearness.

My views may be briefly summed up in the statement that the tuberculous chest instead of being flat is really round; that the antero-posterior (sagittal) diameter, instead of being diminished relatively to the transverse, is, on the contrary, increased, so that the term "flat-chested," as applied to the consumptive, is really a misnomer.

So far as I have been able to discover, no text-book—with the exception of the last edition of Cabot, which mentions my findings—or other authority on physical diagnosis supports this view; on the contrary, most of them directly controvert it. Manual after manual of physical diagnosis repeats, parrot fashion, the time-honored statement that the typical tuberculous chest is flat, in support of which is shown one ancient drawing of what I am strongly tempted to regard as a purely ideal chest-outline, usually copied from Gee, and by him derived from heaven knows what remoteness of antiquity. It is therefore with a full realization of the unorthodox and perhaps insufficiently tested character of my position that I shall proceed very briefly to outline my reasons for the belief that is within me.

---

[*] Since the preparation of this paper the writer has had the privilege of studying a case of appendiceal abscess, yielding a pure culture of the colon bacillus, in which later an abscess formed posterior to the bladder, and still later another posterior to or within the liver, the pus from both of which also gave a pure culture of the same organism. The total count of the leucocytes varied from 20,000 to 46,000, and at no time was the polymorphonuclear percentage above 80, usually ranging from 70 to 75 per cent. The influence of the colon bacillus on leucocytosis will be discussed in a later full report of this case.

As all are aware, the human chest is, with one or two exceptions (the bats and the whales), almost unique in the animal kingdom, in that its transverse diameter is the longer, and this, of course, is obviously associated with the locomotive necessities of the anterior limbs in the quadrupedal and the erect positions respectively. The animal or quadrupedal chest having to be carried between the parallel-moving anterior limbs, naturally disposes its air space in the shape of a box, having as little width in its anterior part as is consonant with sufficient heart room and general vigor. Of this the familiar "deep" chests of the hound and of the race horse are illustrations which will occur at once. It may be remarked in passing that in every order of vertebrates it is the exigencies of locomotion which seem to determine the shape of the chest. Even before lungs are present it is "deep" in the earlier forms, the fishes, for obvious "yacht-shape" reasons; rounded in most amphibians and reptiles which crawl flat-bellied, with legs (if present) wide apart; rounded in birds with their wide-apart wing attachments, although crested with a great keel which gives it an opposite appearance; "deep" again in all quadrupeds with their parallel-moving anterior limbs, but flattening out in the fliers, like the bats, the pure swimmers, like the whales, and our own biped-climbing, upper families, the apes, and man.

The impression under which I began my study of the disease-liabilities of the two forms of chest was that the human chest had become more subject to disease from over-specialization, so to speak, and that the consumptive chest would be found to be, if I may use the term, the super-human chest form, having departed farthest from the normal type and vigor. To my astonishment, however, I found that my first six or eight measurements made on consumptive chests, showed an actually greater antero-posterior diameter relatively to the transverse one than the normal chest. I concluded that I must have been mistaken, and returned to the attack on fresh cases. But to my surprise the first result was absolutely corroborated by almost every successive case, until finally, when I had collected about forty measurements of tuberculous chests, I found that the average index of these was nearly ten grades higher than that of the normal.

First of all, however, I found myself compelled to establish or determine what was the normal chest index —and, indeed, to invent the index for myself. By "index" I simply mean that same statement of relation between diameters which has proved so exceedingly useful in craniology, applied to the chest. Taking the transverse diameter as 100, I express the antero-posterior diameter in percentages of this, just as is done between the antero-posterior and transverse diameters of the cranium. This I found to be, from measurements of about 50 normal chests of students, and soldiers in the garrison at Buffalo, through the kindness of my friend, Major Appel, then surgeon-in-charge, to be about 70; in other words, the antero-posterior diameter, or "depth," of the normal chest is about 70 per cent. of its width. After I had secured these measurements for myself, my search for other measurements giving a chest index was finally rewarded by the discovery of a large number of measurements taken by Dr. Seaver on the students in the Yale gymnasium, these covering 2,300 individuals, and giving almost precisely the same index as I had already elicited, namely, 70. This, then, I think, may be fairly taken as the average index of the normal chest, although, of course, I wish to be distinctly understood that there are very considerable variations, some of the measurements having gone as low as 62 or 63, and a few having gone even as high as the tubercular level of 80, or above. The average index of the 40 tuberculous cases, on the other hand, was 79½, making them nearly 14 per cent. (10 degrees) deeper than the normal chests.

This result at once brought into suggestive prominence the well-known fact that this round chest was the normal state of affairs in infantile and child life, and I proceeded to make a number of measurements of embryos from the fourth month up, of infants, of children, and of boys and girls up to the ages of 17 or 18, with the result of finding that the axes or diameters of the chest at birth were nearly equal, giving it an index of 101; in the embryo the index runs as high as from 105 to 115; in children under two years, the index had fallen to about 94; in children from 3 to 7 years the index averaged 85; while in boys of from 14 to 18 years of age it had flattened down to a little above 80.[1] The conclusion was obvious, that the type of chest most common in tuberculous cases was a persistent immature chest, in other words, was a chest which had practically retained the form normal at about the age of from 15 to 18 years.

I could still hardly bring myself to believe that such was the case, until I began to examine critically the actual chest shape in apparently flat-chested boys and children, when I quickly discovered the optical delusion, which has given rise to our prevailing conceptions as to the flatness of the immature and of the tubercular chest.

Briefly stated, flatness of a chest is merely an index of the position of the shoulders. Your flat-chested individual is almost invariably round shouldered, and if you will simply take the trouble to seat your flat-chested child or consumptive patient on a low stool, put your knee in the middle of his back, a hand on each shoulder, and pull the shoulders back into something like their normal, dorsal position, you will at once see, on looking down the front of his chest, that the actual shape of the rib-cage is rounded and barrel-like. Indeed, it is this very shape which has given rise to the abnormal position of the shoulders.

In the normal chest the posterior surface of the chest wall is sufficiently flat to allow the inner surface of the scapulæ to rest comfortably on it, and the shoulders fall back easily and remain naturally in the so-called erect, or military, position. In the rounded chest of the child or the consumptive, on the other hand, the scapulæ, having no flat surface on which to rest securely, their lower angles projecting out "like wings," as some poet-anatomist has said (alar), from the sharply rounding chest wall, roll forward in the direction of least resistance, pulled also by the great pectoral muscle-sheets, and come to rest, instead of, so to speak, at the outer and upper corners of the chest, almost on its anterior wall. The so-called "muscle-bound" plowman or bench workman has almost the same sort of shoulder position. In fact, almost incredible as it may seem, we have been misled by analogies drawn from the animal kingdom, and instead of the "deep," human chest, that is, the chest with the long antero-posterior diameter, being the type of vigor, it is just the reverse. and the *healthy, vigorous*

---

[1] For [illegible] measur[illegible] my "Studies in [illegible]

human chest is the broad, flat, well-expanded, low-indexed type.

A moment's consideration of the mechanism of respiration in the two cases will, I think, show the truth of this, at first sight, almost absurd conclusion. Both of them are, for mechanical purposes, bellows. In the quadruped, on account of the position, and necessity for parallel movement, of the anterior limbs, the bellows must be turned, so to speak, on its side, and the largest part of the respiratory movement must take place behind the shoulder girdle, of which the heaving flanks of the grey-hound or the rapidly-galloped horse are striking illustrations.

In man, on the contrary, after the erect position has been assumed and the shoulder masses have rotated outward and backward, in order to give freer play to the hand and arm for the use of the tool and weapon, the scapulæ come to lie at first on the outer and finally on the posterior or dorsal aspects of the chest. This, with the lateral pressure of the arms and elbows, leaves the anterior surface of the chest freest, and the movable flap of the lung bellows becomes turned in that direction. So that the antero-posterior range, which is almost absent in the quadruped, becomes equal to, if not slightly in excess of, the lateral flap-swing. At the same time, of course, the diaphragmatic respiration has become relatively less than in the quadruped, loaded, as that great muscle sheet has now become, with a share of the weight of the liver, in the erect position.

Thus the relative value of the different factors in respiration has been markedly altered in the human chest, and this fact is one which, in my judgment, has not received the consideration to which it is really entitled. These may appear like somewhat positive conclusions to reach on the basis of such a comparatively small number of measurements, but I must explain in defense, if there should be any misapprehension, that this apparent positiveness is merely due to the brevity of the statement which is required.

The next series of measurements which I was able to secure of tubercular chests in any considerable number was at the celebrated Brompton Hospital for Consumption, in London, during a term of research work abroad. For these I am indebted chiefly to the courtesy of Dr. C. Theodore Williams and the members of the attendant staff and the kind assistance of my friend Dr. J. C. Conner. These cases numbered 42, and while taken not merely on the other side of the Atlantic, but also in a different social class from my American series, corroborated its results in a really singular manner. The average index of the 42 cases was 79.6 as compared with 79.5 in the almost identical number of American cases. Through the courtesy of Dr. Rolleston I was asked to present these results before the current meeting of the British Medical Association (1899), and they were published in the *British Medical Journal*, Oct. 28, 1899, and a few months later formed the basis of a chapter in a monograph published about two years ago.[2] This publication was the means of interesting a number of other members of the profession in the question, and I am now able to report a list of 75 cases from Dr. E. H. Colbeck of London, which he has most kindly and generously sent me, taken at the Victoria Park Hospital for Diseases of the Chest. The general average of this is in singularly close accord with the other series, namely, an index of 80.3. The agreement is even closer when the cases of the series which occurred in women, 14 in number, are eliminated, which leaves a male average of 79.3, which is extraordinarily close to my average for the Buffalo and Brompton series, 79.5 and 79.6, respectively. This is the most interesting and valuable series which I have yet received. First, from the fact that it contains a larger number of women, in whom measurements are for obvious reasons much more difficult to secure, and second on account of the large number of cases in an early stage of the disease.

No less than 42 of the 75 cases were in an early stage, and the fact that their average index was 77.6, less than 2 degrees below the average of the whole series, strongly corroborates my tentative view that this shape of chest is a precedent symptom of the disease and not a result.

The series of 14 measurements in women is also interesting as showing a very much higher index than even the already heightened male degree, namely, the average being 84.3. This, of course, is only what one would expect from the well-known greater persistence of the infantile shape of the chest in women, but as to how far it rises proportionately above the average index of the normal female chest I have not been able to secure a sufficient number of measurements to base a statement on.

Two cases in this interesting series are recorded, one as in the very early, and the other prebacillary stage, and as one of these has an index of 83 and the other of 82, it would seem certain that in some cases at least this shape of the chest preceded the disease.

Three other responses have also been made within the past few months to my request for assistance and measurement blanks sent out. The first of them is from Dr. Franklin White of Boston taken at the Long Island Hospital, and these number 35 in all and give an average index of 77.9, nearly 8 degrees above the normal and only 1.6 degrees below the average of my other cases. Of these 10 were in women with a slightly higher index of 78.3, but below the average of the Victoria Park women. Of the 35, five are recorded as in an early stage, and these are an even more striking indication of the pre-existence of this type of chest, in that their index is 79.6, or 1.7 above the average of the series. Dr. White's series is especially worthy of notice from the wide range of extremes in individual cases, not less than 8 of the 35 being at the norm of 70 or below, four of them falling as low as 63 or 64, thus showing that, while the overwhelming majority of tuberculous chests are of high index, the disease is by no means confined to this type of thorax.

The second is from Dr. W. A. Evans of Chicago, who, with Dr. M. G. McHugh, physician in charge of the Cook County Hospital for Consumptives, has gathered together a splendid series of 107 cases with an average index of 80.8. This was published in the *Medical Examiner and Practitioner*, October, 1902, and while it does not give a table of measurements in detail, so that I am unable to analyze it, the conclusions, which are quite fully elaborated, support my own at every point. A small number of cases of early tuberculosis which they have examined shows a high index and they heartily endorse my view, that the persistence of a chest index of over 70 is a sign of arrested development and of greater degree to susceptibility to tuberculosis than that of the normally shaped chest.

A new and valuable addition is made by their series of 38 measurements, taken on inmates of asylums and paupers, not suffering from tuberculosis, and show a much higher index than the normal. This is of great importance, inasmuch as it agrees with both my own measurements on this class, taken at reform schools and other institutions, and also with some measurements made by Dr. Arthur McGugan of Denver, who informs me in a personal letter that he finds this round, prominent type of chest common among the chronic insane. I have long been inclined to regard this type of chest as indicative of general arrest of development, and I should not be at all surprised to find it present in almost as large a percentage of the chronic insane as in those suffering from tuberculosis. To phrase it roughly, one may perhaps be regarded as a physical degenerate who breaks down in the lung, and the other as a physical degenerate who gives way in the brain, and it must also, of course, be remembered that an enormous percentage of the insane (from 30 to 60 per cent.) die ultimately of pulmonary tuberculosis.

---

[2] "Studies in Human and Comparative Pathology," H. J. Glaisher, London, 1901.

Last of all is a series of 35 cases from my friend, Dr. Albert Abrams of San Francisco, which gives an average index of 78, and which he has kindly permitted me to use, although yet unpublished. He, however, inclines very decidedly to the opinion that this shape of chest is due to an emphysematous condition of the lungs, which he has found, and I believe correctly, to be present at a very early stage of tuberculosis, if indeed it does not precede the disease.

This, then, makes a total of over 350 cases of tuberculosis in which chest measurements have been taken, every component group of which gives an index of from 77 to 80.8, the general average being 79.7. This, though still hardly sufficient to base a positive statement on, does certainly seem to me to furnish good grounds for a careful reinvestigation of the question and a defense and justification of the almost unanimous statement in the text-books either on practice or physical diagnosis that the tuberculous chest is flat.

My list of personal measurements is steadily growing and new lists are being sent in to me, from time to time, by the kindness of my friends in the profession, and as soon as I have accumulated 500 or more I propose to send a circular letter to the authors of the standard text-books on physical diagnosis and practice of medicine, asking them to kindly send me the data on which their statements and occasional outlines are based, or failing these, to reinvestigate the subject for themselves.

In the meantime I have prepared printed blanks for recording, with full direction for taking, chest measurements, and shall be most happy to send copies to any of my readers who may be sufficiently interested in the subject to make a few measurements in their wards or clinics. I would be especially grateful for any groups of measurements, no matter how few in number, taken on private patients, the vast majority of my data hitherto having come from the hospital classes. The measurements may be taken with an ordinary pelvimeter or large carpenter's calipers with an inch or centimeter scale; the antero-posterior diameter by letting one point rest on the sternum at the level of the nipple (male), the other on the dorsal spinous process horizontally opposite. The transverse diameter is obtained by sliding the tips of the calipers backward at the nipple level until the widest possible point of separation is reached, behind which they will, of course, begin to approach each other again, then read off the scale; both measurements to be read off in the post-expiratory pause or resting position of the chest.

From the evidence so far presenting, the following conclusions seem to me reasonably probable, though, as before stated, I do not feel justified in advancing any more positive position than this until I have secured at least 500, and preferably 1,000, measurements, taken on all classes and nationalities.

First.—The typical tuberculous chest is round instead of flat and has an average index of about 80, nearly 10 degrees above the normal.

Second.—This type of chest precedes the disease.

Third.—It is an abnormal persistence of the fetal, infantile and child type of chest.

Fourth.—Any chest more than 18 years of age which shows an index of 80 or higher should be regarded as abnormal and as rendering its possessor more than usually liable to tuberculosis.

Fifth.—The occurrence of such a chest in any patient over 18 years of age, suspected of tuberculosis, raises a strong probability of the disease.

Sixth.—The chests of growing boys and girls should be systematically measured at stated intervals, and wherever the index is found distinctly higher than that normal for their age active measures should be taken to remedy the defect.

Seventh.—All those sports and exercises which involve wide-swinging use and play of the arm, chest, shoulder group of muscles, such as tree climbing, swinging from ladders, from rings, from bars, ball throwing, spear hurling, tennis, swimming, will tend to correct this defect and flatten the chest down to its proper index.

These, in fact, are the influences which have made the human-chest shape, and all that is needed to perfect it in the individual is a healthy reversion to the arboreal habits of our prehuman and the war sports of our savage ancestors.

BLOOD PRESSURE DETERMINATIONS IN GENERAL PRACTICE,

INTRODUCING A PRACTICAL INSTRUMENT FOR ROUTINE USE.

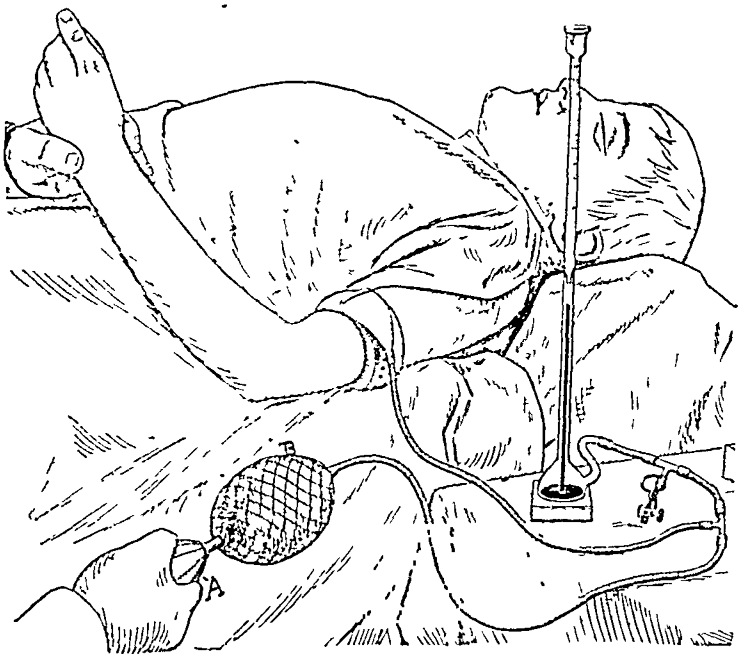
HENRY WIREMAN COOK, M.D.
Resident House Officer, Johns Hopkins Hospital; Late Assistant Resident Physician, Thomas Wilson Sanitarium for Sick Children.
BALTIMORE.

Accurate measurement of arterial tension, which has formed the experimental basis for the physiology of the vascular system since the invention of the kymograph by Ludwig in 1847, has received but little attention from clinicians until of late. The results derived from these laboratory experiments on changes in vascular tension have been appreciated and adopted by the practitioner and form no insignificant part of the *rationale* of his diagnosis and therapy, but while the methods remained of a nature that restricted them to the laboratory they could have no direct clinical application.

Within the past few years several instruments have been devised which have been constructed on a sufficiently practical principle to admit of their extended clinical use. Already the literature relating to clinical blood-pressure observations is voluminous, and one can not glance over a current medical journal without seeing repeated references to this work. From many of the larger hospitals in this country and abroad are coming reports of observations on blood pressure in various morbid conditions, and a vast quantity of valuable material is being acquired which will place arterial tension and its significance in a new light before the medical world. The conception of arterial tension and its therapy must be revolutionized since its determination is removed from the obscure realm of indefinite denomination and per sonal equation to the plane of mathematical accuracy.

It is not the purpose of this paper to give the results of any cumulative work on blood pressure. I have already emphasized the value of routine determinations in stimulation, and in connection with Dr. Briggs will soon give[1] the results of our observations on blood pressure in a variety of conditions occurring in the wards of the Johns Hopkins Hospital. I merely wish here to present the use of an accurate estimation of arterial blood pressure in the wider field of general practice, and to describe an instrument which I have previously referred to,[2] and which I hope may render such determination easier and more practical than is possible by any of the forms of apparatus now obtainable.

My first observations were made with the Gartner apparatus, which, however, proved very unsatisfactory, both for accuracy and ease of application. On account of mechanical difficulties in the instrument itself, and vasomotor changes in the finger of the patient, morbid states involving extreme variations in pressure, such as shock, hemorrhage, toxic hypotension and the hypertension of uremia and apoplexy, could not be followed with any satisfaction, and the instrument is almost inapplicable in the negro and very young children.



The Hill-Barnard apparatus I have not used; first, because I believe maximum pressures to be the best index for systemic force, and this instrument registers minimum pressures only; second, because it requires considerable time and training to manipulate; third, because it involves the use of a spring manometer, which is always liable to be inaccurately gauged and can never be depended on for correct reading unless controlled by a mercury manometer.

The Erlanger apparatus, which combines the principle of the Riva Rocci and the Hill-Barnard instruments, and so gives both minimum and maximum readings, is the ideal for physiologic research; but I found it too ponderous and bulky for clinical work. Messrs. Brush and Fischer used this instrument in the wards of the hospital for some valuable observations on blood pressure in typhoid fever, but it required two men to carry and operate from bed to bed, so was obviously precluded from very extended clinical use.

Dr Cushing had introduced the Riva Rocci apparatus into use at the hospital, and this instrument I found by far the most satisfactory for routine determinations. The principle is simple in the extreme and its practical application easy.

There were several features of the original form of the apparatus which made it inconvenient to handle, such as the complicated arrangement of the mercury manometer and tubing connections and the loose scale, and it also, with other mercury manometers, was so high and unwieldy that it was impossible to carry it to outside visits. The instrument which I present here attempts to apply the Riva Rocci principle in a compact, simple form that will render it serviceable to the general practitioner.

The apparatus consists of three essential parts connected by rubber tubing, a manometer, an arm piece and a bulb with valve attachments. These form a closed air system throughout which pressure is everywhere transmitted equally.

The manometer is entirely of glass, so that readings are not obscured at any point by cork or other jointing. A vertical tube scaled to 350 mm. fits below and projects into a glass reservoir containing mercury. An outlet tube entering the reservoir near the top allows free communication with the rest of the system. The scale, divided into centimeters and millimeters, is etched on the glass, avoiding the possible errors incident to a loose scale behind the glass. The upright tube at the level of 210 mm. is divided by a glass joint fashioned like a ground-glass stopper, the upper end fitting into the lower. This arrangement permits the manometer being packed into a small, easily portable case, and removes the only objection to the mercury manometer, i. e., the amount of space a sufficiently long tube occupies. The lower tube scaled to 210 suffices for all cases except those with marked hypertension, and for the latter it is only necessary to adjust the upper portion. I have considered the mercury manometer as essential for accuracy and reliability in recording pressures. Spring or aneroid devices are always liable to gross errors of adjustment, and require constant control by a mercury manometer. The weight of a certain column of mercury is an absolute quantity, except for the constant fractional variation for temperature.

The arm piece is to transmit the pressure to a peripheral artery of the patient. In estimating pulse tension by finger palpation we obliterate the radial artery by downward pressure against the firmer tissues below. This principle, which was also that of the earlier sphygmomanometers, entails many errors due to position, caliber of artery, thickness of intervening tissues, thickness of arterial wall, etc. The principle of the Riva Rocci method of applying this pressure overcame these difficulties and, according to Janeway, marked the greatest advance in the history of the sphygmomanometer, the one which at once made readings accurate and easily applicable clinically. The pressure, instead of being applied in one direction on the artery, is applied equally around the artery. An extensile rubber bag completely encircles the arm and the pressure is thus transmitted equally through the medium of the tissues to the artery, perpendicular to its wall at every point. This principle minimizes the effect of anatomic and structural peculiarities. The rubber bag is covered by a canvas support with hook and eye attachments, which admits of its being fitted to any size arm.

---

[1] Johns Hopkins Hospital Bulletin, May, 1903.

[2] American Journal of Medical Sciences, March, 1903; Maryland Medical Journal, January, 1903; Johns Hopkins Hospital Bulletin, February, 1903

The rubber bulb by which the operator raises the pressure in the air system and the reservoir bulb are similar to that used in a Paquelin cautery. An outlet tube, guarded by a spring pinch cock, is introduced in the system near the manometer so that the pressure may be released after each reading.

A reading should not take longer than the half minute required for a pulse count, and may be made by any one at all trained in pulse palpation. The band is adjusted snugly around the patient's upper arm as the place of choice, well above the condyles of the humerus. I usually place it almost midway between the elbow and shoulder, though this is unimportant except in very muscular men, where the sharp slope of the biceps in the lower third of the upper arm makes application here inadvisable. The observer then, palpating the radial of the patient distal to the band, quickly raises the pressure in the air system by squeezing the bulb A with the other hand until the pulse is obliterated. This pressure, as registered by the manometer, is noted and the column of mercury allowed to fall slowly until the pulse returns. These two points are confirmed without releasing the pressure, merely varying the column of mercury between them by alternately squeezing and releasing the bulb B. The two points will usually be 2 or 3 mm. apart and the mean between them is the maximum arterial blood pressure. Thus, if the pulse lost at 127 mm. and returns at 125 mm., the reading is called 126 mm.

The minimum pressure as demonstrated by Howell and Brush occurs during the maximum oscillations of the artery wall. These are transmitted to the mercury column and the minimum reading may be determined approximately with this instrument, as described by Gumprecht, by noting the point of maximum oscillation of the mercury column after the tube leading to the bulb B is clamped off.

The only instrument that gives exact readings of minimum pressure is that of Erlanger, and the amount of extra apparatus necessary for this determination makes such an instrument too bulky for routine use. The instrument presented here is intended primarily for maximum blood pressure readings, and only exceptionally will the minimum reading be of clinical significance. However valuable it is in physiologic research to know the exact measure of the pulse wave at every point, what the clinician is concerned in is simply some definite, accurate and easily applicable method of determining what is ordinarily spoken of as pulse force or maximum blood pressure.

It is to be depreciated that at the present time reports of blood pressure observations are appearing in different terms, so that many results seem conflicting. Some give figures of mean pressure, others of maximum, and others of minimum pressure. A single absolute standard for blood pressure nomenclature must be adopted to avoid this difficulty, and I would propose that the maximum blood pressure, as determined by the Riva Rocci principle, be accepted as a standard, and if further details be added that they be individually designated. This question will be more fully discussed elsewhere, but my reasons may be briefly summed up here as follows:

1. Because maximum readings correspond to what has previously been meant by the terms arterial tension and pulse force; that is, the pressure necessary to obliterate the pulse wave, thus to use the same terms for a different pulse quality must inevitably be confusing.

2. A maximum reading requires the least time.

3. It involves a simpler principle and technic, so that it may be safely intrusted as a routine to nurses or other attendants. This has been demonstrated in the wards of the Thomas Wilson Sanitarium and the Johns Hopkins Hospital.

4. It is the more accurate, depending on so definite a quality as obliteration of the pulse rather than the comparatively indefinite point of maximum oscillation of a needle or column of mercury.

5. It is the maximum pressure which is of practical and clinical value and which affords the safest index of actual vascular force. It is during the systole alone that we have the aggregate effect of the elements of circulation. During diastole we merely have a residual effect.

6. An instrument for these maximum determinations can be put in a form so simple and compact that it can become of accurate and reliable routine use in general practice.

I present this instrument because I have found it accurate and easy of application and because it can be made in a simple portable form, which may encourage a more general use of precise measurements of arterial tension.*

The value of blood pressure determination is already sufficiently evidenced by the general interest in the subject, but as yet their application has been almost entirely confined to scientific research in the larger hospitals of the country. This is, of course, a necessary beginning in the new field, for individual observation could be of slight comparative value without its significance had been demonstrated by accumulated evidence. Although those generalizations are a necessary antecedent of more extended use, the chief value of accurate determinations of arterial tension will not be compassed until they are applied in general usage to individual cases. This is true of any method. The results of its scientific application may be great, but while it remains inapplicable in practical usage its limitations are set. Collaborated blood pressure observations have already given us many new ideas concerning the various phases of arterial tension and have cleared many old ones, and as yet the work is only begun; but in a comparatively few years all conditions will have been studied and the deductions drawn, and if the estimation of arterial tension has not become an active, every-day working method in medical practice, its end will have been accomplished. Comparatively little is now being developed on temperature in disease, and yet the clinical estimation of pyrexia dates back but 35 years. But the thermometer will continue always to be one of the most important aids to the profession. And so the value of universal estimation of pulse tension must win general recognition and application. The time is when the practitioner is not satisfied with placing his hand on a flushed brow and "thinking" the patient is feverish, and the time must be when he will not be satisfied with thinking the pulse is stronger.

The pulse is more generally and often appealed to for information than any other one physical sign. Of the elements of the pulse the tension is the most valuable. Since the general introduction of time-recording instruments the rate has assumed the chief position of importance because it can be numerically determined. Ordinarily in critical cases we only ask for the pulse rate because the indefinite sense perception of force is too vague to be trustworthy, yet rate in these cases is chiefly of value as an indication of strength, for experience has taught that a rapid rate often accompanies a weak pulse, and vice versa; yet the fallacy of this generalization is but too often misleading, and it would seem but a poor makeshift to depend on the varying accompaniments of a condition when the condition itself may be determined. Pulse rate undoubtedly often affords a good index of pulse force, but a blood pressure reading is the pulse force. The use of a certain remedy in anemia would gain small credence to-day if cases were reported when the color improved after three days' treatment, while if the hemoglobin increased regularly in that time 40 per cent., it would certainly carry weight. Similarly it would seem almost negligent to *think* a certain treatment lowered the tension in a case of uremia or aneurism, or to give an infusion in shock and be content with *thinking* the pulse felt stronger. The time can not be far distant when operator and anesthetist will keep closer watch of difficult cases by blood pressure observations on the table, when routine blood pressure charts are kept as clinical aids to diagnosis and treatment in hospital wards, when careful case synopses contain blood pressure estimates, and when the general practitioner really *knows* the arterial tension of his patients.

---

* This instrument has been put on the market by Messrs. Eimer and Amend, 205-211 Third Avenue, New York City, in two very satisfactory forms: One, with solid [illegible] manom[illegible]r for hospital and experimental use; the other, [illegible]eter in small portable leather [illegible] the pract[illegible]

Progress in medicine, as in the other component branches of advancing civilization, is not gradual and imperceptible, but is marked definitely by improvements and new departures from the old régime. It would seem that few individual medical advances would be more far reaching or more productive of real benefit than the substitution of precision for vagueness in the estimation of arterial tension.

FURTHER OBSERVATIONS ON INCREASED BLOOD COUNTS DUE TO HIGH ALTITUDE.[*]

JOHN WEINZIRL, M.S.
AND
C. EDW. MAGNUSSON, Ph.D.
UNIVERSITY OF NEW MEXICO.
ALBUQUERQUE, N. M.

That altitude produces an increase in the number of red corpuscles in the blood is a principle very generally accepted. The work of a number of investigators appears to show that the increase is directly proportional to the altitude. At sea level we have, according to Laasche, a blood count of 4,974,000 cells which is by many considered normal.[†] At an altitude of 9,500 feet Egger found a count of 7,000,000 cells; while Viault, who worked in the Cordilleras of South America at an altitude of 14,400 feet, found the high count of 8,000,000 cells. All these counts refer to human subjects.

As a result of these and similar studies the principle of high blood counts in high altitudes is regularly found in our works on hematology, and is regularly taught in the medical schools. Further, more or less elaborate theories have been based on it to account for the beneficial effects ascribed to high altitudes. There appears to have been but little question as to whether the increase in the number of red corpuscles was permanent or merely temporary.

When our first investigations were undertaken, some two years ago, the above principle was naturally accepted; but, after a number of observations had been made, numerous remarkable exceptions were noted. How to explain these observations soon became the leading problem. From a number of blood counts which were made in order to test the accuracy of the altitude hypothesis it was found that in the case of persons resorting to a higher altitude for a short period of time that an increase in the number of red corpuscles usually resulted; but that cases residing regularly at high altitudes showed counts substantially normal. When common white rabbits were transferred to higher altitudes a similar increase followed. The increase was gradual and continued for several weeks, after which the number of cells began to decline. But these experiments were not of sufficient duration to determine whether the blood count would return to normal or remain permanently at a higher figure. The evidence, however, seemed to indicate a return to normal.

In our climatologic investigations it seemed desirable to have this problem definitely solved. For, if no permanent increase in the number of cells occurred then the beneficial effects ascribed to altitude must either be temporary or of a different character. In order to settle this point, at least in our own minds, our observations were continued; a number of animal experiments were also made to bear directly on this problem. The results of these observations and experiments are presented in this paper.

Among a considerable number of cases examined three bear more particularly on this problem and the data taken are therefore given in full.

Case 55 resides regularly in Albuquerque, but while he was spending the summer in a mountain resort, at an altitude of 7,000 feet, we were enabled to make a series of examinations of his blood. He was enjoying excellent health at the time. The period spent in the mountains was 48 days, and although not as long as could be desired, the decrease in the cell count followed the characteristic increase. The counts, together with other data, are embodied in Table 1:

TABLE 1.—BLOOD COUNTS OF SPECIAL CASES AT HIGH ALTITUDES.

Date.	Time.	Weight.	Sp. Gr.	Hemoglobin (per cent.).	Red Cells (per c.m.m.).	Colorless Cells (per c.m.m.).	Time in High Altitude (days).
Case 55..							
7/24/02	10:30	125	1.060	..	5,573,000	12,000	8
7/28/02	10:00	...	1.060	85	6,155,000	12,000	12
7/31/02	2:30	...	.....	..	6,431,000	12,000	15
9/ 4/02	3:00	...	.....	..	5,791,000	11,000	48
12/10/02	10:00	123	1.060	87	5,395,000	14,000	..
Case 75..							
9/20/02	3:00	150	1.061	84	5,093,000	6,000	4
1/27/02	11:30	...	1.061	..	5,382,000	10,000	11
10/ 3/02	11:30	...	.....	..	5,777,000	14,800	17
10/21/02	11:30	...	.....	..	5,928,000	14,800	35
10/31/02	11:30	...	1.062	78	6,280,000	13,000	45
11/20/02	10:00	...	1.063	88	5,591,000	6,000	65
12/11/02	3:45	155	1.061	82	5,218,000	6,000	86
Case 74..							
9/20/02	10:30	177	1.060	82	5,915,000	8,600	4
9/27/02	10:30	...	1.061	..	5,844,000	8,600	11
9/30/02	10:30	...	.....	..	5,564,000	7,400	14
10/ 6/02	11:00	...	.....	..	5,862,000	5,000	20
10/27/02	10:00	...	.....	..	6,271,000	15,000	41
11/21/02	10:00	...	.....	..	5,951,000	9,500	66
12/13/02	11:00	172	1.064	90	6,235,000	6,500	88
12/19/02	11:00	...	1.064	93	6,600,000	.....	94

It is seen that after staying in the mountains eight days the blood count was slightly above normal as indicated by previous examinations. It is also seen that a considerable rise in the number of corpuscles took place and that this occurred rapidly during the early part of his stay. Immediately after returning from the mountains the blood count shows a decrease to practically the original count.

---

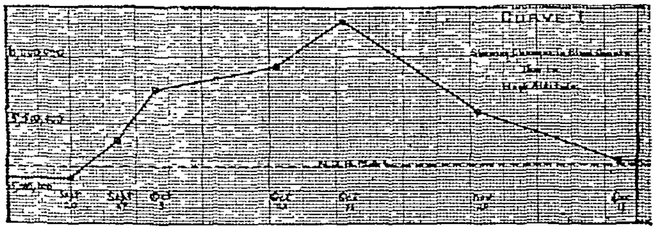
[*] For carrying out the researches embodied in this paper aid was received from the Elizabeth Thompson Science Fund, which is hereby gratefully acknowledged.

[†] In this paper 5,500,000 red corpuscles is assumed to be normal for man and 5,000,000 for woman.

Case 75 was a young man, 22 years of age, who came from the Mississippi valley at an altitude of 900 feet, to Albuquerque at 5,000 feet. The summer had been spent on a farm and the subject enjoyed excellent health. On entering the university as a student regular blood counts were made; the results are given in Table 1. It is seen that the counts increase regularly from 5,093,000 to a maximum of 6,280,000 cells, when a decrease set in and the blood returned practically to the first figure. The difference between the first and last counts, which is slight, can be readily accounted for by the seasonal variations due to temperature. It should, perhaps, be added that this case was particularly free from disturbing factors, which we have found enter largely in much of our work with human subjects. The relation between time spent at the higher altitudes and the number of red corpuscles is shown graphically by Curve 1.

To illustrate the above mentioned fact that external factors may retard, or perhaps even obliterate the effects of altitude, Case 74 is here introduced.

This is a male subject, 30 years of age, and in perfect health. The conditions attending this case are almost identical with those of No. 75. The summer, however, had been spent in recreation, his duties being assumed at about the time the blood counts were begun. These duties were of such a nature as to cause considerable mental anxiety. Undoubtedly this factor, with his resumption of work, had much to do in modifying the usual blood phenomena due to increased altitude. After several weeks the mental strain was largely removed, and, as is seen in Table 1, the characteristic increase followed; but this was after a period of gradual decrease. In other words, there was a decrease when there should have been an increase, and the latter occurred only after a considerable period of time. The case has evidently not yet run its complete course.



Curve 1.—Showing changes in blood count due to high altitude.

In order to meet the conditions of the problem more closely than could be done with human subjects, animal experiments were made. For this purpose four healthy white female rabbits were selected and blood counts made. They were then sent to Ellis' mountain resort (altitude 8,000 feet) and the blood examined after five or six days had elapsed. The animals were allowed to remain at the higher altitude for a period of seventy-two days, when they were returned to the laboratory and again examined. The final count was made after the animals had been kept at the laboratory for one month.

Since changes in physical conditions, such as the character of the food, the amount of floor space, etc., are apt to produce important changes in the blood and so obscure the true phenomena, especial care was exercised in carrying out this experiment. The rabbits were fed on alfalfa, wheat, bran mash and a few vegetables during the time they were under experimentation. The floor space was also kept constant and comprised about 50 square feet. The animals were kept in the open air with an abundance of sunlight. Adequate protection was also given them. The fact that they gained in weight continually while under experiment shows that they were well cared for. Certainly they appeared to be in perfect health.

So far as the writers are aware the only disturbing factor entering into the experiment was involved in the transportation. The greatest care was given them during this time, and it is not believed that the animals could have been materially influenced by it, as the cage was large and the time relatively short.

Rabbit 17 was injured before the end of the experiment, and this affected the counts so as to render them worthless; they are, therefore, excluded. The counts for the other three, together with other valuable data, are included in Table 2:

Table 2.—Blood Counts of Rabbits at High Altitudes.

Date.	Time.	Weight.	Sp. Gr.	Hemoglobin (per cent.).	Red Cells (per c.mm.).	Colorless Cells (per c.mm.).	Days in Mountains.	Days After Return to Albuquerque.

It is observed in rabbits 16 and 19 that the blood counts were very nearly the same on returning as when sent to the mountains; that the intervening blood count was higher; and that the last count, after remaining for one month at the lower altitude, did not differ materially from the one made on returning from the mountains.

Rabbit 18 shows a comparatively low count before being sent to the mountains, while the two final counts are decidedly higher. It is probable that improvement in some physiologic condition occurred, and that this may account for the divergence. The final count is slightly lower than the one made when brought from the mountains, but the fall is not at all in proportion to the fall in altitude. If, then, we take the results as a whole, they agree very well with those shown in Curve 1.

A second experiment with rabbits was carried out, but this varied in a number of details. Three common rabbits were purchased in Las Vegas (altitude 6,500 feet) and sent to the laboratory in Albuquerque. It is seen that one transportation and one change of masters were thus avoided. The rabbits were sent by express and could not have been materially affected by the trip. They were received from Las Vegas in the evening and the examinations made on the following day. The rabbits were in good condition, but were not fat. The results of both examinations are given in Table 2.

In none of the rabbits is there a decrease in the final counts; two agree very well, while the third shows an increase. These data are in harmony with those of the previous experiment, and refute the supposition that high altitudes produce abnormally high blood counts.

To prove that subjects in high altitudes have a blood count substantially normal, it appeared desirable to make examinations of a number of cases who had resided at an increased elevation for varying periods of time. The mountain resort, Camp Whitcomb, at an altitude of 7,000 feet, furnished opportunities for obtaining a number of such cases. The results of these examinations appear in Table 3.

From the table it is seen that these cases do not vary decidedly from the normal. A larger number fall below than above, and this notwithstanding the fact that several must have been influenced by a temporary rise due to the increased elevation of 2,000 from Albuquerque to Camp Whitcomb.

TABLE 3.—BLOOD COUNTS OF CASES RESIDING AT HIGH ALTITUDES.

No. of Case.	Date.	Time.	Weight in Lbs.	Age.	Sex.	Condition of Subject.	Altitude.	Time in Albuquerque. Altitude 5000.	Time in Mountains.	Sp. Gr.	Hemoglobin, per cent.	Red Cells per c.mm.	Colorless Cells, per c.mm.	Red Cells. Above Normal.	Red Cells. Below Normal.

68	7/29/02	10:30	120	28	F	Normal.	7000	6 years	42 days	1.060	75.0	4,773,000	10,000	....	227,000
69	7/29/02	5:00	135	52	F	Normal.	7000	60 days	32 days	1.062	....	5,391,000	10,000	391,000	....
70	7/30/02	10:00	104	40	F	Normal.	7000	2 days	25 days	1.061	78.0	4,942,000	10,000	....	58,000
71	7/31/02	4:15	145	32	M	Normal.	7000	6 years	8 days	1.062	81.0	5,581,000	12,000	81,000	....
72	8/26/02	4:00	115	30	F	Normal.	8000	9 years	60 days	......	....	5,782,000	11,000	782,000	....
73	8/29/02	11:30	120	56	M	Normal.	8000	....	9 years	......	....	5,417,000	7,000	....	83,000

Several of the above cases require comment. Case 56 has been at the higher altitude only thirty days, and therefore had not had sufficient time to pass through the altitude phenomena and return to normal. Cases 57, 58, 59, 62, 64, 67 and 70 were also at the increased elevation during the periods varying from 8 to 30 days, and would likewise be affected by the temporary increase due to a change of altitude. Five of the above cases show blood counts above normal, as was to be expected. It may be mentioned that five of the total number of cases were tuberculous; two of which, however, showed no bacilli. Such cases frequently vary from the normal in their blood counts. They should, however, be affected by the altitude factor in the same way as healthy subjects. If, then, the cases be taken as a whole, they show a substantially normal condition, and support the view that high altitudes have no permanent effect on the number of red corpuscles.

The factor of temperature change has not yet been considered in this discussion. As has been indicated elsewhere,[1] this factor plays an important part in the altitude phenomena as related to the blood. It is there shown that a fall in temperature produces the same effect as an increase in altitude; also, that winter counts are, as a rule, higher than counts made in summer.

If the above data are viewed in the light of these results, it becomes evident why the rabbits taken from a higher altitude did not show a fall in the number of red corpuscles when transferred to lower levels. In both these experiments it happened that when the animals were taken to the lower altitude a considerable fall in the temperature took place; this made the temperature conditions nearly the same in both places, with probably a fall at the lower altitude. Likewise, in the examinations of human subjects recorded above, the temperature factor plays an important rôle. The counts in Table 3 were all made during the warm months of July and August, and therefore show figures lower than would have been obtained during the winter months. They are therefore lower than might have been expected from a consideration of the altitude principle as shown in Curve 1.

From the data presented here we may conclude that the increase in the number of red corpuscles due to an increase in altitude is temporary, and that after the lapse of several weeks the blood counts again become normal. It is believed that the temporary increase is due very largely to the change in the temperature factor, and not to the diminished barometric pressure, as is generally held.

[1] Paper to appear in the American Journal of the Medical Sciences.

American Traveling Medical Schools.—After referring to the traveling post-graduate schools, which we have recently mentioned as being a feature in Germany, the *Medical Standard* says: "In America we already have hundreds of traveling medical 'schools.' Here the practitioner's school is the medical society, which is multiplying with astonishing rapidity. Few medical men are outside of the influence of one or more of these organizations. The county and district societies are frequently attended and addressed by our most distinguished physicians, who often seize these opportunities to demonstrate their clinical methods. In this manner the country practitioner is kept in close touch with the leaders in the profession."

A CASE OF BRAIN ABSCESS

DUE TO LATENT TYPHOID INFECTION; OPERATION; DEATH FROM CARDIAC COMPLICATION.*

G. W. McCASKEY, M.D.
Professor of Clinical Medicine, Fort Wayne College of Medicine.
AND
M. F. PORTER, M.D.
Professor of Surgery and Gynecology, Fort Wayne College of Medicine.
FORT WAYNE, IND.

MEDICAL HISTORY AND DIAGNOSIS BY DR. M'CASKEY.

The following case was referred by Dr. G. M. LaSalle of Wabash, Ind., Sept. 20, 1902:

A. T., laborer, aged 44. His health had always been good up to the time of his present illness, excepting that three years ago he had his nose broken on the left side by a vicious sheep which butted him with its horns. He was not entirely unconscious, but was severely stunned and the nasal bones badly broken, but he apparently recovered from the injury without incident. He said that his present trouble began three months ago, but close questioning elicited the fact that there had been a variable amount of head pain for about five months, which was mostly in the right eye and over the right side of the head. This head pain, undoubtedly, was the initial symptom of the brain lesion which will be described, and gradually increased in severity, so that he had at different times to stop work for a few days because of it.

Three months ago his attention was first attracted to a tingling sensation in the left hand, which was quite persistent, and about the same time noticed that the fingers of the left hand were very weak and evidently somewhat contractured, as he said they were partially closed all the time and that he could not completely open them. This had undoubtedly been preceded by slight paretic weakness, as at that time he would frequently drop things that he was holding in the left hand if of any weight.

He continued at his work, that of straightening sheet iron with a heavy sledge, for about two weeks, when he became disabled and remained so up to the time of my examination. The left hand had grown progressively weaker, until one week prior to my examination, when the weakness increased very rapidly. At that time he had considerable use of this extremity and could raise the hand up over the head, but the paralysis had increased so rapidly during that week that the hand was entirely immobile, the patient being scarcely able to move the fingers. The left leg had also become decidedly weak, and at the date of examination was unable to sustain the weight of the body. Critical examination of the face showed that the motor power of the left side was distinctly less than that of the right, although it was not easily discernible, and was, in fact, very slight.

Four weeks before coming under observation he had a sudden discharge of what, from the description given, was apparently pus from the naso-pharynx. The quantity was quite large and was estimated at from four to five ounces, although the exact quantity was, of course, quite uncertain. This was followed by marked relief of pain, and several times since then there had been slight discharge of a similar material followed by some amelioration of head pain.

The left forearm was persistently flexed on the arm, but by gentle continuous pressure could be completely extended. There was very slight deviation of the tongue to the left; or more correctly speaking, he was unable to push it as far to the right as he could to the left. There was exaggerated knee-jerk and elbow jerk on the left side. The pupils were symmetrical, perhaps a little small, but responded promptly to both light and accommodation.

His hearing was not acute, the hearing distance for a watch being fifteen inches for the right and sixteen for the left, and there had also been double sided tinnitus for a year or more, but the impairment of hearing and "ringing in the ears" were both attributed by the patient, and perhaps correctly, to the deafening noise of his occupation.

The visual fields were perfectly normal in outline and the senses of smell and taste were unimpaired.

There was no optic neuritis, but a distinct increase in the vascularity in the retina on the left side as compared with right. This condition, falling short of optic neuritis, I have several times found, and in examination of some of these cases by oculists but little importance has been attached to it, but I believe that it is a phenomenon entitled to careful consideration. In this case there was every reason to believe that it was the result of the intracranial lesion.

An incident in the case worth noting was typical alopecia areata of about five years' duration.

The analysis of urine revealed nothing of importance. Blood examination showed 6,000 red cells with 90 per cent. of hemoglobin and 13,500 white cells. The increase in leucocytes was made up principally of neutrophiles.

Co-ordination of the eye muscles was perfectly normal, the muscles of mastication were equally strong on the left side as far as could be determined. The patient read ordinary type with either eye without difficulty.

The diagnosis of brain abscess was made, and operation advised and accepted. The patient was operated on September 27 by Dr. M. F. Porter, who, at my request, uncovered the brain cortex at the level of the arm center from just in front of the Rolandic fissure forward, the opening being about one by two inches. This area was selected because of the possible relationship of the injury of three years ago, the pain in right eye, the probable discharge of pus through the cribriform plate of the ethmoid bone, and the certain involvement of the motor zone, as it gave freer access for exploration of the parts thus indicated. The accompanying cut shows the location of the abscess as nearly as it can be determined from the operative procedure, which will be described by Dr. Porter.

Following the operation the patient progressed favorably, there being, as expected, an increase in the paralysis from the operative traumatism. About three or four days after the operation, the patient complained of a little oppression in the upper portion of the chest. His somewhat constrained position rendered necessary from the operative procedure would cause some discomfort, and not much stress was laid on the symptom, although I did examine the chest once with negative results. About 11:30 a. m., October 5, seven and three-quarter days after the operation, after finishing his dinner, he suddenly complained of feeling very ill, became pallid with labored breathing and tumultuous heart action, and almost immediately became unconscious. He was seen by Dr. Porter and myself within twenty or thirty minutes, at which time he had rallied somewhat, the pulse being small and irregular, but he had a dazed expression and the breathing and heart action were still labored, so much so in fact that the heart sounds could not be analyzed at all. A careful examination failed to show any signs of unusual brain disturbance. There was no increase of paralysis, the pupils were symmetrical and normal in size and reaction, the heart disturbance with resulting respiratory embarrassment being the only symptom, to which might be added, perhaps, the temporary unconsciousness and subsequent dazed condition, both of which were undoubtedly the result of an embarrassed heart.

No autopsy would be permitted, but death was due to an acute cardiac lesion very possibly related to the septic process of the brain, probably a septic endocarditis with cardiac atony from toxemia. An antemortem blood clot probably formed in the hea[illegible]nd perhaps had been forming for several days unrecognized. The clinical picture was that of sudden heart failure from such a cause. I have made autopsies in two cases in which death occurred under very similar circumstances; antemortem clots were present in both.

---

* Read before the Northern Tri-State Medical Society, Butler, Ind., Jan. 20, 1903.

Examination of the pus obtained from the brain showed a profusion of rod organisms with the usual microscopic characteristics of pus. No other organisms were found. On careful cultural experiments the organisms showed all the characteristics of the Eberth bacillus, and bacteriologically could not be labeled anything else. No history of typhoid fever could be obtained, but it is well known that many cases of typhoid fever are very mild, and it is more than probable that the patient had been the victim of such an attack which passed under some other name. The typhoid fever organism is well known to be pyogenic in character and has been known in a number of instances to remain latent in the organisms for years and later become virulent with the production of local suppurative or other morbid processes.

The possible relation of the injury on the left side of the nose three years before the examination is a point worth considering. From the history given, the injury appeared to be exclusively to the left of the median line. It does not seem probable that there could have been any actual brain injury excepting by transmitted force. If the infection had been a streptococcus or some of the other more common pyogenic organisms, the possibility of the local infection traveling from the side of the injury to the brain would be more plausible. But it would certainly seem as though the infection must almost necessarily reach the corresponding side of the brain, rather than the opposite one if such a relation existed. The presence of the typhoid bacillus, furthermore, seems to exclude a local infection of this character. That there may have been some contusion of the brain from the injury which lowered the resistance of the brain tissue and made it a prey to the pyogenic processes of the organism which in some manner found its way there is quite possible. Unless such a latent injury can be assumed, and the history at the time of and following the injury does not give the slightest indication of such an injury, the case must be looked on as strictly one of the so-called idiopathic type developing from a latent typhoid infection of unknown date and origin, the latter being in either event sufficient cause for the abscess.

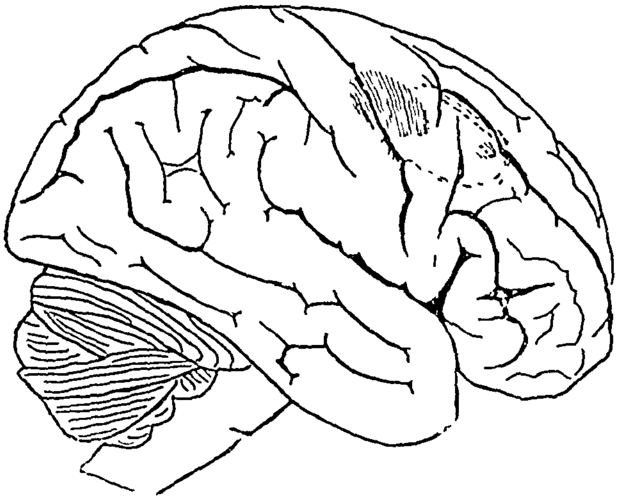

Diagram of right lateral surface. Large heavily shaded area indicates locations of abscess cavity. Small heavily shaded spot, a point at which pus was found in small quantities. Dotted line, area of brain uncovered by surgeon—about 1 by 2 inches.

OPERATION AND REMARKS BY DR. PORTER.

Mr. A. T. was operated on at the request of Dr. G. W. McCaskey, on Sept. 27, 1902, at St. Joseph's Hospital.

The scalp was prepared in the usual way. Dr. E. V. Sweringen anesthetized the patient, using ether. A horseshoe-shaped flap was turned down and a section of bone one by two inches removed by the use of the trephine, Gigli saw and De Vilbiss' instrument. A crucial incision in the dura was made and the flaps reflected. Nothing abnormal could be discovered by sight or touch A small trocar and canula inserted in various directions discovered nothing until a thrust was made in a downward and backward direction at the posterior extremity of the opening in the bone, when the point of the instrument appeared to have entered a cavity, whereupon the trocar was withdrawn and a few drops of pus flowed from the canula. Using the canula as a guide the opening was enlarged and a small soft rubber drain introduced. Thinking the amount of pus removed insufficient to account for all the trouble other areas were explored and we were finally rewarded by discovering a cavity not larger than a pea located at the anterior internal aspect of the uncovered area. This was drained by a strip of gauze. The posterior cavity was about an inch beneath the surface and the anterior one about one half or three-fourths of an inch beneath. All told I do not think the quantity of pus from both cavities would reach 2 drams. The bone was not replaced, the flap was turned back and sutured, leaving only enough opening for the drain. The operation was not followed by shock or any untoward symptom save a slight increase in paralysis such as was expected.

The unhappy ending of the case was, in my opinion, in no wise the result of the operation. This is not the first case in which the exact location of a subcortical lesion was first made known to me by exploratory puncture. A sudden change in the resistance offered to the progress of the instrument, even though slight, is easily appreciated. Had I been using a probe or a needle in this case I would have felt perfectly justified in enlarging the openings, for the sudden lack of resistance offered to the trocar was what first made me aware of the location of the cavities.

On another occasion[1] a subcortical tumor was located because of the increased impediment offered to the progress of the exploring needle by the capsule of the tumor. Exploration by this means is, if carefully done, almost without danger. One's anatomic knowledge should keep him from puncturing large vessels or the floor of the fourth ventricle. Vessels of lesser size may be avoided if, when the needle is arrested by their coats, it is slightly withdrawn and its direction slightly changed. It is to be regretted that no autopsy was allowed.

SHOCK PRODUCED BY GENERAL ANESTHESIA,

WITH RELATION TO DISTURBANCES OF THE BLOOD AND GASTROINTESTINAL TRACT.*

FENTON B. TURCK, M.D.
CHICAGO.

Shock as a result of simple anesthesia in the absence of trauma, hemorrhage or fright has not been carefully worked out. The term "shock" is unscientific. It is the clinical expression for a group of symptoms, the result of failure of important functions of the body, as those of circulation, respiration, excretion and secretion, and general metabolism. A lowered bodily temperature is a more or less constant phenomenon. Shock is intimately connected with the nervous mechanism.

---

[1] The Journal A. M. A., Jan. 25, 1902.

* Read before the Chicago Academy of Medicine, January, 1903, and Chicago Medical Society, March 4, 1903.

In studying shock from anesthesia it is not only essential to consider the specific toxin of the anesthetic used, but the resulting toxic bodies generated through the immediate or more remote influence of general anesthesia. Shock can not, therefore, be expressed in a single definition. The phenomena of shock are so complex that in experimental work on animals it is necessary to study each condition separately, and compile the associated facts obtained and compare them with clinical experience.

The present paper deals with (1) the consideration of the anesthetic as a cellular poison; (2) the disturbances of function as a result of the anesthesia; (3) the toxins that are evolved either from the direct effect of the anesthetic or the disturbances of certain functions of the body.

In experiments on dogs with chloroform and ether, we have not determined the direct toxic effect on cells, as this has been done by numerous observers. Sabaarth,[1] in 1866, reported 119 cases of death from chloroform anesthesia, only 48 of which were due to the toxic effects of chloroform. This led Nothnagel[2] to study the pathologic effects of chloroform and ether on the various cells of the body. Rabbits were chiefly used, and the anesthetics were employed by inhalation, by subcutaneous and intraperitoneal injections, and by direct introduction into the stomach. Doses of different size and at varying intervals were employed. The pathologic findings showed overwhelming evidence of the specific toxic effects of chloroform and ether on cells, whether the animal died from anesthesia or not. Waller's[3] research on isolated nerves showed that their electrical reaction is suspended, or ceases permanently, according to the percentage of chloroform used, and the time of exposure.

In experiments on animals I have frequently noticed that some animals would show evidences of shock more readily than others of the same species, and that even with the most trivial manipulations under anesthesia the animals would die during the same night, the following day or the second day after. They would show all the evidences of shock, as a fall in blood pressure, respiratory failure, lowered temperature, loss of sensation to a greater or less degree, and failure of the excretory organs. This led to the investigation of the question of shock from anesthesia without surgical operation.

METHODS OF OBSERVATION.

Dogs were selected, as they appear more resistant to the after-effects of anesthesia than rabbits and guinea-pigs. Chloroform and ether were used; sometimes they were combined or used alternately. The animal's temperature, pulse and respiration were observed before, during and after the anesthesia, and they were observed sometimes at intervals for forty-eight hours thereafter. The maximum blood pressure was determined, comparisons made, and changes in the blood serum were noted. The condition of the motility of the stomach and intestines was observed. A study of excretion and secretion was made. Where death occurred, a postmortem examination was made. Where shock was evident, the abdomen of some of the animals was opened under local anesthesia. The condition of the splanchnic circulation was determined by direct inspection before external factors brought about any changes, such as might be produced by air, room temperature and manipulations. The serum was secured in some immediately, and in other cases twenty-four hours after anesthesia, by the usual method of bleeding the animal in order to observe any changed condition and its toxic properties. The mucous membrane of the stomach and intestines was dissected out, and both mucosa and muscularis were chopped up separately, to determine the presence of the anesthetic used, by distillation and appropriate tests. The length of time of the anesthesia ranged from one to six hours. A distinction was noted between the immediate or primary effects and those that were remote or secondary.

The conclusions that can be drawn from the details of the experiments made on animals under chloroform or ether are that where shock is produced it does not materially differ from the shock that results from trauma. The most constant pathologic factor is failure of circulation, and this is especially expressed in splanchnic congestion. The failure of temperature and respiration has been considered to be the result of vascular failure, with the corresponding fall of blood pressure.

It will be seen, however, by referring to the Protocols 13 and 15 that the temperature fell several degrees after the injection of the serum, while the blood pressure did not always show a corresponding fall.

Wilson[4] holds that death following chloroform and ether anesthesia is always due to a failure of circulation, and this failure renders the nutrition of vital centers impossible. This would seem to imply that we are dealing with a question of time and degree of circulatory disturbance. White[5] echoes the universal clinical observation that anesthesia always adds to shock. But it is not always recognized that shock itself is often produced by the general effects of anesthesia without trauma, hemorrhage or other etiologic factor.

Kirk[6] has shown experimentally that irregularity of the heart and syncope occur in animals after the last drop of chloroform has left the blood; and it is well known that chloroform and ether may be found in the urine as long as a week after the anesthesia. Horsley[7] demonstrated that death arose from shock to the medullary centers, and that the question of dosage was more of time than amount. The evidences of vomiting, long-continued after anesthesia, are associated with severe circulatory depression, and not infrequently syncope. Ceccherelli[8] experimented on animals with chloroform to determine changes in body temperature, and Angelesco[9] carried out similar experiments with chloroform and ether. They found the fall in temperature was in direct relation to the disturbance of the circulation; that where blood pressure fell rapidly the temperature might fall from three to four degrees F. On the other hand, improved respiration and circulation caused an improvement in the temperature. Duplay and Hallion[10] demonstrated by experiments on dogs, with chloroform and ether, that there was always a fall of pressure under chloroform, also with ether, where the medullary centers were deeply narcotized. From the animals experimented on they concluded that if the failure of the circulation was the direct result of the respiratory failure, as a result of anesthesia, then we ought to expect prompt recovery from the syncope under artificial respiration. But this was not borne out in these experiments. Hill[11] concludes that chloroform paralyzes the splanchnic vasomotor tone, and, at the same time, diminishes the respiratory pump, and shock or fear, he claims, acts like chloroform by its tendency to abolish the compensatory mechanism for the hydrostatic effect of gravity. Hare[12] holds that in overdoses the heart and respiratory centers are paralyzed, and that in the usual proper doses chloroform produces death in the same manner as hemorrhage does, that is, by failure of the respiratory center, because it is deprived of blood, and a pulse failure because the heart has no blood to pump with.

Bland,[13] in comparing the effects of ether and chloroform, shows that chloroform invariably causes a fall in blood pressure, while ether does not except at the end of anesthesia and after narcosis. Hewett[14] claims that surgical shock will occur more readily under ether than chloroform.

The explanations that are usually given for the complex symptoms found in shock from anesthesia can not be explained by the simple failure of blood pressure and respiration, but there appear to be some direct toxic bodies formed that are found in the blood serum. The injection of the serum from animals that have shown evidences of shock produces many of the symptoms manifested in shock, which include loss of sensation, general malaise, marked fall in blood pressure, stertorous respiration and, what is generally more significant, rapid fall in blood pressure. (See protocols.)

Kast and Mester[15] are of the opinion that the blood contains the products of disturbed metabolism, for they found that after prolonged narcosis in healthy individuals a continued disturbance in metabolism of albuminous substances occurred, similar to that in phosphorous poisoning. Becker[16] of Bonn states that there is found in the majority of healthy persons acetonuria of varying duration after narcosis. Boyer[17] found cases of acetonuria with coma and death in from twenty-four to forty-eight hours after operation.

These observations would seem to prove that there are poisonous substances or toxins produced in the serum. The question, however, becomes more complicated when it is remembered that there is a deficiency in elimination, and therefore a retention of toxins. This may be inferred from the experiments of Galeazzi[18] and Grillo with methylene blue. They conclude that the anesthetic lessens the elimination of toxic substances, just as it lessens the elimination of methylene blue. Kemp[19] found that ether causes a rise in blood pressure in the carotid artery, followed by a fall, the urine becoming scant and containing albumin soon after the commencement of the fall in pressure. A similar phenomenon was observed after chloroform; the fall was more gradual, and secretion from the kidneys lessened as the circulation was depressed. Eisendrath[20] found cylindroids and other evidences of damage to the kidneys after anesthesia.

It is clearly evident that the toxicity of the blood may be increased through toxins elaborated by the direct effect of anesthesia, and by the retention of poisonous toxins which are normally excreted.

It is now well recognized that the blood serum normally has the power to neutralize to a greater or less degree toxins that circulate in the blood. One of the important properties of normal serum is its antiferment action, which is shown by the work of Firmi,[21] Roden[21] and Morganroth.[21] Landsteiner[21] shows that the normal blood weakens the fermentive action of pepsin, and Simniczki[22] follows up this work and demonstrates that blood serum has an antiferment action on papayotin; and also, that alcohol weakened or destroyed entirely this antiferment action of the blood.

The writer found that mixing chloroform and ether with normal blood serum lessened the antiferment action of the serum on trypsin in egg albumin. This was demonstrated by the following method: Blood serum was mixed with chloroform and ether and kept in an incubator, after which the narcotic was driven off from the serum, and the serum then mixed with one to two grains of pancreatin and a disk of egg albumin, which it digested completely, while the normal blood serum unmixed with chloroform and ether only softened the disk.

We must conclude that not only the chloroform or ether may possess this property, but an alteration in metabolism may generate a substance that counteracts the antiferment action of the blood.

OBSERVATIONS ON THE BLOOD SERUM.

We next consider the antiferment action of normal serum as compared with serum from animals that have shown symptoms of shock after anesthesia. In the following observations of the relative antiferment action of the sera, the Mett method was used. This consists of simply aspirating egg albumin into a capillary glass tube, 1 to 2 mm. in diameter, and allowing the albumin to coagulate in the tube at a temperature of 95 C. The tube is divided into short lengths and dropped into 2 to 5 cm. of the sera under investigation, with the addition of pancreatin or carica papaya. This is placed in an incubator at 37 C. After a period of twelve hours the tubes are taken out and the length of the undigested column of egg white is measured off by placing on a small glass millimeter scale under a low-power microscope. The difference between the length of the column of undigested white of egg and the length of the tube gives the degree of digestive power of the fluid. The sera into which the lengths of tubes with their albumin contents were dropped were prepared by taking from 2 to 10 c.c. of blood serum from dogs that had been anesthetized and mixing it with 15 decigrams of pancreatin or carica papaya, and this was controlled with normal sera prepared in the same way, the Mett method being then put into practice, as described above.

The following tables show the relative degree of inhibition of the sera to the action of the ferments of normal dog serum, as compared with the sera from animals that have been under chloroform or ether anesthesia.

In order to show the direct effects of chloroform and ether on normal blood serum, the following tables show the findings in a number of experiments performed. The anesthetic was mixed with normal serum and allowed to remain two to three hours, after which the anesthetic was driven off by heat at a temperature of 45 C., aided with a vacuum.

AFTER TREATING WITH CHLOROFORM.

Serum and Pancreatin Mixture.		Digested 10 Hours. Serum and Carica Papaya Mixture.	
5 c.c.	6.1 mm.	5 c.c.	4.1 mm.
2 c.c.	8.2 mm.	2 c.c.	7.2 mm.
3 c.c.	7.1 mm.	3 c.c.	4.3 mm.

AFTER TREATING WITH ETHER.

Serum and Pancreatin Mixture.		Digested 10 Hours. Serum and Carica Papaya Mixture.	
5 c.c.	5.1 mm.	5 c.c.	4.4 m.m.
3 c.c.	3.1 mm.	3 c.c.	5.6 mm.
4 c.c.	6.1 mm.	4 c.c.	5.8 mm.

NORMAL SERA.

5 c.c.	3.2 mm.	5 c.c.	2.4 mm.
2 c.c.	2.1 m.m.	5 c.c.	1.5 mm.
4 c.c.	2.2 mm.		

PANCREATIN, FIFTEEN DECIGRAMS.

Time Animal Was Under Anesthetic.		Time Animal Was Under Anesthetic.	
6 hours	9.0 mm.	1 hour	3.4 mm.
6 hours	8.4 mm.	1 hour	4.3 mm.
4 hours	7.4 mm.		

CARICA PAPAYA, FIFTEEN DECIGRAMS.

Time Animal Was Under Anesthetic.		Time Animal Was Under Anesthetic.	
6 hours	8.8 mm.	1 hour	4.7 mm.
6 hours	8.6 mm.	1 hour	4.1 mm.
4 hours	8.7 mm.		

The blood serum of these animals experimented on also showed a marked hemolytic effect. After shock was evident from anesthesia and the animal was bled, the blood frequently showed a tendency to lake, and this was also noticed where a considerable amount of serum was injected into an animal, the blood showing the same tendency. The following observations show this more definitely:

The serum from an animal that had been five hours under anesthesia, in shock, showed 15 per cent. hemoglobin. When fresh blood was added and centrifuged, the serum showed 50 per cent. hemoglobin.

Blood serum taken from a dog that had been six hours under anesthesia; hemolysis shown in the serum after standing eight hours; 4 c.c. of this serum added to 5 c.c. of fresh blood produced laking immediately in the test tube; .015 of blood in 4 c.c. of serum also produced laking. Hemoglobin in serum, 10 per cent.; after adding fresh blood and centrifuging, it was raised to 15 or 20 per cent.

Microscopic slide irrigated with shock serum and one drop of normal blood; placed in incubator; shadow corpuscles formed.

Agglutinization.—Serum from an animal that had been under anesthesia for three hours; one drop of blood under slide irrigated with serum showed immediate clumping. When blood from an animal six hours under anesthesia was used, the same condition was observed after the fourth and fifth dilutions.

Precipitins.—Immediate coagulations of blood have been frequently noted after prolonged anesthesia when the blood was withdrawn. One drop of normal blood added to 5 c.c. of sera showed coagulation within two minutes after having been placed in incubator. Equal parts of shock serum with normal blood showed immediate clotting of the whole mass.

The following condensed table represents the effect of serum taken from dogs which had been under the influence of chloroform or ether from one to six hours:

SERUM FROM CHLOROFORM.

	Hemolysis.	Agglutination.	Precipitins.
6 hours.......	Positive.	Positive.	Positive.
5 hours.......	Positive.	Positive.	Positive.
4 hours.......	Positive.	Positive.	Negative.
2 hours.......	Slight.	Plus minus.	Negative.
1 hour........	Slight.	Negative.	Negative.

ETHER.

	Hemolysis.	Agglutination.	Precipitins.
6 hours.......	Positive.	Positive.	Positive.
5 hours.......	Positive.	Positive.	Positive.
4 hours.......	Positive.	Positive.	Positive.
2 hours.......	Slight.	Negative.	Negative.
1 hour........	Not constant.	Negative.	Negative.

These experiments suggest the explanation of the cause of death in animals that have been in shock from the after-infection with saprophytic germs, which, without the shock, would have proven negative. Experiments made by the writer,[23] which have been previously published, show that the *Staphylococcus albus*, *Staphylococcus pyogenes aureus*, and the colon bacillus were equally prompt and positive in their toxic effects when injected after shock. The *Staphylococcus albus* and colon bacillus, when injected into normal animals used as controls in these experiments, gave negative results.

EFFECTS OF CHLOROFORM AND ETHER ON THE STOMACH AND INTESTINES.

We have still to consider another source of toxemia and irritation that follow the use of anesthetics when administered only for a short period. I refer to the disturbances that arise from the gastrointestinal tract following narcosis. That anesthesia from chloroform or ether interferes with the functions of the stomach and intestines is, I think, admitted by all clinicians, but just what disturbances occur is not always made clear. These disturbances include those of motility and secretion, as the direct result of the anesthesia and the splanchnic congestion.

The local effect of the anesthesia is shown in the following experiment:

The animal's esophagus was plugged to prevent the swallowing of chloroform or ether, and this was found to be quite as effective as tracheotomy for the purpose of administering the anesthetic through the tracheal opening. On examining the stomach through a fistula, previously produced and after gastric lavage, there was found an initial increase in the flow of hydrochloric acid, followed later by a diminished production of hydrochloric acid and ferments and the formation of a large quantity of mucus, which is always the product of irritation. Chloroform and ether were found in the wash water, they being recovered by distillation and the usual tests.

The fact that local irritation causes an initial rise in the formation of hydrochloric acid was first noted and published by the writer in 1894.[24] It was subsequently demonstrated by him in 1895[25] and in 1896,[26] and can be found by referring to the literature of his experiments with nitrate of silver, tannic acid, mustard and many other substances used in experimental acute and chronic gastritis. This initial rise in the formation of hydrochloric acid and pepsin was invariably followed by a decrease in their formation, and a corresponding increase in the formation of mucus, until subsequently no hydrochloric acid or ferments were secreted. It is, therefore, surprising to find that Pawlow[27] of St. Petersburg, in his recently published work, claims that these phenomena were first observed in his laboratory, and were the result of the observations of Sawrieu,[28] in 1900, which is six years after my observations, published both in this country and Europe.

It seemed desirable to determine whether the mucous membrane of the stomach and intestines contained ether or chloroform after anesthesia. To demonstrate this point, mucous membranes and muscle walls were examined separately. The stomach was washed out after a narcosis of two or three hours' duration, and the mucous membrane dissected from the muscle walls of both stomach and intestines. These were placed in separate receptacles and finely chopped. After thorough maceration, the products were distilled, and it was found that both muscle walls and mucous membranes contained a considerable amount of the anesthetics used. (The chloroform test is benzoisonitrile, C_7H_5N.) Ether was detected after distillation by the odor.

With both chloroform and ether, even after one hour's anesthesia, there was a distinct reaction for both found in distillation, but after two hours it was much more marked and distinct, and where six hours' anesthesia was used, the reaction was very much increased. In some of the experiments the mucous membrane was removed several hours after the effects of the anesthesia passed off, and still the anesthetic could be detected in the mucous membrane. The irritating effects of these would seem to account for the large amount of mucus produced, which is referred to above.

The writer has also found that constant irritation of the mucous membrane with substances, such as ether and mustard, if continued for any length of time, or if large enough in quantity, produced marked disturbances of the circulation. This was demonstrated in the experiments reported in my paper,[29] read before the American Gastro-Enterological Association, at Washington, D. C., in 1900. This is in conformity with the observations of irritations of mucous membrane that may affect the heart and circulation reflexly. Kionka[30] found that ether exercises an irritating action on all mucous membranes, even on those with which it has not been brought in direct contact. Guinard,[31] by experimental research in narcoses, found that any irritation of the intestines caused by reflex action arrested respiration and circulation. Guirni[32] observed that irritation, which may arise from mucous membranes affecting the pneumogastric and other nerve filaments, is more strikingly observed when the nasal mucous membrane is irritated, and may cause an inhibition of the heart's action. Rosenberg[33] suggested the application of 10 per cent. solution of cocain to prevent this irritation. It was suggested to the writer to use applications of cocain over the area of the stomach and intestines, with a view to blocking the irritation that might arise from the anesthetics.

Meyer and Prebrium,[34] in 1873, showed the reflex effect of gastric irritation on the heart, causing inhibition.

When it is remembered that vomiting and disturbance of the circulation are usually associated with anesthesia, and that the removal of the ether from the stomach by lavage will check the vomiting and frequently stimulate the depressed circulation, it is evident from both scientific and clinical observations that this reflex irritation is a very potent factor in the production of the symptoms of shock following anesthesia. This is strengthened by the observations of Brunton,[35] who found that chloroform taken internally produces vomiting, and that even though coma and death be averted, the irritations of the stomach and intestines continue and produce the evidences of circulatory depression analogous to shock.

It is therefore evident that the atony which is noticed clinically may have some relation to the degree or quantity of anesthetic that is found in the walls of the stomach. The anesthetic used and the resulting toxic condition may act similarly to the toxic effect of fatigue stuff. This, with the effect of the anesthetic on the nerve centers, producing splanchnic congestion, may account for the lack of motion in the stomach and intestines. This atony results in the accumulation of gases in the stomach, and gases that are found normally in the stomach will distend it when the tone of the muscle wall is diminished or lost. Experimentally, through a gastric fistula, with the pylorus and cardia tied off, I have found that after the stomach has been emptied of its gases, the formation of gas in the stomach continues, which could not have been the result of fermentation, but must have been due to the gases from the blood. The great distension that is sometimes noted soon after prolonged anesthesia produces considerable effect on the splanchnic circulation.

Meyer and Prebrium[35] observed that distension of the stomach caused a rise in blood pressure. The writer's observations, previously published, were that the initial rise was followed by a fall in blood pressure, especially if the distension was chronic or prolonged. The disturbance of the circulation, as the result of atony and distension, must constitute a very important factor in anesthesia, and as long as there is a disturbance of the splanchnic circulation we must expect a disturbance of the motor power of the stomach and intestines.

It must also be remembered that where there is a lack of motor power with retention the excretion of chloroform and ether into the stomach seems to increase the toxicity of the stomach contents. From this we would deduce the observation that chloroform and ether either form a new compound or have the power of dissolving out the toxic principles that are readily absorbed. The injection of the normal stomach contents does not produce such toxic effects up to 40 c.c.; whereas in atony of the stomach, especially after chloroform or ether anesthesia, the toxicity of the stomach contents is markedly increased. The increased bacterial growth and the formation of toxins in gastric atony have been repeatedly shown in the author's literature of the past eight or nine years.

SUMMARY.

The complex clinical picture of the after-effects of chloroform or ether anesthesia is made more clear by experimental research, from which we may deduce the following facts:

1. The circulatory disturbance is a direct result of the chloroform or ether acting on the vasomotor centers.
2. The prolonged effect of chloroform and ether on the splanchnic circulation results in congestion associated with fall in temperature. Temperature may fall without fall in blood pressure.
3. The direct effect of the toxins of chloroform and ether acting on cells, with disturbance of metabolism, may produce toxic products.
4. The resulting elaboration of toxins produces symptoms of "autointoxication," associated with the formation of hemolytic and agglutinating bodies, and precipitins.
5. Indirect toxic effects result from retention of toxic products through disturbances of elimination.
6. There is lessened resistance of the blood serum to normal excreted toxins.
7. There is lessened resistance of the blood serum to bacterial toxins.
8. There is diminished resistance to the development of saprophytic and pathogenic micro-organisms.
9. This may be partly explained by the changes observed in the sera, such as diminished antiferment properties, hemolysis, agglutination, precipitins, etc.
10. That reflex effects result, such as reflex irritation set up by the excretion of the anesthetic into the stomach and intestines.
11. As the result of atony there is the formation of toxins in the stomach and intestines through bacterial growth.
12. Atony of the stomach and intestines results in the accumulation of gases and interference with the circulation.
13. There is increased toxicity of the stomach contents in the presence of chloroform and ether.

PROTOCOLS.

EXPERIMENT 1.—Dog; fox terrier, mongrel; weight, 11 kilograms. Ether anesthesia, by inhalation. Rectal temperature, 39 C. Time, six hours. Maximum blood pressure obtained by the modification of a Riva-Rocci "tonometer," 130-140 mm. At the end of three hours temperature 36.1 C. Blood pressure, 90-95. At the end of four hours the rectal temperature was 35 and the blood pressure 70. At the end of five hours blood pressure is 65-70. The rectal temperature 35. Six hours, 60-70; rectal temperature, 34.8.

Anesthesia removed. Twenty-four hours after: Blood pressure, 110; rectal temperature 36.5. Animal bled from carotid; coagulation prompt.

EXPERIMENT 2.—Dog; curly, black mongrel; weight, 20 kilograms. Rectal temperature, 39 C. Ether anesthesia, by inhalation. Time, six hours Ether removed at intervals, and as soon as dog showed evidence of recovery, the anesthetic was again administered. After four hours, the animal showed marked depression. Rectal temperature, 36 C. Respirations weak. Anesthetic removed. After four hours and thirty minutes, slight movements, but no return of consciousness. Reflexes returned. After four hours and forty-five minutes, animal awoke. No activity. Rectal temperature, 35.8 C. After five hours and ten minutes, anesthetic administered. Rectal temperature 35.5.

C. Shallow respiration. Five hours and twenty minutes, anesthetic removed. Marked depression. Five hours and fifty minutes, anesthetic administered until sixth hour. Rectal temperature, 35.2 C. Respirations shallow; blanched surface; gums pale; rapid, weak pulse.

Animal put in warm place; twelve hours after the removal of anesthetic, rectal temperature was 36.5 C.

Clinical symptoms of "shock." Refuses to eat; will drink; very listless; extremities cold; weak, with occasional trembling. Again placed under ether. Carotid opened, and secured 850 c.c. of blood, which shows rapid coagulation.

Experiment 3.—Dog; curly, black; weight, 16.2 kilograms. Anesthesia, chloroform. Five hours. Temperature at the beginning was 38.3 C., by rectum. Blood pressure, 120. In one hour, temperature, 37.2. At the end of four hours temperature was 35. Anesthesia removed. Animal shows no sign of awakening. Four hours and thirty minutes after, temperature, 37. Chloroform was then used. Five hours, temperature 36. The animal was placed in a warm location. Twenty-four hours afterward temperature was 36.5. Refused to eat; marked depression; blood pressure, 90. The animal was bled; recovered 550 c.c. of blood. Coagulation prompt.

Experiment 4.—Dog; mongrel bull terrier. Ether. Weight, 18.5 kilograms. Blood pressure, 150. Temperature, 38.6, rectum. At the end of two hours, the blood pressure was 95 to 105. Temperature, 37. Four hours, blood pressure, 78; temperature, 36.1. Animal placed in warm place. Twelve hours after rectal temperature, 36.5; blood pressure, 90-95. Animal bled; recovered 380 c.c. Coagulation prompt.

Experiment 5.—Dog; black and white, mongrel; weight, 18 kilograms. Blood pressure, 140; temperature, 38.3. Chloroform. At the end of three hours, anesthetic removed; temperature 35.6; blood pressure, 90-100. Twelve hours afterward, temperature 37.5. Blood drawn, 500 c.c.

Experiment 6.—Dog, mongrel; weight, 17 kilograms. Blood pressure, 130. Temperature, 38. Ether anesthesia. At the end of two hours changed from ether to chloroform. Pressure, 100. Three hours, pressure, 80. Anesthetic removed. Twelve hours afterward, removed 600 c.c.

Experiment 7.—Dog. Chloroform anesthesia, two hours. Blood removed at once after the anesthesia. Recovered 650 c.c. Coagulation prompt.

Experiment 8.—Dog, mongrel pointer; weight, 12.5 kilograms Blood pressure, 130-140. Temperature, 38.5. At the end of four hours, blood pressure, 60-70. Anesthetic removed. Twenty-four hours, blood pressure 100-110; temperature, 37.2. Animal bled; 550 c.c. Coagulation prompt.

Experiment 9.—Dog, black setter; weight, 15 kilograms. Anesthesia, chloroform; two hours. Temperature, 38.5; at the end of two hours, 36. Removal of anesthesia one hour afterward; animal bled; 600 c.c Coagulation.

Experiment 10.—Dog, white and black mongrel; weight, 9.5 kilograms Temperature, 38. Animal under anesthesia three hours. Temperature, at the end of this time, 36.1. Twenty-four hours afterward temperature 37.2; 600 cubic centimeters.

Experiment 11.—Dog. Anesthesia, chloroform; two hours. Temperature, 38.4. At the end of four hours, temperature 35.5. Blood removed the following day. Coagulation.

Experiment 12.—Dog, black and tan; weight, 6.8 kilograms. Ether, one hour. Temperature at the beginning, 39, and at the end of one hour, 37 7. Removed blood five hours afterwards. Coagulation not prompt.

Experiment 13.—Dog; weight, 15 kilograms; temperature, 38. Normal blood pressure taken at 11:20. Injection of blood serum from animal that had been five hours under anesthesia. Blood was removed one hour after the end of anesthesia: Injected into jugular vein, 11:20, 25 c.c. serum; 11:30, 15 c.c. serum; 11:35, 20 c.c. serum; 11:45, 25 c.c. serum. At 12 o'clock the temperature was 36.1; 12:20, 35. No marked fall in blood pressure; 12:30, 33.4; tongue pale; surface cold; marked twitching; 1:15, temperature inside the tissues, 33.2. Blood withdrawn, 700 c.c. Coagulated at once.

Experiment 14.—Dog, mongrel pointer; weight, 17 kilograms; 4 p. m., blood pressure, 140-145. Kymographic tracings. Anesthesia, chloroform. Injected serum from dog, removed twenty-four hours after anesthesia, which had been continued for six hours. Twenty minutes after this injected 25 c.c. of serum. 4:30 p. m., 50 c.c. of serum injected. Blood pressure, 110; 25 c.c. injected; blood pressure, 80. At 6:05 p. m., 30 c.c. injected; pressure, 57-60. Chloroform anesthesia changed to ether; blood pressure rose 20 mm. Again dropped to 50. Anesthetic was withdrawn, aseptic dressings applied, and dog put in a warm place. Result, death in six hours.

Experiment 15.—Dog, black and white mongrel; weight, 17 kilograms. One grain of morphine injected at 10 a. m.; 10:45, ether anesthesia. Normal record. Injected into jugular serum taken from a dog twelve hours after anesthesia which had lasted four hours. Rectal temperature, 39; 11 a. m., injected 10 c c. of serum; 11:10, 20 c.c.; 11:20, 15 c.c.; 11:25, 10 c.c.; 11:30, 30 c.c.; 11:35, 30 c.c. Total amount of serum, 105 c.c. Temperature, 35.2. No marked fall in blood pressure Changed anesthesia to chloroform, with a marked fall in blood pressure.

Experiment 16.—Mongrel, placed under ether anesthesia; pressure, 140; kymographic tracings. Ether. Temperature, 41. Injected 90 c.c. serum from dog which had been under anesthesia for five hours. The serum had been removed the following day. Blood pressure fell 80 to 70; forty-five minutes, temperature 36 C. Coagulation marked, interfering with further blood pressure records. Anesthesia removed; animal placed in warm location; temperature following day, 37 C. After three days, animal still showed symptoms of shock. Died on the third day. Post-mortem revealed no evidence of infection. Cultures negative.

Experiment 17.—Small black and tan under chloroform. Blood pressure, 130. Serum used from a dog which had been under anesthesia five hours, and bled the following day; 25 c.c. of serum injected. Fifteen minutes, pressure fell to 115; twenty minutes, 110; thirty minutes, 95; in one hour, 25 c.c. serum injected. Blood pressure, 15 minutes, following the last injection, 65-70. Wide excursion. Anesthesia removed. Animal died the following day.

Experiment 18.—Mongrel bull. Ether anesthesia. Blood pressure, 150. Serum from an animal that had been under ether for four hours. The animal had been bled immediately after removal of anesthetic. Injections of 22 c.c., followed by another injection of 22 c.c. No effect on blood pressure, 20 c.c.; no effect on blood pressure, 20 c.c.; pressure, 100. In one hour, pressure 85. Anesthetic withdrawn, and animal recovered.

Experiment 19.—Dog, mongrel; weight, 15 kilograms; blood pressure, 130; temperature, 29 C. Serum used, removed the following day from an animal that had been three hours under anesthesia. 80 c.c. injected. After a period of fifteen minutes, pressure 90-100. One hour and fifteen minutes, pressure ranged from 90 to 100. Temperature, 38. Animal recovered. The following day the temperature, 39.4.

Experiment 20.—Dog, mongrel. Serum taken five hours after ether anesthesia, which had continued for two hours. Blood pressure, 135; after injection of 90 c.c., blood pressure, 100. Anesthesia changed to chloroform. Blood pressure, 90. Ether again administered, pressure 110. Ninety minutes, pressure 90-95. The following day the animal bled; removal of blood, 550 c.c.

Experiment 21.—Fox terrier; female. Temperature, 39.4. Injection of serum taken from dog twelve hours after two hours' anesthesia; 16 c.c. injected, with a fall of blood pressure, followed by a chill as soon as the anesthetic was removed. At the end of one hour temperature was 37.3; one and three-quarter hours after, 37.2. Animal placed near a warm room, and continued in a condition of shock, and died six hours afterwards.

Experiment 22.—Dog, yellow; temperature, 38.8. Injected serum from an animal six hours under anesthesia. Temperature, 38 3. Amount injected, 25 c.c. and 20 c.c. Temperature went down to 37.2. The following day rectal temperature 38.3. Animal listless; can not be aroused, and lips appear pale; marked loss of sensation. Second day, temperature 39.5. Animal depressed; marked loss of appetite. Fourth day, animal bled; shows rapid coagulation and laking.

THE HEMOLYTIC EFFECT, AGGLUTINATION AND PRECIPITINS OF BLOOD SERUM FROM ANIMALS AFTER PROLONGED ANESTHESIA.

EXPERIMENT 23.—Dog. After five hours' anesthesia blood was taken from the carotid; shock evident from low blood pressure; temperature 97; shallow respiration; collapse imminent fifteen minutes after the removal of anesthesia. Blood shows a tendency to lake, with almost immediate coagulation. Blood placed in refrigerator for twelve hours, obtained 110 c.c of serum; hemoglobin (Fleischl), 10 per cent. One measure of Fleischl (7.65) added to fresh blood centrifuged showed twenty to thirty per cent. hemoglobin. The addition of 5 c.c. to 1 c.c. of fresh blood hemolysis within five minutes well marked, with "ghosts" floating in the serum. One-half c.c. of fresh blood, with 5 c.c. of serum, diluted two volumes with normal salt, hemolysis shown within five minutes. Four c.c. of serum added to 5 c.c. of blood showed immediate laking.

EXPERIMENT 24.—Dog, female pointer; weight 18 kilograms. Five hours under chloroform. Anesthesia removed, and animal allowed to recover from the anesthesia. Five hours later blood removed, 160 c c. of serum obtained after standing eleven hours. Serum tinged, showing 8 to 10 per cent. hemoglobin. By adding fresh blood serum, 20 to 30 per cent. hemoglobin after centrifuging. One c.c. of fresh blood, 5 c.c. of blood serum, immediate laking; incubator five hours, marked hemolysis; hemoglobin (Fleischl) 100 per cent.

Microscopic slide with serum taken from dog under anesthesia, one drop of normal blood, showed shadow corpuscles.

EXPERIMENT 25.—Bull pup, female; weight 20 kilograms. Blood pressure taken with kymograph; injected 90 c.c. of blood serum taken from an animal that had been under anesthesia for five hours. This animal was placed under anesthesia for one hour only, and injected; no marked fall in blood pressure. At the end of one hour blood was withdrawn and obtained 80 c.c. of serum. One drop of normal blood with 5 c.c. of serum, showed hemolysis within five minutes. Equal quantities of blood and serum showed marked laking. One drop of normal blood irrigated under slide with serum placed in incubator showed shadow corpuscles. Blood serum, to which is added fresh blood (7.65 c.c.), increased the hemoglobin from 15 to 20 per cent. after centrifuge.

EXPERIMENT 26.—Dog. Under anesthesia two hours. Withdrew serum and blood, and after twelve hours serum clear. Adding one drop of normal blood does not produce any marked discoloration after centrifuging, only slight discoloration. Equal parts of normal blood serum produced slight laking. Irrigating one drop under microscope; after thirty minutes in incubator clumping is observed; no marked ghost or shadow corpuscle.

Serum taken from a dog that had been under chloroform for three hours; one drop of normal blood mixed with serum from an animal that had been under chloroform showed immediate clumping. Coagulation took place within five minutes, with 1 c.c. of blood added to 5 c.c. of serum

Animal six hours under anesthesia; ether used; serum obtained the following day. Added normal blood to such serum produced immediate coagulation. Adding one drop of normal blood produces immediate clumping. Fourth dilution with normal salt solution, 10 c.c.; added 1 c.c. of normal blood, coagulation with laking.

One drop of normal blood added to 5 c.c. of serum after four hours' anesthesia. Equal parts of blood with serum obtained during profound narcosis after four hours.

ANTITOXIN AND THE PHARMACOPEIA.

PLEA FOR THE ADOPTION OF A TEST WHICH IN THE AUTHOR'S EXPERIENCE PRESENTS THE LEAST DIFFICULTIES.

WILLIAM R. HUBBERT, B S., M.D.
DETROIT.

The proposed admission into the Pharmacopeia of antitoxin for diphtheria in accordance with the resolutions of the committee appointed to confer on the subject, means, if finally admitted, the necessary adoption of a suitable standard for testing which shall be at once comprehensive, and yet so simple, to use the trite expression with reference to the introduction of tests into that most important work, one "that any intelligent pharmacist may be able to apply." While I am much in favor of the recognition by the Pharmacopeia which this most important biologic product rightly deserves, I am in favor of the adoption of the simplest test which shall show not only the number of units present in any bulb of serum, but one which can be performed within the shortest possible time in any pharmacy in the land and by a person not necessarily experienced in biological work.

There is so little known on this subject of testing antitoxin, outside of a few laboratories in the land, that it is necessary to describe in detail the methods used in testing before one can take up the consideration of the simplest method. Down to a comparatively recent time it was supposed that if a definite amount of serum had neutralized a hundred least fatal doses of toxin, which least fatal dose had been determined by injecting varying amounts of the filtered toxic solution in which the diphtheria germs had been grown, into 250 gram guinea-pigs, it was supposed that a like amount of the same antitoxin would always neutralize 100 least fatal doses of toxin from whatever source the toxin was obtained. Accordingly, Ehrlich defined a unit of antitoxin to be the least amount of antitoxin which would neutralize a hundred minimal fatal doses of diphtheria toxin. This definition remained the accepted one for some little time and either 10 or 100 m.f.d. were used in testing antitoxin the world over; but Ehrlich found by testing a number of different toxins obtained from different sources, either grown from the same or from different cultures, or using old toxins in comparison with new ones, that there was a vast discrepancy in the re-

such products as toxins, serums and vaccines. This standard toxin, put up in ounce bottles whose L+ had been definitely determined, could be furnished each laboratory in the country or could be procured by any pharmacist who wished it, and from it with a few guinea-pigs and simple apparatus for measuring doses, an estimate could be made of the antitoxic value of a given bulb of serum which would come within 5 per cent. of being correct. Such a test would, in my opinion, be the simplest that could be devised that would give any approach to accuracy in results, and all serums tested with it, no matter where manufactured, would correspond in antitoxic units and the product be uniform. But if the pharmacist had to procure a standard antitoxic unit and from this not only determine the L+ of his toxin, but also the value in Ehrlich units of the given serum, the difficulty would be thereby very greatly increased and the results correspondingly unreliable.

I make an appeal for the adoption of the above method of test, for I know from years of experience how difficult it is to get uniformity where the calculations are increased. Then, too, there is such a chance for individual error to creep in that any effort to lessen this factor ought to be given consideration by the committee. Then, again, we ought to adopt a system that is American instead of one that has been imported, if the American can be proved to be just as reliable. There is such a great variation in the antitoxic value of the different serums on the market that it seems to me some uniform method of test should be adopted. This laboratory with which I am connected is willing and anxious to adopt any system of test which the committee in its judgment may recommend.

In conclusion, allow me to state that I am in favor of the adoption of the Ehrlich standard unit by the committee, but in the practical working out of the scheme I urge the adoption of a standard toxin based on the standard unit, which standard shall be maintained in some laboratory, preferably a government laboratory, and that this standard toxin shall be supplied to all laboratories producing antitoxins, or to any pharmacist desiring to make tests. I urge this in the interests of a more uniform product and also on account of its simplicity.

SOME EXPERIENCES WITH THE *X*-RAY AS A THERAPEUTIC AGENT.

REPORT OF THE CURE OF A CASE OF ALVEOLAR MELANOTIC SARCOMA.*

EDWIN WALKER, M.D., Ph.D.
EVANSVILLE, IND.

To Finsen belongs the credit of first studying in a scientific manner the therapeutic action of light. His remarkable results and earnest work have opened up a most promising field. The discovery of the Rœntgen rays, and the scientific study of these, with the Becquerel and violet rays, have further stimulated thought and research.

We now know that the spectrum we see is only about one-eighth of the real one, and that in the dark field there are numerous other rays which possess remarkable chemical and photographic reaction. What effects these will have in the cure of disease none can imagine, but certainly the effect of the Rœntgen ray in some hitherto incurable maladies gives reason for great hope.

It is not my purpose to go into the general discussion of the treatment of cancer by the *x*-rays. Many interesting articles on phototherapy have been published in our recent literature, but the whole work is so new that we can only glean from them the most general principles. It would be hardly profitable to review them at this time.

I will give a brief outline of my own observations in the effects of *x*-rays on malignant disease.

In the fall of 1901 I was consulted by a physician who was suffering with a post-peritoneal malignant growth. At his request, we took a skiagraph, which required a twenty-minute exposure. He returned a few days later, saying that he felt much better and that he believed the growth was smaller. Our examinations did not confirm this observation, but, at his request, six or seven applications were made at intervals of a week, and for a while he thought he was much better. The disease, however, advanced to a fatal termination.

In this case my confidence in the therapeutic value of the ray was so little that I did not pursue the treatment with any enthusiasm, but as I look back to it now, after further experience, I really believe that it did do some good, and that a more vigorous treatment might have yielded better results.

The case which I desire especially to report was so remarkable in its course and termination as to be for me an epoch in my professional life. No previous experience has produced so profound an impression. To see a rapid-growing sarcoma heal in a short time under any treatment is truly extraordinary. Such patients are doomed in spite of any known application of remedies. Here was a man grasped from certain death before my very eyes—can you wonder at the deep impression made?

The fortunate subject of this sketch was Jacob Saelwachter of Wadesville, Ind. He was 31 years of age and a farmer. He came to me Feb. 20, 1902. On the right cheek, just in front of the ear, was a black tumor protruding from the surface, one and a half inches in diameter There were no enlargements of the glands in the neck. Under cocain anesthesia, the growth was excised well out into healthy tissue. The wound was united with silkworm gut sutures. It never healed.

Evidences of return could be seen in two weeks, small black spots appearing about its edges, and about this time an enlargement appeared under the angle of the jaw, which grew with great rapidity.

March 22, under general anesthesia, I made a second operation, excising the old wound widely. The incision was continued to the neck, and I removed the tumor, which had extended deep down between the vessels to the vertebra. The sterno-cleido-mastoid muscle was infiltrated for more than an inch. The diseased portion was thoroughly excised. At various points in the bottom of the wound black places could be seen. These were curetted, only to reveal the greater depth of the infiltration. The operation had lasted nearly an hour, when I concluded the complete removal was impossible. The wound was packed with gauze. There was no infection, still it was soon evident that the morbid process was again advancing. The wound showed no disposition to heal, and the surrounding tissues were rapidly infiltrated.

On May 1, as a last resort, it was decided to try the *x*-ray. It was really a forlorn hope, for it seemed almost impossible to favorably affect a mass which was now hard and extended to great depth. The gaping wound was two inches deep, covered with sluggish granulations, and the sides infiltrated, involving almost the entire neck on that side.

Considering the gravity of the case, it was decided to push the treatment, even at the risk of causing some painful reaction, the danger of a burn having been fully explained to the patient.

The current was generated by a static electric machine. The tube was a "Gold Medal," No. 3572. It was high most of the time. At first the tube was placed at six inches from the patient, but later it was brought as near as three inches. The shoulder and face were protected by a lead mask. The first seance was ten minutes, but the time was increased to twenty, and later, thirty minutes. A few applications were made on alternate days, and after that were given daily. Occasionally the reaction was uncomfortably severe, and the treatment had to be suspended for a few days. At no time was there anything approaching a burn, nor was there any serious discomfort.

---

* Read before the Mississippi Valley Medical Association, October, 1902.

No black spots appeared after the first exposure, and after the third there was apparent improvement, and the skin had entirely cicatrized in two weeks. The infiltration gradually faded away. The last place to be affected was just behind the angle of the jaw. It occurred to me that the bone might be protecting it. The position was so changed as to allow the rays to come from behind, after which the place soon softened and disappeared.

By the last of July there was no evidence of the disease except the cicatrix. The applications were made once a week for another month, and now we have him report once a month. The growth never occasioned severe pain, but there was a drawing, uncomfortable feeling. This disappeared as soon as the treatment was begun, but would always return if it were suspended for a few days.

There was another interesting feature worthy of mention. In adjusting the lead mask, he often steadied it with his hand, so that two fingers were exposed to the ray They became very red and shed their nails. This shows that the nutrition of the tissues is profoundly affected by it. The fingers, since guarded from exposure, are regaining their normal condition.

The tumor removed at the operation was hardened and examined by Dr. William R. Davidson, who made the diagnosis of alveolar melanotic sarcoma. A specimen was also sent to Dr. B. F. Cline of the Post-Graduate Medical School of New York, who confirmed the diagnosis.

We have now under treatment a number of cases, some of whom show improvements, but the time is too short to judge of the effects. Two of them have been entirely relieved from pain.

We had considerable trouble with our tubes, five in all; they would become too high when much used. Baking helped them sometimes, but not always.

Phototherapy opens up a very interesting field for investigation, which I will not here discuss, but briefly report a few studies we have made. It does not seem to me that theories can be of any great value while our information is so meager. Let us gather the facts first.

To me the most important question is whether or not the *x*-ray is germicidal in its action. The parasitic origin of cancer is not established, although the evidence lends some probability to it, and whether it is or not, the effect of the ray on germ life comes up in its application to a wide range of diseases. If we could kill germs in tissue without destroying it we would have a most potent remedy.

In conjunction with my associates, Drs. James Welborn and Leartus Owen, the following experiments were made:

EFFECTS OF X-RAYS ON BOUILLON CULTURES OF PYOGENIC GERMS IN TEST TUBES.

August 9—Three tubes of sterile bouillon marked 1, 2 and 3, inoculated from pus of suppurating wound.

August 10—Culture media turbid. Shows staphylococci and diplococci, with methylene blue.

August 11—Nos. 1 and 2 exposed to *x*-ray. Time, 10 minutes. Distance, 12 inches. Tubes 1′ and 2′ inoculated from Nos. 1 and 2.

August 12—Tubes 1′ and 2′ show growth of organisms. Tubes 1 and 2 exposed for second time to *x*-ray. Time, 10 minutes. Distance, 12 inches. Tubes 1″ and 2″ inoculated from 1 and 2.

August 13—Tubes 1″ and 2″ show growth of organisms. Tubes 1 and 2 exposed 20 minutes to *x*-ray. Tubes 1‴ and 2‴ inoculated from 1 and 2.

August 14—Tubes 1‴ and 2‴ show growth of same organism as the original tubes.

The glass of the tubes seems to obstruct the passage of the rays, giving a dark shadow with the fluoroscope. Hence, we concluded to expose cultures without the intervention of glass.

EXPERIMENTS CONTINUED WITH BOUILLON GELATIN MEDIA IN PETRI DISHES.

August 16—Three plates, 1, 2 and 3, inoculated from pus of carbuncle, showing staphylococci.

August 18—All three plates show extensive growth of the staphylococci and also a fungus.

Plates 1 and 2 exposed to *x*-ray for 30 minutes. Distance, 10 inches. Covers were removed from plates during exposure.

After exposure three culture tubes, 1′, 2′, 3′, were inoculated from plates 1, 2, 3.

August 19—Culture tubes 1′, 2′, 3′ all show cultures of organisms.

EXPERIMENTS WITH RABBITS.

Two rabbits inoculated in each hind leg with pus showing staphylococci and diplococci.

Localized abscess resulted at the site of each inoculation.

Rabbit 1, exposed to *x*-ray for one-half hour.

No change resulted in abscess, but rabbit died on second day.

September 29—Rabbit 2, exposed for one-half hour, the rays being directed on the right leg.

October 1—Rabbit in good condition. Infection the same. Exposed right leg one-half hour.

October 3—Abscesses are much diminished, but not more so in right leg than in left.

In conclusion I would again remind you that all our work in this line is new. Further experience will be required to determine the exact position of the *x*-ray as a curative agent, and the permanency of its effects. It will be very interesting to study the method of its action, and doubtless many improvements will be made.

In the meantime we have much to encourage us, for if only a small proportion of hitherto incurables are rescued by it, we will be well repaid for the trials so far made.

I can not close without the remark that while this treatment is still under investigation we should not forsake previous, well-established principles. Growths should be excised where accessible and all other established means of relief should be employed, and after that the *x*-ray.

But in all cases not amenable to other methods the *x*-ray should be given a trial.

MORPHIN AND COCAIN INTOXICATION.*

GEORGE P. DALE, M.D.

DAYTON, OHIO.

A few years ago I had occasion to observe that the prevalence of the several drug habits, notably morphin and cocain, was on the increase, especially among that class of people found in the charity wards of the public hospitals.

The victim of one or the other of these drugs becomes such after a somewhat different path. Cocainism is more quickly acquired, cases being on record of cocain eaters in Calcutta who have raised their dose from 1 to 12 grains in a month's time. This, while it is exceptional in this country, is frequent in India and other tropical countries, where the habit is very prevalent. The doses may be enormously increased, and 30 to 40 grains a day is not uncommon. The habit is on the increase, the drug often being given by physicians as a cure for morphinism, and is also greatly used for its sustaining virtues in physical exertion.

---

* Read before the Montgomery County Medical Society, Oct. 3, 1902.

Its irritating effects consist of a briskness of perception and removal of fatigue, but are very temporary, and unless the dose is soon renewed are quickly followed by depression. Later insomnia and anorexia are noted, followed by an increase of the temporary prostration, diarrhea, and fits of semi-consciousness may appear, and there is loss of the power of control. Later the face becomes sallow, eyes sunken and there are emaciation, impairment of the eliminating functions and loss of memory. The will becomes weakened to the point of imbecility and the delusion of persecution is often seen.

The morphinomaniac acquires his unenviable state after a longer period of drug taking than the cocain fiend. With his syringe and a case of tablets he is a familiar object possessed of a vice scarcely less than that of alcoholic drunkenness. He begins with feelings of satisfaction and perfect comfort, which continue as long as the drug is taken in sufficient amount. He is known by his disorderliness and is usually a clever and often an interesting person full of schemes which never materialize. There will be gradually weakening of the moral sense, depravity and indecency. As the necessity for increased doses becomes more urgent the disturbances of general health are manifest. He becomes restless, irritable, has disturbed sleep, deranged appetite and digestion; is sallow, emaciated, gray and prematurely aged and even a young person may appear wizened and haggard. He may die cut off by some chance malady, but often from extreme exhaustion. Allbutt says:

> The slavery of coca is worse than that of morphia, it is more destructive of mind and body and harder to put aside. The morphinist still retains some desire to defeat his enemy and is filled with gratitude when the cure is complete. The cocainist is so reduced in intelligence that he neither desires emancipation nor feels any thrill of joy when released. Hence the prognosis in cocainism is worse.

That the changes taking place in the human organism as the result of the constant use of these drugs would be fertile ground for the propagation of criminal ideas can not be doubted. During the past summer I was in communication with a number of superintendents of police and judges of police courts in the large cities in regard to the relation these drug habits bear to the prevalence of crime. Their replies as to the increase of the habits and some of the estimates and statements made are interesting and somewhat startling, and surely indicate that these two drugs have a greater hold on certain classes of people than most of us are aware. Superintendent Muth of Allegheny, Pa., writes:

> In my experience with the criminal classes running through many years, the opium habit furnishes an incentive to more crime than any vice to which unfortunate humanity can be addicted. Also that opium increases crime and is the real cause of at least four-fifths of all the offenses committed.

The fact exists that the majority of people of the criminal class who have been most successful in their work have begun as youths, and they also become addicted to a drug habit early in their career if at all.

Crimes committed under drug intoxication are often such as require cunning, boldness and treachery. He has a courage and will he would not possess were he not under such influence, and he also exhibits a recklessness and "don't-care" feeling that carries him deeper in his work than if his mind were normal. This may cause him to commit grave offenses, but it is usually the smaller crimes, as larceny, assault and battery, etc., that are committed under drug influence. Often small thefts are done, not for the sake of the theft itself, but for the purpose of obtaining money to buy more "dope."

The association of drug habits with chronic alcoholism varies. Probably more often than not they coexist, but cases are frequent where after the drug habit is established the taking of alcoholics is discontinued. The victim often begins taking a drug by putting it in beer or whisky. One judge says: "One hundred per cent. more crimes are committed by cocain fiends than by persons who are addicted to the alcoholic habit." Quoting again from Superintendent Muth, he says:

> I am aware that some writers on crime and its causes attribute the criminal impulse to "alcoholic drinks," to ignorance and to hereditary tendencies. While all these are the causes of many shocking crimes, yet, if complete statistics were gathered they would undoubtedly show that the opium habit is the greatest incentive in the commission of crimes that require cunning, boldness and treachery. In nine cases out of ten the shoplifters are slaves to this habit, and it is only while under the influence of the drug that they can do any skillful work.

We see often cases of drug habit among the well-to-do and wealthy classes, but it is among the lower classes, and especially the prostitute, where it is, I might say, epidemic. It is the negro and the lower class of white prostitutes who take these drugs as a steady diet, and it is estimated that 80 per cent. of these people use morphin or cocain in some form or other.

In a recent article in the *Medical Record,* Perry speaks of the degeneration of the southern negro, assigning as causes the venereal diseases, tuberculosis and insanity. This latter, he says, has increased in the last forty years twenty fold, while the negro population has little more than doubled. This, he believes, is only a small part hereditary insanity, but is due to a removal of the healthy country life and congregation in cities, and in conclusion he gives the drug habits due credit for their work, and says they are greatly on the increase.

Where and how easily are these drugs obtained? In almost every city that cunning, slick individual, the Chinese, operates his opium den, and those who desire a smoke can find ample opportunity, and opium outfits are also frequently found in houses of ill-fame, where if one inmate smokes they all do. The ease with which morphin and cocain can be purchased from the druggist without a physician's prescription is appalling. Some druggists in the "tenderloin districts" rely largely on these sales to keep up their volume of business, and some have even said they could not exist if it were not for the sale of cocain. They keep it put up in 10 and 25 cent packages, and all the user has to do is to ask for 10 cents worth of "coke" and he gets it, and the all-night stores in these districts do a flourishing business in this commodity. The sales of morphin and cocain in small quantities has been very much on the increase the past three years, and those who once become users will, in the majority of cases, continue, and the number who use them constantly is daily increasing. Usually these sales are not even registered, as is required in many states when poisons are sold, but are dispensed as any nonpoisonous drug. I can not give the druggist all the censure, but some physicians and many quacks must take due credit for hasty or thoughtless dispensing or prescribing.

That existing laws are not enforced is undoubtedly true, but it is also true that many existing laws on this subject are not sufficiently broad. A recent enactment as to the sale of cocain in Iowa provides:

> No one, by himself, clerk, employe or agent, shall either directly or indirectly sell or give away any cocain or preparation containing cocain except on the written prescription of a registered physician for medical purposes. And no such prescription shall be refilled except on the written order of a physician.

It is this latter clause as to the refilling of a prescription that gives to the physician and the physician only the entire control.

I bring these few facts to your attention, not because of the facts themselves, but with the hope that before long there will be some united effort of the medical profession to control the indiscriminate sale of those drugs that are so antagonistic to the physical welfare of humanity.

1224 W. Third Street.

A NOTE ON THE VALUE OF AUSCULTATORY-RESONANCE AND AUSCULTATORY-PERCUSSION AS AIDS IN DIAGNOSIS.

CARL C. WARDEN, Ph.B., M.D.

BATTLE CREEK, MICH.

The purpose of this note is to bring more generally before the profession the art of auscultatory-percussion and auscultatory-resonance. Auscultation and percussion, together with palpation and inspection, have long been the foundations of diagnostic structure, but even with foundations laid we frequently build no higher than the first story because of inaccuracies of interpretation or for the reason that the draught of our plans misleads us. To be able accurately to map out the normal viscera of the body on its surface is a great achievement, but under pathologic conditions the task becomes more difficult and one is not infrequently baffled outright in the attempt. An opportunity to observe the remarkable results to be obtained by a combination of auscultation and percussion was recently afforded in the clinic of Dr. S. H. Habershon, physician to the out-patient department of the Brompton Hospital for Diseases of the Chest, London. Dr. Habershon has made use of the methods for a considerable time to great advantage, and he is entitled to the credit of bringing them to the high degree of perfection they have now attained. Personal experience with the methods has thoroughly convinced me of their value, and it affords me pleasure to commend them to the profession and to place credit to the tireless worker who has developed them.

Auscultatory-resonance was evolved from auscultatory-percussion, and the latter term is sometimes loosely applied to it. It is assumed that diagnosticians generally are familiar with the method of auscultatory-percussion, which consists in placing the stethoscope over the area of the viscus to be outlined and percussing lightly with the finger tip in converging lines toward its margins. Each organ gives forth, as soon as the percussing finger reaches its limits, a tone that is characteristic and of the same quality all over the surface area of the organ, depending in quality and intensity on the size and density of the organ.

If, now, one substitutes for the percussing finger a vibrating tuning fork it will be observed that a musical tone is transmitted to the ear through the stethoscope. This tone varies in intensity, quality and character with the size and density of the subjacent organ. If a stethoscope be placed over the area of the liver on the anterior wall of the thorax and the stem of a vibrating fork be placed lightly on the skin in the same area, there will be heard a note of definite quality that remains the same so long as the fork does not progress beyond the liver borders, but which diminishes slightly in intensity the further it is moved from the bell of the stethoscope. When the fork is moved beyond the liver margin, up or down, the tone suddenly changes entirely in quality and intensity. So with every viscus. Each organ transmits a characteristic tone of a definite quality and intensity, depending on the form, size and density of that organ. A musical ear is not essential, though it must be confessed that one so gifted will be able to appreciate finer gradations of tone.

LUNGS.

To apply the method, for purposes of illustration, to the outlining and examination of the lungs, let us proceed as follows: Select a tuning fork having a handle conveniently long and that is pitched to C or A, preferably the latter (435 vibrations). Place the bell of the stethoscope over the right lung anteriorly, as at O in Figure 1, set the fork in vibration and rest the handle lightly but firmly on the skin outside the lung area and progress rapidly, with short intervals, in a straight line toward O. When the margin of the lung is reached the musical tone that reaches the ear is heard suddenly to alter in quality and intensity, and from a muffled, distant character, it becomes resonant, clear and close to the ear. At whatever point the line of the advancing fork crosses lung margin the same characteristic tone is heard. With these manipulations the pressure of stethoscope and fork should be uniform, or as nearly so as possible, avoiding firm pressure one moment and light pressure the next. In this manner the boundaries of the lung may be made out and outlined with pencil on the skin. As the fork approaches the lung across the liver area the lung tone will become apparent so soon as the lowest margin is reached, modified slightly in intensity owing to dense liver beneath, but true in quality.

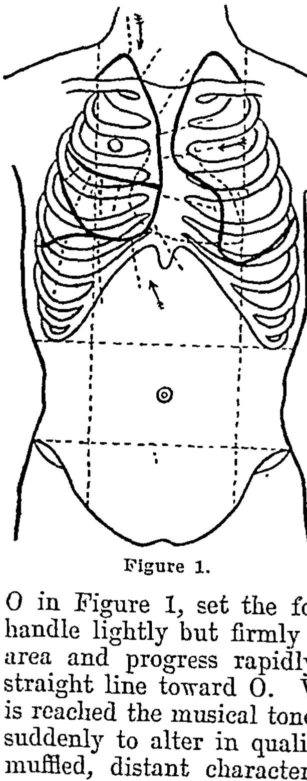

Figure 1.

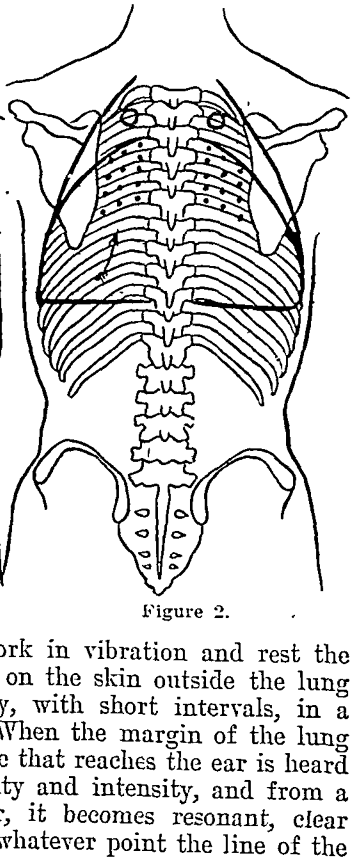

Figure 2.

If the stethoscope be held at O it will be possible accurately to outline the cleft between upper and middle lobes of the lung by proceeding in a manner similar to that detailed above, shown also in Figure 1. The lung as a whole has a definite, characteristic resonance and each lobe has also a tone of its own depending on the difference in size between them. The line of demarkation between the lobes is to be made out equally well at the back, Figure 2. The borders of the left lung may be sketched in the same manner, and it is interesting to observe how well one may map out the portion excavated for the heart. If a portion of lung is consolidated or contains a cavity the affected area will give an altered note, a consolidated lobe yielding a tone similar to that of the liver, while a cavity gives forth a peculiar loud resonance, close to the ear, corresponding to the "amphoric" breath sound. Pleural effusions and mediastinal growths may be made out with great precision.

The loudness of tone heard when stethoscope and fork are placed over the same rib or over the sternum may sometimes lead one into error, but practice will diminish the chances of going astray. It is to be remembered that to obtain best results the stethoscope always should be placed over the viscus to be outlined and the fork brought toward it; unwise is it to attempt to outline by progressing away from an organ or to determine on the margin of a contiguous organ in such manner. Take each viscus separately.

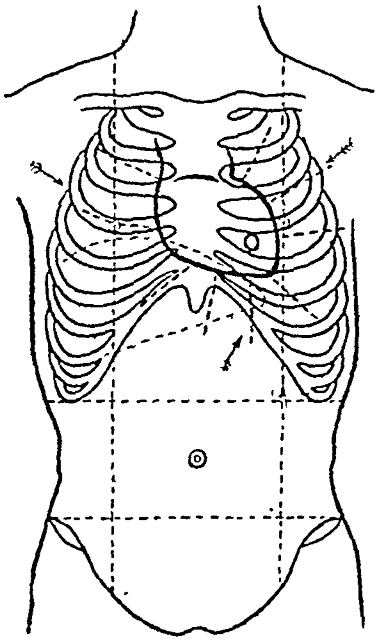

Figure 3.

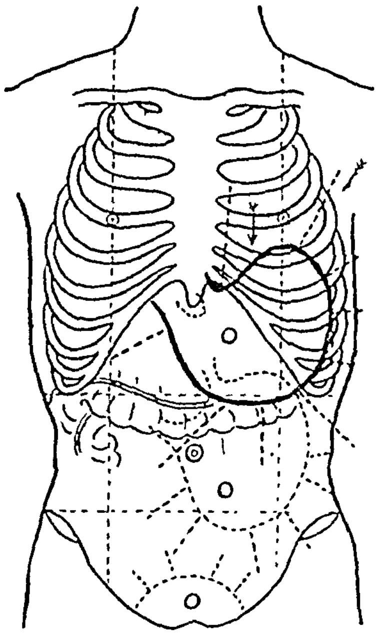

Figure 4.

HEART.

To outline the heart we proceed in practically the same manner; the apex beat is located, the stethoscope placed over any convenient portion of the heart area and vibrating fork made to approach in converging, stellar lines, Figure 3. It will become apparent that the line of separation between liver and heart is very well marked, determinable without difficulty and may be verified later by outlining the liver. It is affirmed that in some instances it is possible to make out the septum of the heart by this method, but the writer has succeeded, as he thought, in one instance only, where there existed a marked concentric hypertrophy. Where dulness in the fifth right intercostal space, parasternal line, points to fluid in the pericardium and where the triangular area of precordial dulness indicates effusion, this method is of great value in determining definitely thereon, since by means of it we are able accurately to map out the dulness and check over the results of ordinary percussion. It also is available in those cases of aneurism "with symptoms," aneurisms of the second portion of the aorta which are often difficult to make out.

LIVER.

Auscultatory-resonance and auscultatory-percussion are very valuable in determining the outlines of the liver, Figure 5. Given a case where the lower liver dulness is obliterated because of a peritoneal cavity distended with gas. Percuss downward over the thorax in the usual manner until dulness is reached, place the stethoscope over the dull area and proceed as indicated in the figure.

In several instances one has been able to verify findings at autopsy where during life the border could be made out by no other means. When enlargements of the gall bladder exist they become apparent often when conditions do not permit of their discovery otherwise. No matter how obese the patient the method is applicable. Only recently the spleen was accurately outlined in a patient weighing 230 pounds in whom it was impossible either to palpate the organ or to elicit dulness by ordinary percussion. Generally speaking the outlines obtained by auscultatory-resonance coincide nearly with the areas of deep dulness.

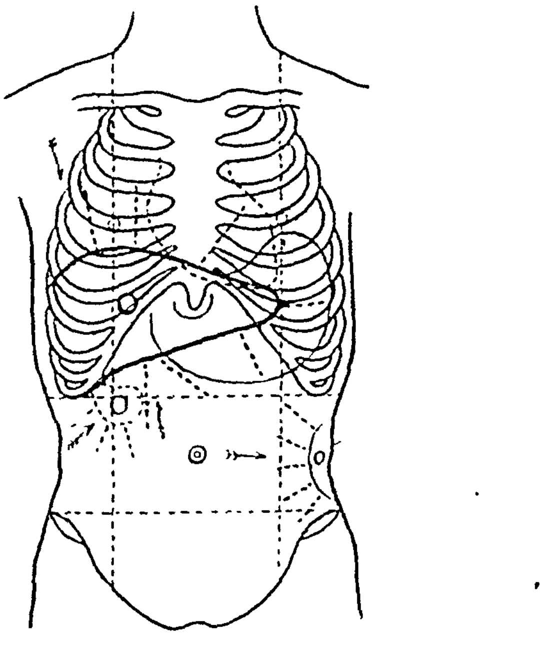

Figure 5.

STOMACH.

With regard to the stomach, it may be said that the methods already described will settle many perplexing points. The stomach gives out resonance peculiar to itself, contrasting sharply with the tones of heart, liver, spleen and colon. When the stomach is of normal size and in normal position the greater curvature may be outlined readily (Fig. 4), but when the organ is dilated or prolapsed or when these conditions coexist the method serves to best advantage. I have been able to verify results in such cases by dilating the stomach with air and by the use of the diaphane, when it became apparent that the slight deviations from the contours already traced were the result, not of error in the method, but rather of further displacement of the organ by the air or water introduced. The method has availed frequently in post-operative cases where there existed a suspicion of a full and dilated stomach, a condition to be dreaded, and one has been able to distinguish between such a status and a dilated colon. It is such cases that require nice decisions on the part of the physician since so much depends on proper therapeutic measures.

OTHER USES.

The existence of small amounts of intraperitoneal effusion may be demonstrated, as shown in Figure 5.

Areas of fibrinous exudate in the abdomen, tumors, distended bladder. pericecal inflammatory masses, aneurisms and splenic enlargements yield their outlines to auscultatory-resonance. Of its value in the topography of the kidneys I have not had opportunity to convince myself. Each method of precision has its limitations, but by a systematic use of all of them we may arrive at conclusions. Auscultatory-resonance or percussion is not intended to supplant any of the older methods. It should be used to check over results obtained by ordinary procedure and as an extra aid in the unravelling of knotty skeins of evidence.

A conscientious investigation of their merits will convince one that their practice is not esoteric, not a fad, but a legitimate and valuable aid to diagnosis.

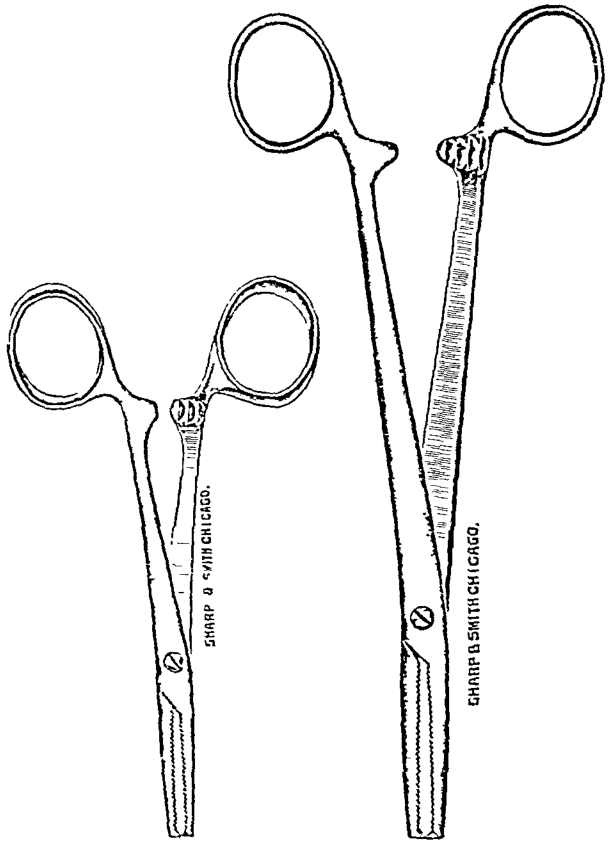
New Instruments.

A NEW HEMOSTATIC FORCEPS.

WELLER VAN HOOK, M.D.

CHICAGO.

It is rare to find a hemostatic forceps, as supplied in the ordinary instrument shops, which will last through more than a dozen ordinary operations without extensive repair. The selection of the proper instrument is frequently impossible because most of the instrument dealers carry in stock only the poorest constructed instruments, made by large factories in Germany. The models selected by these manufacturers are frequently such as have many excellent points, but, owing to failure in some minor particular, the instrument soon deteriorates.



I have had an artery forceps made which seems to combine a number of useful qualities. The forceps are made in two sizes. The dimensions of the smaller size are the following: total length, 5¼ inches; distance from lock to point, 1¾ inches; distance from lock to proximal end, 3½ inches. The dimensions of the larger forceps are: total length, 7¼ inches; distance from lock to point, 2 inches; distance from lock to proximal end, 5¼ inches.

No single new feature is introduced into the design of these forceps, but it is believed that the combination of old points of construction will make these instruments more satisfactory and durable than those commonly found on the market. The forceps are provided with mouse-teethed extremities and serrated jaws. After the plan of Doyen, they are made to meet first at the points, the jaws coming together gradually from before backward as increasing pressure is applied on the handles. Sufficient elasticity of the steel is provided to enable one to get the advantage of this principle. The branches are made sufficiently heavy, so that the shearing strain will not readily wear them out. The catches are unusually deeply grooved, preventing their readily slipping apart. The branches are so set that they lock firmly on the first notch. The rings are beveled, so that one may easily apply the rather firm pressure necessary to close the strong instrument. It will be noted that the length of the jaws in proportion to the length of the handles is short. This serves two purposes: it gives the operator greater leverage; and second, it gives greater strength to this part of the forceps, where so frequently lightness of material and length of jaw cause the forceps to twist and the ends of the instrument to turn over like a crossbill.

A most important point about these forceps is the return to the old-fashioned screw lock. The screw is made especially large to resist the shearing strain. This lock has not only the advantage of being very much firmer, but has the advantage of being adjustable for wear. The writer uses this lock for scissors also for the same reason. The objection that the forceps can not be taken apart for cleaning is trivial, since boiling in sodium carbonate (ordinary sal soda) will remove the materials which usually constitute the dirt.

AN IRRIGATING STAND.

WALTER E. M. RANCHOUS, M.D.

COLUMBUS, OHIO.

The accompanying illustration shows an irrigating stand of use to the venereal specialist and also to the general practitioner who has much to do with the irrigating treatment of gonorrhea in the male. It will enable the physician to get conveniently near his patient and irrigate without soiling the clothes of either party, since there is no splashing of the returning fluid other than that which is the receiving basin will accommodate.

THE JOURNAL OF THE
AMERICAN MEDICAL ASSOCIATION

103 Dearborn Avenue :: :: Chicago, Ill.

Cable Address: "Medic, Chicago"

Subscription price: Five dollars per annum in advance

SATURDAY, MAY 2, 1903.

THE JOURNAL, THE GENERAL PRACTITIONER AND MEDICAL PROGRESS.

From time to time The Journal receives letters from various parts of the country in which the writers point out that in their opinion The Journal "fails to meet the needs of the general practitioner." It has been complained that "the articles are mainly on subjects of interest only to the specialist"; that the papers read at the annual meetings "are way beyond the average man" in certain respects; that those who endeavor to teach the profession by writing articles "obscure their ideas by coining new words" or by using terms not found in dictionaries hardly a year old.

It is not to be understood that these views are those held by even a majority of the readers of The Journal who express themselves in regard to their impressions of its usefulness. These views are, however, heard sufficiently often to merit some notice. They seem to represent the feelings of a certain well-meaning and earnest group of men in the profession whose sincerity can not be doubted and whose wants it must be the aim of every representative medical journal to fulfill according to the best of its ability and resources. We believe, however, that any journal would fail in this undertaking if it did not give prominent and full attention to those parts of the large subject of medicine in which progress is being made. The immediate fruitage of much newly-won knowledge depends in large measure on the widest possible diffusion of that knowledge and of the detailed investigations that have led up to it. Of all existing agencies for the dissemination of results of medical research the large weekly medical journals are the most influential because reaching the largest and most diversified circle of readers at the most frequent intervals. It stands to reason that of the great mass of material thus presented there must be a great deal that seems strange and devoid of direct benefit to the man who is absorbed by the exacting and laborious details of general practice with little leisure for careful thought and study. And there are also in every vocation a certain number of men, fortunately a small number, who really are annoyed by the unrest and uncertainty incident to progress. They prefer the dogmatic style of statement, which makes things so perfectly plain because it is assumed that everything is settled definitely and permanently. This mental attitude is hard to overcome and new truths make little or no impression on that sort of men. It is not intended to say that the dissatisfied readers of The Journal belong to this unfortunate class, the existence of which can not be denied, however. In the early days of bacteriology a great deal was said in protest against the rapid change of views in regard to many diseases, their causes and their treatment, and ridicule was bestowed freely on the germ theory. A good deal of unwillingness to accept freely the general teachings of bacteriology still exists in the minds of many respected practitioners who graduated before the days of the practical use of the microscope and the laboratory. And naturally many of these men are wholly unprepared to give sympathetic and interested hearing to the most recent ideas and theories in regard to the complex problems of immunity and cytotoxic action. And so it must also be in the other departments of medical science. The little modicum of knowledge imparted by the medical college years ago in the case of many, perhaps the majority, did not furnish sufficient basis for intelligent general comprehension of the rapid growth that has been and is taking place in medicine. Physiology as taught to-day would hardly be recognized as physiology by those who listened to a set of lectures or two twenty years ago and then dropped their interest in the subject. Since then physical chemistry, physiologic chemistry and pharmacology have developed. Corresponding changes are taking place in many of the clinical branches. Hence there need be no wonder if much of the material in the columns of the medical journals of to-day seems incomprehensible to some.

This condition of affairs will probably always obtain so long as the practice of the art of medicine is so conducted as to lead one further and further away from the fundamental and underlying sciences. More than ever does the medical practitioner need post-graduate study—medical journals, books, medical societies, and post-graduate courses are some of the sources at which he must seek inspiration to maintain his interest in medical progress. The time is ripe for the establishment by our best medical schools and universities of courses for graduates. Medical men must remember that certain truths in medicine as well as elsewhere have in them great powers for growth and fruitfulness, and that the growth must be watched closely lest one fails to recognize its effects and broadening significance. Furthermore, that progressive development also must result in such advances in instruction that the medical graduate of to-day starts out with better preparation for the future and with greater advantages than those of us of the past can be said to enjoy. Certainly this is as it should be.

For the reason that the medical journals of the day must aim to be fully abreast with the advancing waves of progress, words are frequently used that can not be found in "dictionaries hardly a year old" because dictionaries do not regulate the progress of science. As new phenomena are discovered new names become necessary. It is frequently said and with truth that nowadays text-books are antiquated when published, so rapidly does knowledge in many branches accumulate. But when all has been said that there is to say in favor of progress, of development, of the new in medical sciences, the fact remains that simplicity and uniformity of nomenclature are most highly desirable at the same time as it must be acknowledged that they are, from the very nature of things, exceedingly difficult to secure. We believe, too, that the protests against the writers who "obscure their ideas by coining new words" in many cases are fully justified. Medical writers are prone to forget that in medical writing it is ever a golden rule to clothe the ideas in the simplest form, "to say all he has to say in the fewest possible words and the plainest words possible or his readers will misunderstand them." Nothing is gained by the employment of strange words of Greek or Latin derivation when plain English can be used just as well. The constant aim should be to state so clearly what one has to say that there can be no danger, so far as the language used is concerned, of going over the heads of the largest class of the readers of our weekly journals, namely the general practitioner, who most needs the instruction and information it is hoped to convey. Medical as much as any other writers should try more to adapt themselves to the needs of the average reader. It is plain that by so doing they will increase the usefulness of their efforts and the influence of the medical press. When new and strange terms have to be used an explanatory remark might be added that will make their meaning absolutely clear. In our efforts to increase medical knowledge let us not lose sight of the duty to try to make that knowledge easily understood by as many as possible.

THE MICRO-ORGANISM OF SMALLPOX.

Elsewhere in this issue we print a report of the communication made by Professor Councilman to the Boston Society of Medical Sciences, in which he announces that the organism of smallpox has been established definitely to be a protozoan with the various cycles of development peculiar to some of that class of micro-organisms, more particularly the microsporidia. It is not stated by our reporter that the organism has been cultivated outside of the body, and the report does not appear quite clear as to the demonstration of the organisms in the blood of smallpox patients, or of animals experimented on before the appearance of the eruption; consequently, it is not yet possible to form any definite idea as to whether or not the means of diagnosis of smallpox before the appearance of the eruption has been furnished, though Professor Calkin's remarks, as published, suggest this.

The manner of entrance of the organism into the body, the route or routes by which it is carried to the local but disseminated lesions of the skin elsewhere and the various stages of development that it passes through during this complicated process remain to be explained. It is to be remembered that the conclusion of Professor Councilman that the cause of smallpox and vaccinia is a microsporidium is in accord with the interpretations of other and earlier observers of certain interesting bodies found within the cells in vaccinia and in the cutaneous lesions of smallpox. From time to time we have referred in these columns to the significance of the so-called Guarniari's bodies that can be studied in the lesions of vaccinia of the rabbit's cornea, and also to Fuchs' recent work on the "Sporidium vaccinale." It will be recalled that Wasielevski demonstrated that the rabbit's cornea could be inoculated successfully with vaccinia from one animal to another through no less than forty-nine generations, and in all the lesions occurred the peculiar intracellular bodies just referred to. He found, further, that when vaccine material was filtered through bacteria-proof filters the characteristic lesions would not develop on inoculation of rabbits' corneæ with the filtrate. From these facts he concluded that most likely the so-called vaccine bodies were the cause of vaccinia.

The results obtained by the Boston investigators seem to extend and confirm the conclusions of Wasielevski and others, and we trust that the announcement just made means that a decided step forward has been made in the study of smallpox. The complete publication of the work carried on in Boston during the last two or three years will be awaited with interest, and any attempt at critical consideration of the conclusions drawn by Professor Councilman and his coadjutors necessarily must be based on a thorough study of their report.

INTRACELLULAR TOXINS AND THEIR RELATION TO IMMUNITY.

During recent years workers in bacteriology have been largely occupied with the study of the soluble products of bacteria and with their action on the animal body. In view of the brilliant results which followed the discovery and investigation of the soluble toxins of the tetanus and diphtheria bacilli, it was natural to seek similar poisons in connection with the other pathogenic bacteria with the hope of also obtaining specific antitoxic agents to combat them. However, it soon became apparent that many bacteria did not exert their injurious effects through the agency of soluble toxins, and efforts to obtain curative sera by injections of fluid cultures have met with complete failure in the case of most pathogenic bacteria.

More recently the bacterial cell has again claimed more attention, and when the required technic shall have been worked out, it is not too much to hope that results of great importance will be arrived at. Vaughan[1] and his pupils have already contributed valuable results in studies of bacterial cells, and Vaughan has devised some very useful technical methods. They have found the dead cells of each of the pathogenic and non-pathogenic bacteria studied to be poisonous to rabbits and guinea-pigs. The intracellular toxin of a non-pathogenic germ may be even more potent than that of a highly infectious one. Vaughan concludes that the intensity of the infectious properties of a micro-organism is not always measured by the potency of its toxin, but rather depends on the conditions for its growth in the animal body being favorable. He does not think that the intracellular toxins exist as such in the cells, but are atomic groups or side chains of the complex molecule. They can be detached from the cell substance only by the action of agents which break up the complex molecule.

---

[1] Trans. of the Assoc. of Amer. Phys., 1902, xvii, 243.

Macfadyen and Rowland,[2] in the Jenner Institute of Preventive Medicine, London, have been making some very interesting studies of the biologic properties of the intracellular constituents of the typhoid bacillus. They have elaborated a very ingenious technic for obtaining a "typhoid plasma" from typhoid bacilli as near like the living fluid of typhoid bacilli as possible. The bacteria are obtained in a pure state, and rendered brittle at the temperature of liquid air, when they are triturated without the addition of any foreign substance and the fluid contents of the cells allowed to escape. If such intracellular juices of the typhoid bacillus are injected into the monkey, a serum is obtained which possesses both antibacterial and antitoxic properties. Such a serum is curative and preventive as regards the typhoid bacillus and also the intracellular toxin present in the same organism. If these results are confirmed, it will be most important to know whether the intracellular juices of other bacteria, especially of those which do not produce soluble toxins, will give rise to bactericidal and antitoxic substances when injected into suitable animals.

EDUCATION AGAINST TUBERCULOSIS.

The methods adopted by the Phipps Institute for Tuberculosis in Philadelphia deserve the attention of those who are interested in the treatment of poor consumptives and in the prevention of the spread of tuberculosis in our large cities. It is needless to say this work represents one of the most humanitarian purposes that a philanthropist could set before him and merits emulation on the part of those who are in a position to lessen human suffering by direct means. The Phipps Institute methods are not claimed to be original, though they contain some very practical original suggestions. On the contrary, one of the great merits of the system employed is the conservative eclecticism that characterizes it. The most famous institutions for the treatment of tuberculosis, in this country and abroad, have been visited or studied, with the idea of selecting what appeared most commendable in their various characteristic features.

The treatment of the patients is practically limited to the application of the principle that abundant fresh air and a plentiful supply of nutritious food represent the essentials of rational therapy for tuberculosis. If these can be secured, drugs may be almost entirely dispensed with. It is frankly recognized that for poor tuberculosis patients an abundance of nutritious food is not always easy to secure. Part of the income of the large fund provided by the generosity of Mr. Phipps is applied, then, to the provision of the most highly nutritious food easily available and that does not require much care in its preparation. Consumptives who declare that they are too poor to pay for proper food are given daily twelve eggs and three quarts of milk. These are delivered at their residences. The amount of milk is later increased to five quarts, if the patient is able to take that amount with benefit. The usual advice is to take the eggs as nearly raw as possible. Beside the dozen of eggs and three quarts of milk, one full meat meal is insisted on as a necessary part of the daily diet.

With regard to fresh air, patients are advised that the coldest outdoor air is not likely to prove injurious, and that there is more danger for those associated with him in a closed warm room than in a cold open one. The windows of sleeping apartments are to be left constantly open in all weather. If arrangements can be made to that effect, the patient is advised to spend six to eight hours per day reclining in a steamer chair on the roof of his dwelling house, or, if this is not possible, on a porch or in a bay window with the windows open.

Such directions are more suitable to Philadelphia, where many people live in their own houses, than to cities where apartment houses are more frequent. In a word, the regulations in force in sanitariums for the treatment of tuberculosis in this country and in Europe are modified to suit the patients' environment. Consumptives are warned of the danger of going into crowds and against riding in crowded cars, where they may acquire secondary infections.

At each visit to the dispensary, patients are warned with regard to the dangers of spreading tuberculosis, are questioned as to their habits, and are drilled in the taking of precautions that lessen the risks of infection for others. It is always made clear to them that the taking of such precautions is also helpful to themselves, by avoiding the possibility of personal reinfection. The care of the sputum is especially insisted on and minute directions with regard to its disposal frequently repeated. Patients are warned that their clothing may readily carry quantities of tubercle bacilli, and they are shown the necessity for scrupulous cleanliness. The clothes of tuberculosis patients are gathered at suitable intervals and thoroughly sterilized.

It would seem that practically all of the important problems in the prevention of the spread of tuberculosis in large cities are thus deliberately faced and at least an attempt at their solution made.

The educative influence of such an institution on the masses can scarcely be exaggerated. From the very beginning the important lesson is taught that not drugs but fresh air and food are the remedies for tuberculosis. This feature promises to do more to lessen the nostrum evil, with its unfortunate sequelæ, especially in tuberculosis, than any other remedial measure that has been suggested. Well-directed charity and rational instruction seem to vie with each other for first place in the methods thus introduced. We shall hope to hear of great benefit secured by the very practical system thus initiated.

---

[2] Brit. Med. Jour., March 28, 1903, 757.

THE PREVENTION OF RABIES.

It is said that in the last ten years 91 persons have died from hydrophobia in Chicago. Many other parts of the United States appear to have been afflicted with this disease quite as extensively, and there is no indication that in the last decade rabies has become any less frequent in the country at large. It must be confessed that the horror in which this disease is held by the popular imagination is probably fully warranted by all that is known of its clinical manifestations. We fancy there are few ways of leaving this world that one would choose less willingly than an attack of hydrophobia.

There is unqestionably less excuse for the continued existence of this disease in the heart of our crowded American cities than for that of many other forms of infectious disease. It is well known that the simple enforcement of existing regulations regarding the muzzling of dogs would be sufficient to stamp out the infection in all the denser centers of population. The remarkable experience of Great Britain in the matter of dog-muzzling is often referred to, but, in view of existing conditions, it can not be given too great or too frequent publicity. The official reports of Great Britain show the following relation between cases of rabies and the enforcement of muzzling:

YEAR.	CASES.
1887	217
1888	160
1889	312

The alarm caused by this increase led to the adoption of muzzling, with the following result:

YEAR.	CASES.
1890	129
1891	79
1892	38

The muzzling ordinance was then relaxed owing to misguided opposition, with the result of increasing the number of cases:

YEAR.	CASES.
1893	93
1894	248
1895	672

This rapid increase caused a revulsion of feeling and brought about a reversion to the former restriction:

YEAR.	CASES.
1896	438
1897	151
1898	17
1899	9
1900	0

An experiment so frequently repeated and confirmed possesses convincing weight and deserves to be taken into serious consideration by all municipalities in which a dog-muzzling ordinance now exists, but has been allowed to lapse into desuetude. It is worthy of note that the argument embodied in the statistics just quoted has been deemed cogent even in England where, as is well known, the sentimentality of antivivisectionists and other philozoists has in the past proved powerful enough to cripple scientific research and interfere in other ways with the real welfare of both man and the lower animals. Since it is plain that enforced muzzling will speedily eradicate hydrophobia from any given locality, there seems to be good ground for urging the general adoption and persistent enforcement of this measure. This should be urged in season and out of season by those interested in safeguarding the public welfare.

At a recent meeting of the Chicago Medical Society, where this question was discussed, one of the speakers expressed skepticism regarding the value of the Pasteur method of treatment of hydrophobia. It is not clear on what grounds this incredulity is based, since the evidence in favor of the beneficial results achieved by this treatment is almost, if not quite, as massive as that in favor of the antitoxin treatment of diphtheria. The statistics given out by the authorities of the Pasteur Institute at Paris for a series of sixteen years, from 1886 to 1901, show that out of 25,986 persons treated during this period there were only 112 deaths, or a mortality of 0.43 per cent. A large proportion of these persons had been bitten either (1) by an animal demonstrated by subsequent experimental inoculation to have been rabid, or (2) by one pronounced rabid by a competent veterinarian. The last annual report published by the Pasteur Institute[1] shows that in 1901 there were treated 171 persons belonging to the first category and 785 to the second, all others for that year numbering 362. The total number of deaths for this year was only 5. No deaths occurred among persons in the first category, and but four among those in the second, a total mortality percentage for these two groups of 0.42.

A conservative estimate of the proportion of persons who are bitten by rabid dogs who subsequently die with symptoms of hydrophobia places the number at 16 per cent., and in some series that have been reported a much higher percentage than this is recorded. The difference, therefore, is overwhelmingly on the side of the Pasteur method of treatment, and the figures obtained at the Paris Institute have been fully substantiated by the experience of the scores of similar institutes that have been established in various parts of the world.

WAITING-ROOM LITERATURE.

In one of his recent fables, George Ade quotes an old physician, who advises a young man not to take up the profession of medicine. Among other evidences of the unprofitableness of the study, the physician remarks that "we are most of us held down so close to the carpet that we have to buy last year's magazines to put in the waiting room." Mr. Ade is certainly an observer and has probably frequented physicians' waiting rooms not a little to make such a generalization as this. There are many of these rooms where the literature left to pass the patient's time is not only antiquated, but often suggestive of contagion, in view of the handling, etc., by the patients who pass in and out. We have often been a little timid about too close handling of some venerable documents on the waiting room tables of dermatologic specialists, and have sometimes thought it might be better to have none at all for the peace of mind of apprehensive individuals. It is a good thing to have magazines, current illustrated periodicals, etc., on the waiting room table, for the patients would be more likely to patiently await their turn, but there should be either a certificate of disinfection attached to each periodical or the date of publication should show that the matter is moderately new, not lapping too far over in the past century.

---

[1] Annales de l'Institute Pasteur, 1902, 16, p. 452.

THE INTERNATIONAL MADRID CONGRESS.

According to an editorial in *El Siglo Medical* of April 5, the preparations for the International Medical Congress were in a very unsatisfactory condition even at that late date, and it feared that much would be found open to criticism at the time of the meeting. Apparently there has been a lack of enthusiasm and of active co-operation of the medical profession in both the city of Madrid and the other provinces, and to such an extent as to seriously compromise the success of the congress. Our contemporary also seems to anticipate criticism of some of the local institutions, educational and charitable, by a pretty severe condemnation by itself of their present conditions. It is a fact that these international congresses are a heavy draft on the profession of the country entertaining them, and this point has been specially raised in connection with previous meetings. Spain can hardly be expected to do all that has been done on some former occasions, and allowances should be correspondingly made for some deficiencies that might not be expected elsewhere. We are sorry to say that the fears of the editor of *El Siglo Medical* are being realized, according to our correspondent in Madrid. He cables that arrangements show lack of systematic organization and that it is almost impossible to get information or co-operation in making report of the scientific work.

THE INDEX MEDICUS.

We are informed on good authority that the "Index Medicus," the first number of which under the new auspices has just appeared, is not receiving its due support, that 251 copies covers the entire subscription list among the profession, both abroad and in this country. That would bring in a return of only $1,255, with an expenditure of about $12,000 per annum. The Carnegie Institution has generously devoted $10,000 per annum to the publication of the index for three years and it was intended to continue this indefinitely, provided sufficient interest is shown in this enterprise, which has in the past redounded so much to the credit of our country. The "Index Medicus" should go to every place where at least an attempt at clinical or research work is being done, to every insane asylum, to every large hospital, to every medical educational institution, and, in our opinion, it is almost an indispensable adjunct to the editorial work of every medical journal worthy of the name. If it can receive subscriptions from each of these sources, it would not only relieve the Carnegie Institution of its expense, but furnish a considerable surplus for its enlargement and increased usefulness. It is not an American publication alone. It should receive equal patronage from every part of the world. It is just as discreditable, if not more so, that its subscription list from abroad is not more than double or treble what it is in this country. No person who is interested in medical literature, no one who is attempting to do original work, can wilfully dispense with the aids it can offer. The fault of much of the work that has been done and is still being done throughout the world, especially in some of the institutions in this country, is that so little is known of what others are doing and, consequently, a great deal of human effort is needlessly wasted. Much sciolistic conceit would be also avoided if this publication, with its preceding series and additional data from the "Index Catalogue," could be properly utilized, and medical literature would be a far more satisfactory thing than it is at present. Brown-Sequard, the celebrated French physiologist, used to bitterly complain of the amount of rediscovery of his work that he was constantly seeing in the German literature. It is only by such bibliographies as the "Index Medicus" that much of this can be avoided. We hope the subscription list will be at least quadrupled. The very moderate subscription price, $5, puts it within the reach of everyone who is attempting to do any medical literary work, and no one should attempt that without having at least access to its aid. We do not believe in multiplication of references or unnecessarily elaborate bibliographies, and the rule of verifying one's references by the originals, of course, is a good one to be followed, but there is no better first guide to medical literature than the "Index Medicus" as now presented to the profession.

Medical News.

CALIFORNIA.

State Board Examination.—At the April examinations for license to practice medicine 39 applicants appeared, 25 of whom passed; 12 were rejected and 2 were conditioned.

New Oakland Health Board.—Drs. J. Hamilton Todd, former health officer; Arthur L. Cunningham and Samuel H. Buteau, Oakland, have been appointed members of the Board of Health.

Typhoid at Stanford.—It is reported that a hundred cases of typhoid fever exist in and about Stanford University, Palo Alto, and that two deaths have occurred. The cause is supposed to be infected milk supplied by a dairy in Palo Alto.

Surgeons Sued.—Mrs. Edna Rooney, Oroville, has sued two homeopathic physicians for $25,000 damages on account of the death of her husband. She alleges bunglesome and negligent attention and a mistake in diagnosis by reason of which her husband's left eye was enucleated for malignant disease, the patient dying a few days later.

Personal.—Dr. Samuel E. Latta, Stockton, has been appointed a member of the San Joaquin Insanity Commission.——Dr. Fred W. Colman has been elected health officer of Lodi, vice Dr. E. A. Burchard, resigned.——Dr. S. W. R. Langdon has been appointed a member of the Stockton Board of Health, succeeding Dr. Charles R. Harry, who is going to Europe for a course of advanced study.——Dr. Ernest B. Hoag has been appointed city bacteriologist of Pasadena.

ILLINOIS.

Chicago.

School Moves.—The Illinois School of Electro-Therapeutics has moved into its new quarters at 35 Randolph street.

Suit for Damages.—Mrs. Martha E. Jacobs has sued Dr. Espy L. Smith for $10,000 damages. She alleges that she has been permanently crippled by reason of improper care of a broken leg.

Mikulicz in Chicago.—Dr. Mikulicz of Breslau is in Chicago this week, the guest of Dr. J. B. Murphy and of the Chicago

Surgical Society. He will attend the session of the American Medical Association at New Orleans next week.

Deaths of the Week.—Pneumonia heads the list of deaths for the week with 163, or more than 25 per cent. of the total mortality. There were 64 deaths from consumption; 38 from heart diseases; 30 each from Bright's disease and violence; 28 from bronchitis; 26 from nervous diseases; 19 from measles; 14 from diphtheria; 11 from scarlet fever; 8 from typhoid fever, and 7 each from whooping cough and influenza.

More Smallpox.—Seventeen cases of smallpox were discovered during the week, one of them being a convalescent, the nature of whose disease was not detected until he was well. The remaining sixteen were removed to the isolation hospital before there had been any serious exposure. Thirteen of the seventeen cases—all adults over 40 years of age—had never been vaccinated at all, and four presented old doubtful scars of vaccination performed in infancy.

Death-Rate Still High.—The total deaths recorded during the week were 639, or only one less than for the previous week and 89 more than for the corresponding week of 1902. The average April death rate since 1893 has been 16 25 per 1,000 per annum —the highest being 20.91 in April, 1893, and the lowest 13.84 in April, 1897. For the first twenty-five days of the present April the rate is 18.74 per 1,000, or 35.4 per cent. higher than the lowest and 10.3 per cent. lower than the previous highest.

Warns Again Against Pneumonia and Influenza.—The health department repeats its warning first given in 1898 regarding the gravity of pneumonia and influenza. It emphasizes the necessity of prompt resort to competent medical attention on the first appearance of symptoms, and the importance of isolation of cases, the instant disinfection and speedy destruction of the discharges from the nose, mouth and throat, and other preventive measures which are enforced by all intelligent physicians in the care of other contagious or infectious diseases.

Object to Test.—Medical students at the University of Chicago have protested against the revival of the supplementary examinations on the work of the first two years by the faculty. They designate the examination as "an unnecessary burden and the survival of an obsolete system of medical instruction" and as "an unjust discrimination." The examination is on the entire work of the first two years. It is supplementary to the regular examinations and is said to entail on the students a vast amount of special preparation, which is useless, as they are compelled to take a third examination in the same subjects when applying for license to practice.

INDIANA.

Smallpox.—During March 873 cases of smallpox were reported, with 28 deaths. In comparison with March of 1902 there was an increase of 30 per cent. in area invaded, of 4 per cent. in number of cases, and of 1,300 per cent. in deaths.

Hospital as Memorial of Wife.—Hon. D. D. Dykeman, Logansport, has announced the gift to the city of a hospital to cost $50,000 in memory of his wife, who died in March. He will also arrange that at his death his entire estate will be available as an endowment for the institution.

Indiana Medical College Commencement.—On April 17, a class of 76 received their diplomas as doctors of medicine from Hon. Addison C. Harris, president of the University of Indianapolis, of which the Medical College of Indiana is the medical department. William Lowe Bryan, president of Indiana University, delivered the address to the class.

March Mortality and Morbidity.—The monthly statistics of the State Board of Health shows there were 2,959 deaths in March, an annual rate of 13.8 per 1,000. In the corresponding month of last year the rate was 14.2. Deaths by important causes were: Pulmonary tuberculosis, 432; typhoid fever, 55; diphtheria, 25; scarlet fever, 11; measles, 7; whooping cough, 24; pneumonia, 402; diarrheal diseases, 21; cerebrospinal meningitis, 18; influenza, 88; puerperal fever, 11; cancer, 92; violence, 120, and smallpox, 38. As compared with the corresponding month of last year an increase appears in influenza and violence. Of the total deaths 438, or over 15.8 per cent. were under one year of age, and 797 or 28.8 per cent. were 65 and over. The order of disease prevalence was as follows: Influenza, smallpox, rheumatism, bronchitis, pneumonia, tonsillitis, scarlet fever, pleuritis, measles, typhoid fever, whooping cough, intermittent fever, erysipelas, diphtheria and croup, diarrhea, inflammation of bowels, puerperal fever, dysentery, cerebrospinal meningitis, cholera infantum and cholera morbus.

IOWA.

Smallpox Near Sanborn.—A case of smallpox in a farmhand near Sanborn is reported by Dr. Leary, who is in attendance. This is the first case in this vicinity for a year.

A Test Case.—Dr. Benjamin A. Stockdale, Council Bluffs, has filed suit against the treasurer of state, to recover $250 paid as a license fee as an itinerant physician. In his petition Dr. Stockdale attacks the constitutionality of the law which discriminates between local and itinerant physicians, and charges that the law violates the state constitution and the fourteenth amendment to the constitution of the United States.

Commencement.—Drake University Medical Department, Des Moines, graduated a class of 11, April 22. Dr. A. Raymond Amos, the new dean of the college, delivered the address of the evening, and Dean Lewis Schooler presented the class to General F. M. Drake, who conferred the degrees.——On April 29 a class of 13 was graduated from Sioux City Medical College. Dr. George W. Beggs, president of the board, conferred the degrees.

Webster City's Hospital.—Mercy Hospital, just completed in Webster City, is the property of the Northwest Iowa Conference of the M. E. church. The structure was built by Jacob M. Funk at a cost of $25,000. and was presented on the condition that patients be admitted regardless of race, color, religion or financial condition. The hospital contains more than 40 rooms and will accommodate ordinarily about 35 patients.

KANSAS.

Diphtheria Near Hartford.—Diphtheria is said to be raging in the southern part of Lyon County. It is said that seven out of nine children in one family on a farm near Hartford have died.

Smallpox, Not Bubonic Plague.—The disease reported from Rice County as bubonic plague has proven to be confluent smallpox. Of the first twelve affected, 8 died. The disease has been confined strictly to three towns, Delavan, in the west end of Morris County, and Geneseo and Bushton in Rice County.

New Doctors.—The eleventh annual commencement of Kansas Medical College, Topeka, was held March 27, when a class of 12 was graduated. Dr. John E. Minney, dean of the faculty, presided, and gave a short sketch of the history of the college; Dr. Plass, president of Washburn University, delivered the address to the class; Dr. O. Portis Davis made the address on behalf of the faculty, and Dr. John C. McClintock, president, conferred the degrees.

Temporary Permits to Practice.—Dr. Henry W. Roby, secretary of the Kansas State Board of Medical Registration and Examination, has notified the holders of temporary permits to practice that there is no charge for the temporary permit; that the regulation fees for a permanent license must accompany each application; that the temporary permit must be recorded promptly with the county clerk; that each day it remains unrecorded he is liable to a fine of $50 to $200, and that until his permit is of record, he has no right to practice or to collect fees.

LOUISIANA.

Quarantine Arrangements Complete.—The quarantine arrangements have been completed and the marine inspectors are at their posts in Cuba, Central and South America. Dr. King Holt, Baton Rouge, has been appointed resident inspector at Havana.

Personal.—Dr. Rolando Kuehn, port surgeon at Bluefields, Nicaragua, for 15 years, through many changes of administration and revolutions, and for a time a resident at the leper colony of Molokai, Sandwich Islands, has returned to America to attend the Association session, and is the guest of Dr. Basilidus Lavigne, New Orleans.

Sleeping Car Disinfection.—The State Board of Health has passed a resolution requiring every sleeping car company operating in Louisiana to thoroughly disinfect each sleeping car after every round trip, under such regulations as the board may prescribe, provided that after personal investigation the quarantine committee finds such methods of disinfection necessary.

Louisiana Keeps Her Own Quarantine.—The State Board of Health has decided not to make its quarantine regulations conform with those of the U. S. Public Health and Marine-Hospital Service, or to use the marine-hospital inspectors instead of its own, or to relieve coastwise vessels of the necessity of inspection on entering New Orleans. These changes were suggested by Dr. Lindsley of Havana. The Louisiana board will maintain its own inspectors at all gulf forts where there is considered to be any danger of the importation of disease.

MARYLAND.

Baltimore.

Commencement.—Baltimore University School of Medicine graduated a class of 24, April 21, two of whom were women.

The Crim Sale.—The first three days of the sale of the collection of antiques of the late Dr. Wm. H. Crim terminated on Friday, the receipts being $29,300.

Personal.—Dr. Ira Remsen, president of Johns Hopkins University, was elected vice-president, and Dr. William H. Welch member of council of the National Academy of Services at Washington on April 22.

Fluctuating Mortality.—The fluctuations in the mortality of Baltimore were rather striking. Last week the number of deaths fell to 170, an annual rate of 16 per 1,000, pneumonia and consumption leading with 26 and 22 deaths respectively. One case of smallpox was reported, one of the suspects from Homburgville camp mentioned below.

Control of Tuberculosis.—At a meeting held April 24, for the discussion of measures for the control of tuberculosis, Dr. Herman M. Biggs of the New York Health Department delivered an address on the methods of dealing with the disease in that city. Remarks were also made by Drs. Welch, Osler, Fulton, Thayer, and Health Commissioner Bosley.

Negligence Charged.—Dr. Bosley, health commissioner, charges the health officers of Baltimore County with negligence in not maintaining a strict quarantine at the Homburgville camp near the city where several cases of smallpox have occurred. It is believed that 30 suspects from that camp have been allowed to come to the city. Ten patients have been taken from this camp to the City Quarantine Hospital.

Woman Takes Prize.—Dr. Florence R. Sabin, Denver, Colo., assistant in anatomy in the Johns Hopkins University Medical School, has been awarded the prize of $1,000 offered two years ago by the Naples Table Association for the best thesis of individual research in biology, physics, zoology and chemistry. The award was made by the association at a meeting held at Smith College, April 18. There were 11 candidates for the prize. The work for which Dr. Sabin received this prize was the discovery last year that the lymphatic system arises from the veins. Dr. Sabin graduated at Johns Hopkins in 1900, and is the first woman to receive an appointment as instructor in the medical department. She was a fellow in anatomy there in 1901.

Index Medicus Redivivus.—Drs. William H. Welch and William Osler gave a dinner at the Maryland Club, April 18, to Dr. Robert Fletcher of Washington, editor of the "Index Medicus," to celebrate the revival of its publication. After being published for 21 years this work lapsed for want of support. It has now been resumed through the good offices of Mr. Daniel C. Gilman and Dr. S. Weir Mitchell, who have secured an appropriation for it from the Carnegie Institute of $10,000 per annum for three years. It is understood that the continuation of this amount will depend on the interest taken in the work by the profession. Among those present were Drs. Abraham Jacobi, James R. Chadwick, W. W. Keen, F. P. Henry, Garrison, King and Yarrow of Washington; Acting Surgeon-General De Witt, and Major Kean of the Army, Mr. Marcus Baker of the Carnegie Institute, and others.

MASSACHUSETTS.

Bequests.—Mrs. Phebe R. Sturtivant left $10,000 to the New England Baptist Hospital, located on Parker Hill, Roxbury, Mass.——By the will of John J. Day, Quincy, $5,000 is bequeathed to the Quincy Hospital.

Suit for Autopsy.—A suit for $2,000, brought against the Massachusetts General Hospital for performing an autopsy on a Hebrew, in which the defense claimed that permission was granted, and the plaintiffs declared that by reason of the autopsy certain religious rites were rendered impossible, was decided in favor of the defendant.

First-Aid Training.—At the annual meeting of the Massachusetts Emergency and Hygiene Association, Dr. Grace Wolcott reported 241 patients cared for during the year at the Vincent Hospital and 27 attendants trained in the courses of the training school. Courses of lectures have also been given to firemen and policemen on first-aid and ambulance work.

Disease and Death.—During the week ending April 25 242 deaths were reported in Boston, equivalent to an annual deathrate of 21.52 per 1,000. This increase included 34 deaths from pneumonia; 6 from whooping cough; 20 from heart disease, and 9 from violence. There were 20 cases of diphtheria reported, with 3 deaths; 29 of scarlet fever, with 3 deaths; 11 of typhoid fever, 36 of measles, and 21 new cases of tuberculosis were reported, and 26 deaths from that disease.

Massachusetts General Hospital Report.—The annual report of the Massachusetts General Hospital states that $227,373 was expended during the year. Of this $157,744 was expended for free patients, a sum that is mainly met by special funds and free bed subscriptions; 5,199 patients were treated at an average weekly cost of $17.16; 26,662 patients were treated in the out-patient departments and 4,858 in the accident rooms. At the McLean Hospital for the Insane, in Waverley, which is under the same board of directors, $238,000 was spent for 330 cases, an average weekly cost of $25.99 per patient.

MICHIGAN.

Hospital Site Purchased.—A site at the corner of West Huron and College streets has been purchased by the Pontiac Hospital Association. The ladies in control expect to have the hospital completed this season.

Graduating Exercises.—The Michigan College of Medicine and Surgery, Detroit, graduated a class of 14, April 24. Dr. Hal C. Wyman, dean of the faculty, administered the Hippocratic oath and presented the diplomas.

Open Hospital at Laurium.—The new Northern Michigan General Hospital at Laurium was formally opened April 8. Dr. A. J. Ochsner, Chicago, delivered the address of dedication. The hospital will accommodate 100 patients.

Medical Staff Re-elected.—At the annual meeting of the medical staff of the Saginaw General Hospital, the following officers were re-elected: Dr. Sidney I. Small, president; Dr. Bert B. Rowe, vice-president, and Dr. Elmore E. Curtis, secretary.

"Cuban Itch" at Georgetown.—Ignorant or careless of the danger attending the so-called "Cuban itch," the authorities of Georgetown are said to have paid no attention to the disease which is prevalent in that place. The patients have not been quarantined.

MINNESOTA.

State Board Examines.—Out of 23 applicants for license to practice medicine 20 passed the examination of the State Board of Medical Examiners, and were issued licenses.

Personal.—Dr. Charles Lyman Greene of St. Paul has been appointed professor of theory and practice of medicine in the medical department of the State University of Minnesota.

Object Lesson in Vaccination.—Charles Stevens, secretary of the Anti-Vaccination League of Minneapolis, died from smallpox, April 15. He had frequently denounced vaccination as unefficacious and a barbarous practice.

Smallpox.—In the week ended April 13 there were 162 cases of smallpox reported in the state. Benton Township, Beaver County, furnished 30 cases; St. Paul, 12; and Minneapolis, and Elgin Township, Clay County, each 11.

Medical Course Shortened.—The board of regents of the university has decided to institute a six-year academico-medical course, whereby a student may complete both his academic and medical course in six years, instead of in seven years, as at present obtains.

MISSOURI.

Presentation.—Dr. Max C. Starkloff, health commissioner of St. Louis, was presented with a handsome watch and chain by the employes of the health department, April 23.

Change of Control.—On May 1, at the request of the faculty, the Marion-Sims-Beaumont Medical College, St. Louis, passed under the control of the Jesuit Fathers of the St. Louis University. The terms of agreement between the two faculties are that the university shall contribute $125,000 and control the examinations for entrance. This latter condition is to raise the standard of candidates for admission.

Old Physicians Honored.—On April 14 a banquet was given at the Planters' Hotel, St. Louis, by the St. Louis Medical Society in honor of four of its old members, all octogenarians: Drs. William M. McPheeters, aged 87; William Johnston, aged 88; Simon Pollak, aged 89, and John Bates Johnson, aged 86. The last-named was ill and unable to be present. Dr. William M. McPheeters was graduated from the University of Pennsylvania in 1840, and came to St. Louis a year later. He established the first public dispensary west of the Mississippi River, was a professor in St. Louis Medical College until 1861, when he entered the Confederate service as medical director on the staff of General Price. In 1850 he introduced a resolution in the St. Louis Medical Society, which was followed by the organization of the state medical society. He was president of this society in 1852; president of the St. Louis Medical Society in 1856, and vice-president of the American Medical Association in 1869. Dr. William Johnston received his degree in medicine from the Medical Department of Louisville University in 1837, came to St. Louis in 1850; was president of the St. Louis Medical Society in 1866, and is still in active practice. Dr. Simon Pollak, a native of Bohemia, received his medical education at the University of Vienna and was given his degree in 1835. Two years later he came to the United States, and settled in St. Louis in 1845. In 1852 he founded the Missouri School for the Blind, and in 1860 the eye and ear clinic at Mullanphy Hospital, which he still has in charge. During the Civil War he served in the American Sanitary Commission. He has been many times treasurer, and once president of the St. Louis Medical Society. Dr. John Bates Johnson graduated from Berkshire Medical College, Pittsfield, Mass., in 1840. A year later he came to St. Louis; was one of the faculty of Kemper College from 1846 to 1854, when he was elected professor of clinical medicine in St. Louis Medical College. He was one of the founders, and once vice-president of the American Medical Association; one of the founders and an early president of the state society, and was a member of the sanitary commission in the Civil War. Dr. Elisha H. Gregory responded to the sentiment, "The Old Guard"; Dr. Woodson Moss spoke on "The New Organization"; Dr. W. G. Moore on "Honor to Whom Honor Is Due"; Dr. Alonzo R. Kieffer on "The St. Louis Medical Society," and Dr. LeGrand Atwood on "Before the War." The guests of the evening were also called on for speeches and responded. Dr. Robert M. Funkhouser officiated as toastmaster.

NEW YORK.

Hospital Cornerstone Laid.—The cornerstone of the new $140,000 Norwegian Hospital, Brooklyn, was laid with impressive ceremonies April 19.

Personal.—Dr. Charles G. Stockton, Buffalo, has returned from California.——Dr. Willard Parker was knocked down by an automobile, April 23, sustaining a fracture of the left leg and some contusions.

Mikulicz in Buffalo.—Professor von Mikulicz of Breslau was in Buffalo, April 25, the guest of Dr. Harvey R. Gaylord. He gave a clinic to a large number of professional men, and in the evening a complimentary dinner was tendered him by the profession.

Advice for Consumptives.—President Lederle of the New York City Board of Health has sent out all over the city, especially among the crowded tenement house districts, a printed circular, giving advice on the treatment of consumption, in English, German, French and Hebrew, and calling attention to the fact that the spread of the disease is largely due to spitting.

Milk Adulteration and Proposed Legislation.—The Commissioner of Health states that there has been smuggled into a bill now before the legislature, and known as Senate Bill No. 1104, an apparently innocent clause which, if allowed to become law, will practically nullify the present law under which dealers are prosecuted for the adulteration of milk. The objectionable clause is in connection with the recovery of penalties for violation of the Sanitary Code, and says: "Which shall not be punishable as misdemeanors unless the wilful intent to violate such section shall be first proven." Last year there were collected in fines from milk dealers $19,118, as against $6,292 in 1901. Of 3,970 samples of milk taken for analysis last year 2,095, or 52 per cent., were found to be adulterated.

PENNSYLVANIA.

Telephone Advice.—The Allegheny County Medical Society has adopted a scale of charges of from $2 to $5 for advice given over the telephone.

Ray Bill Defeated.—The Ray bill, the object of which was to raise the standard of preliminary education requisite to entrance to medical colleges, has been defeated in the senate. Its defeat is ascribed to the influence of low-standard medical colleges.

Rabies Is Reported.—Twelve children, playing on the street, were bitten by a mad dog, which ran into a crowd. The victims were all promptly taken to the Pasteur Institute at Allegheny. Two children were also recently taken to the institute from Waynesburg for a similar reason.

Cocain Bill Passed.—This bill was passed by the legislature and has been signed by the governor, fixing a penalty of $100 or six months' imprisonment for the sale of cocain, or any patent or proprietary remedy containing cocain, without a physician's prescription, or to a habitual user of cocain.

Philadelphia Must Pay.—A claim of $67,000 against Philadelphia by the Norristown State Hospital for the Insane for the care of patients sent from the former, was recently allowed by the Supreme Court. The defense was that the city had in previous years overpaid the hospital, but the city's offsets were adjudged to have been barred by the statute of limitations.

Suppression of Smallpox.—For the information of boards of health and of school boards organized as boards of health for the suppression of smallpox, the secretary of the state board has had printed in pamphlet form regulations controlling the disbursement of the $50,000 placed at its disposal to aid in this work. The fund shall not be used for any other purpose than for assisting local communities during the prevalence of smallpox and for meeting just and reasonable expenses incurred in the suppression of that disease. School boards acting as boards of health, applying for aid, must furnish sworn evidence that they have organized formally and have adopted sanitary measures and appointed a paid sanitary agent. In no case will the state board assume the entire expense, and no unvaccinated person shall be appointed to any official position charged with carrying out preventive measures.

Bills Vetoed.—The following bills passed by the legislature were vetoed by the governor: A bill compelling manufacturers of baking powder containing alum to display the words on each package, "this baking powder contains alum." As a reason for veto, the governor states that it would be proper to require that all baking powders should have a label describing the ingredients and their qualities, but that it would be unjust to require one ingredient to be displayed without any reference to quantity. A bill making it unlawful for persons to spit in public conveyances and public places. As a reason for nonapproval of the latter, the governor states that, while spitting is not nice, pleasant or polite, it seems that it would be better to leave the cure of a bad habit to gradual development of a better taste and higher culture rather than to attempt a regulation by law which imposes imprisonment instead of a well-digested health regulation. A bill making it a misdemeanor for persons with a knowledge of a case of contagious disease not to report the fact.

TENNESSEE.

Disinfect After Floods.—The Memphis Board of Health has cleaned and disinfected 163 houses in that part of North Memphis along Bayou Gayoso, which was submerged during the recent floods.

Graduates Class of Forty.—The medical department of Grant University, Chattanooga, held its annual commencement, April 14, graduating a class of 40. Dr. George A. Baxter delivered the faculty address and the degrees were conferred by Rev. G. T. Newcomb.

City Hospital Staff Elected.—On April 20 the following members were elected to the staff of the Memphis City Hospital: Drs. Leon L. Meyer, Alonzo B. Oliver, E. Michel Holder, Maxence B. Herman, William T. Black, James L. Andrews, Oswald S. McCown, William W. Taylor, Elizabeth C. Kane, Pope M. Farrington, Kennedy Jones, George R. Livermore, and B. Frank Turner.

State Board of Medical Examiners.—At the recent examination held in Nashville, 31 out of the 154 applicants for license to practice failed to pass.——The board appointed Dr. Robert Pillow, Columbia, delegate to the Interstate Medical Examiners' Association at New Orleans, May 4, with Dr. William H. Halbert, Nashville, as alternate.——The secretary, Dr. Thomas J. Happel, Trenton, was authorized to make a new directory of the physicians of the state.

UTAH.

Personal.—The Board of Commissioners of the State Mental Hospital has appointed Dr. Daniel H. Calder, Brattleboro, Vt., assistant physician.

Without License.—James Davidson, Salt Lake, has been charged with practicing medicine without a license and a warrant has been issued for his arrest.

State Board Meets.—The State Board of Medical Examiners reorganized at its April meeting and elected Dr. Elias S. Wright, Salt Lake, president; Dr. Robert W. Fisher, Salt Lake, secretary, and Dr. Briant Stringham, Bountiful, treasurer. The board passed 12 out of 13 applicants to practice medicine.

Salt Lake's March Health.—The total mortality for March was 67, representing an annual death rate of 10.72 per 1,000. Pneumonia caused 11 deaths; tuberculosis and cancer each 4, and diphtheria 10. During the month 161 births were reported. Of smallpox 92 new cases were reported; of diphtheria, 37; of scarlet fever, 15; of chicken-pox, 18; of measles, 8, and of typhoid fever, 4.

VERMONT.

To Combat Contagious Disease.—The city council of St. Albans has appointed Dr. Antoine H. Desloges to care for the contagious diseases of the city at an annual salary of $800.

Osteopaths Sued.—John S. Wilkins, Burlington, has sued W. W. Brock and Mrs. L. K. Rosselle of the same city for $10,000 damages, alleging that his wife, who was under treatment by the defendants, died as a result of severe pounding, bruising, etc., administered by them.

Smallpox Scare.—Burlington has a smallpox scare due to the arrival there of a family of nine from Manchester, N. H., whence they eloped. Five of the children and the mother were recovering from smallpox. Starting at night they traveled in a common coach and were found in a crowded tenement in Burlington. Two of the children were at work before the family was traced by the health officers. No one of them can speak English.

WASHINGTON.

Smallpox Under Control.—The county health officer of Walla Walla County reports that smallpox at Wallula, Dixie and College Place is now well under control.

Personal.—Dr. William L. Ludlow, Seattle, recently appointed health officer to succeed Dr. Frank M. Carroll, resigned, has been appointed a member of the local board of medical examiners. ——Dr. A. E. Stuhl, Colfax, has been appointed a member of the State Board of Medical Examiners, vice Dr. William G. Tucker, Port Townsend.

Spokane's Mortality Heavy.—The record for deaths in Spokane was broken in March, in which 84 deaths were reported. Pneumonia caused 10 deaths; tuberculosis, 8; kidney disease, 10; heart disease, 7; and suicide, 5. The prevalence of influenza is considered the cause of the heavy mortality. During the year 520 deaths and 829 births were reported. There were 1,189 cases of contagious disease, smallpox leading with 477.

GENERAL.

Professors Ewald and Tillmanns, of Berlin and Leipsic, respectively, are in this country to attend the session of the American Medical Association at New Orleans next week.

To Watch for Mosquitoes.—The U. S. P. H. and M. H. Service surgeons at the fruit ports of Central and South America have been directed to watch for the *Stegomyia fasciata* and to take precautions to prevent yellow fever and to watch for the occurrence of the disease.

Reception.—The Medical Club of Philadelphia will give a reception at the Hotel Bellevue, May 15, to Dr. George H. Simmons, Chicago, Secretary of the American Medical Association; Prof. von Mikulicz-Radecki, Breslau; Prof. C. A. Ewald, Berlin; Prof. Hans Kehr, Halberstadt, and Prof. Hermann Tillmanns, Leipsic, Germany.

Open Door in Turkey.—American physicians and dentists will now be on the same standing in Turkey as are those of France. They have heretofore been refused examination and could not practice. They will now be allowed to practice if they present good diplomas and pass the examination. This is the result of pressure brought to bear on the sultan by President Roosevelt and U. S. Minister Leishman.

Mikulicz Holds Clinics.—Prof. Johann Mikulicz of Breslau, whose visit to America we mentioned last week, is conducting clinics in various cities, including New York, Cleveland, Philadelphia and Chicago. He expects to visit Denver and other western cities. Dr. Mikulicz speaks very highly of American hospitals and says they far surpass those of Europe. He criticises the administration, however, in that there is not the autocratic power in the hands of one man, which he thinks an advantage in Germany. Here, he says, there is a division of authority and more frequent changes in the personnel of the staff that he thinks do not work out as well. Dr. Mikulicz gave a clinic, April 20, in Bellevue Hospital, for the faculty and students of Cornell University Medical College. He had as cases a gastrostomy, an inguinal hernia and a fibromyoma of the uterus. The gastrostomy was performed according to Witzel's method, which the professor appeared to consider the best. On the hernia he did an ordinary Bassini operation and the other case was treated by myomectomy. The interesting peculiarity of his work was his great dexterity, as the gastrostomy and the hernia were done in an extremely short time. One of the surgeons present remarked that he had never seen a Bassini operation completed more quickly, although the case, to be sure, was of the acquired variety and presented no unusual difficulties. Cotton gloves were also noticeable as the professor's preference. These were changed as fast as they became blood stained, but to the onlooker it seemed that considerable time was wasted in drawing on a clean pair each time. He remarked to the house staff that for appendicitis operations he preferred the old-fashioned transmuscular and not intermuscular incision. In closing the abdominal wound he employed numerous layers of chromicized catgut sutures. This material was also used very freely in suturing the uterus after the myomectomy.

CANADA.

Mandamus Refused.—In the case against the British Columbia physician who was alleged to have attended a woman in confinement while he was intoxicated, the judge has refused to compel the College of Physicians and Surgeons to hear and determine the charges.

McGill University in Need of Funds.—The salaries of McGill professors are the subject of much discussion. Four professors have recently received offers to go elsewhere at largely increased salaries. McGill needs, says one of the professors, a large measure of support from the citizens of Montreal.

A University for British Columbia is proposed by the graduates of the University of Toronto in that province. A large number of those in the terminal city, Vancouver, have met and decided to send a circular to all the graduates throughout the province. The proposal is to have a university with an examining body with power to grant degrees, and without a teaching staff.

Sir James Grant, Ottawa, Honored.—In recognition of fifty years spent in the practice of medicine, during forty-nine of which he was located in Ottawa, Sir James Grant, M.D., was tendered a banquet, April 21, by the medical fraternity of the capital and of the Ottawa valley. Sir James was greatly touched by this expression of friendship, and favored the company with some reminiscences of his medical career.

Personal.—Dr. J. M. Elder, Montreal, has gone to England until July.——Dr. James F. Boyle of Toronto has just completed a post-graduate course in Scotland, where he has succeeded in taking the degrees of L.R.C.P. and L.R.C.S., Edinburgh, and L.F.P.S., Glasgow.——Dr. Casey A. Wood, Chicago, was given the degree of D.C.L., *honoris causa*, at the annual conferring of degrees of Bishop's University, Montreal, April 24.

Dr. J. H. Richardson, Toronto, Honored.—The first medical graduate of the University of Toronto, a teacher of anatomy for half a century, an octogenarian, and one of Toronto's much-respected medical men, was honored by a dinner, April 15, by his old students, at the same time a portrait was presented to the university. A large number of medical men from Toronto, Ontario, and different parts of the United States gathered for the occasion to do honor to their old teacher. Dr. Richardson first began the study of medicine in 1841.

No Dominion Registration.—The Quebec legislature has rejected the proposal to ratify the scheme of Dr. Roddick, M. P., for dominion registration, now known as the Canada Medical Act, 1902. It was defeated by a large majority for the assigned reason of its alleged interference with provincial rights, and the French-Canadian guards very jealously his provincial rights. It is understood that the matter will be brought up again next session, and also before the College of Physicians and Surgeons, which, it will be remembered, voted last fall against the introduction of any legislation into the Quebec house of representatives to make the act operable.

Tuberculosis Conference.—The third annual meeting of the Canadian Association for the Prevention of Tuberculosis was held at Ottawa, April 16. In addressing the conference, Governor-General Minto stated that he believed there were annually not less than 30,000 cases of tuberculosis in Canada and the number of deaths was about 9,000. Dr. H. Beaumont Small read the annual report. In Canada out of 36 hospitals only 13 had special accommodation for consumption patients. Dr. A. J. Richer of Montreal read a paper, in which he estimated the annual loss to Canada from tuberculosis at $72,000,000, this being based on the deaths and invalidation from the disease. He further pointed out that, while the federal government spent nearly $20,000 annually in preventing tuberculosis among cattle, it had only contributed $1,000 towards the same end among human beings.

FOREIGN.

Physician Enters Parliament.—Dr. Charles Frederick Hutchinson has been elected a member of Parliament from Sussex, England. He had retired from active practice.

Women Physicians Graduate at Bonn.—The daughters of two deceased local physicians have recently successfully completed their medical course at Bonn and graduated with distinction, the first women to graduate as physicians there.

Prizes for Essays on Sick Nursing.—Thirty prizes are offered for the best works on the subject: "How to Improve the Patient's Mood and Win His Confidence." The competing articles must be sent in before October 1 to the publishers of the "Deutsche Krankenpflege-Zeitung," Verlag Staude, Berlin W, 35.

Large Fine by the German Court of Honor.—A regularly qualified physician has been fined $375 by the Dresden medical court of honor, the highest fine it is empowered to impose. He was reprimanded officially by the court last September for cooperating with a notorious charlatan, Bilz, and has since resumed his connection with him.

Australian Physician Fined.—Dr. Alfred M. Keighly was fined $250 at Newtown, Australia, March 6, for the alleged representation that he was a legally qualified practitioner. He has given notice of appeal. He asserts that he is a graduate of the Cincinnati College of Medicine and has further studied in Europe. It was said he had been refused registration by the Australian medical board.

Campaign Against Charlatans in Germany.—The German society that has been recently formed for the purpose of educating the public in regard to the evils of quack practices has issued an appeal to the profession at large for funds with which to conduct its work on an extensive scale. All interested are requested to join the society. Subscriptions and other gifts may be sent to the treasurer, Dr. Albert Wilde, Charlottenburg, Rosinenstrasse 3, Germany.

Dangers of Using Circulars for Wrapping Medicines.—A physician at Dresden prescribed a snuff for a patient with asthma, which contained belladonna, hyoscyamus and datura. The druggist dispensed it in two small boxes, each wrapped in a circular advertising somatose. The patient noticed the directions for taking the somatose, a teaspoonful in milk, three times a day. Supposing that they applied to the contents of the boxes, he took a teaspoonful of the snuff in this way, with severe but not fatal intoxication.

Foundation of Monthly for Discussion of Medical Sociology.—A periodical has been founded by M. Fürst and K. Jaffe of Hamburg which announces that it will treat the "borderland" questions of practical medicine and social practice, and all matters pertaining to the material and economic welfare of the profession. organization, etc., without taking part on either side in any movement, merely presenting facts in an objective, scientific way. Subscription $2.50. Publisher, G. Fischer of Jena. The name of the new journal is the "Monatsschrift für soziale Medizin."

Suicide Increases.—The lay press quotes statistics to show that suicide is increasing. In all countries suicide has been more common with men than with women. The proportion of women is greatest in America and Spain. In France during the last twenty-five years the proportion has increased from 157 to 224 per million of the population. In Germany the proportion has been about the same and in Belgium somewhat less. In Russia there was no increase. The increase in other countries was in the following order: Austria, Hungary, Australia, Ireland, Scotland and England.

History of Compulsory Notification of Tuberculosis.—The first edict requiring compulsory notification of phthisis was issued by a king of Spain in 1751. The decree describes the motives for it, and enjoins destruction of the furniture and wearing apparel used by consumptives and replastering the room after a death. Physicians who fail to notify the alcalde of a consumptive patient or the death of a consumptive are fined 200 ducats at the first offense and suspended for one year, and for a second offense 400 ducats and exiled for four years. Nurses, servants and others waiting on the consumptive are required to see that the authorities are notified of the case under penalty of thirty days in prison for the first offense and four years at the galleys for the second. The edict also contains a paragraph directing that dealers in second-hand clothing must keep a record of the persons from whom the clothes are bought and to whom sold.

Organization for Prevention of Spread of Venereal Disease.—Although founded only last October, the German society organized for this purpose already has 1,600 members and has branches in nearly all the large cities of Germany. A similar society has recently been founded at Vienna. The German society held its first congress in March at Frankfurt a. M. The proceedings are to be published in detail in the newly founded "Zeitschrift für die Bekämpfung der Geschlechtskrankheiten," to be issued by the society in addition to its periodical, the "Mitteilungen." The "Zeitschrift" will be in charge of Blaschko, Lesser and A. Neisser, and be published by J. A. Barth of Leipsic; subscription $3. It will contain the more strictly scientific articles on the subject. Some of our exchanges think that the discussions at the March congress will be the starting point for extensive reforms in the prevention of venereal disease. Erb of Heidelberg created something of a sensation by protesting against the assumption that sexual abstinence is always "perfectly harmless," as he has observed isolated cases of neurasthenia and hysteria traceable to this cause in predisposed subjects.

Organization of the Profession in Germany.—Compulsory insurance of wageworkers against sickness has for some years been enforced in Germany. The sick fund societies, or "Krankenkassen," that assume the insurance make contracts with physicians for medical attendance of their members at the lowest possible rates, sometimes absurdly inadequate. A new law is before the Reichstag now which increases the length of the maximum treatment from thirteen to twenty-six weeks and requires venereal diseases also to be insured against. Hitherto the societies have ignored the venereal diseases. If this law goes into effect all the present contracts with the medical attendants of the societies will have to be modified to conform to the new conditions or otherwise the work of the physicians will be vastly increased without any more pay. The profession throughout the country has been organized, and there is every prospect that the day the law goes into effect, July 1, the medical attendants of all the societies will refuse to continue their services until new satisfactory pecuniary arrangements have been made, and other physicians will not take their vacant places. In short, the physicians have organized a general strike all along the line on the principle: "If you want peace, prepare for war." The societies have been counting on the usual inertia and lack of organization among physicians to accomplish their aims of the minimum of expense for the maximum of medical services, but the decided stand being taken by the united profession will undoubtedly have its effect and the contemplated strike not prove necessary. The strike at Mülhausen has been arbitrated and a temporary peace restored, but at Gera the conditions remain the same and the managers of the societies are compelled to pay for medical attendance for their members at the ordinary rates for a physician's services or let them go without. As a minor matter, the profession in Germany is working to introduce "the American plan" of free choice of the physician by the patient, and many of the new societies are organized on this basis.

LONDON LETTER.

Mr. Jonathan Hutchinson's Investigation of Leprosy in India.

The return of Mr. Hutchinson from India has been followed by a lengthy editorial and evidently inspired article in the "Times" on his tour of investigation. If Mr. Hutchinson can not be said to have established the fish hypothesis which he advocates with all his characteristic pertinacity, he has once more shown that combination of keenness of observation, originality of suggestion and dialectic skill which give him a unique position among the clinicians of this or perhaps any age. His searching cross-examination in the cases of lepers said never to have eaten fish with his recent suggestion that leprosy can be communicated from person to person by "commensal contagion" (eating food from the sore hands of lepers) has demolished the objection of those who said that Indian experience was opposed to him. Further, he has brought forward a number of new facts which at least ought to cause those who do not seriously regard the fish hypothesis to pause. Mr. Hutchinson visited asylums at Colombo, Madras, Calcutta, Purulia Asonsal, Agra, Tarn Taran, Jullundur and Bombay. In several instances the asylum visited was chosen in consequence of statements that the inmates were not fish eaters. But nowhere were the facts strongly opposed to the fish hypothesis. In Ceylon all had been fish eaters. At Madras and Calcutta in each asylum a single high-caste Brahmin denied having eaten fish. At Agra there was one doubtful exception. At Agra, Tarn Taran and Jullundur there were several. The untrustworthiness of the documentary evidence, if not subjected to criticism on the spot, was remarkably illustrated at one asylum in the Punjab. A tabulated schedule was prepared for Mr. Hutchinson by the native medical superintendent, according to which nearly 40 men alleged that they had never eaten fish. On questioning them one by one Mr. Hutchinson found that only one persisted in his denial, and he said he had not eaten fish because he "did not like it." The greater part of those who denied having eaten fish were patients in whom the disease had begun in early life; and in these food communication is especially likely to occur. Children would easily take food contaminated by the hands of leprous relatives. Passing from the removal of objections to positive evidence Mr. Hutchinson brings forward the following facts: The proportion of leprosy in the whole of India is 5 per 10,000. On the little island of Nunicoy, which exports fish, and where the inhabitants are said to eat four fish meals a day, the proportion is nearly 150 per 10,000. The records of the Matunga asylum at Bombay are most suggestive. The Hindus, who constitute the bulk of the inmates, come mostly from the great fishing district on the coast south of Bombay. During the eight years investigated no Jain and only one Parsee was admitted. The Jains are strict vegetarians and the same statement concerning their absence might probably be made of every asylum in India. The report of the Matunga asylum reveals a fact still more remarkable. One column is devoted to "Salsette Christians." The totals are Mussulmans, 324; Salsette Christians, 369. Yet the Mussulman population of Bombay Presidency is very large and the number of Salsette Christians very small. The latter term is applied to the converted natives of the little island of Salsette, which is north of Bombay and now connected with it by a road. It has a population of 50,000, largely engaged in fishing and fish-curing. The Salsette Christians are all Roman Catholics and are descendants of converts made by the Jesuits in the time of the Portuguese occupation and observe the fish fast days of their church. During the eight years no other Christian community in the presidency supplied a single leper to the asylum. Mr. Hutchinson's general conclusion is that as regards leprosy in India there are no facts which controvert or render untenable the fish hypothesis and that there are some which afford to it a support which he considers unassailable.

A New Method of Immunization.

A most important advance in the art of immunization has been rendered possible by the recent discoveries in physics by Professor Dewar which have lead to the liquefaction of air and other gases. At the Royal Society Dr. Allan Macfadyen described an investigation he had made in conjunction with Professor Dewar which promises a prophylactic and therapeutic agent in the treatment of typhoid fever, which may replace the anti-typhoid "vaccines" and anti-typhoid sera in use. So far all attempts to separate the toxin from the cell protoplasm of the typhoid bacillus have failed. Hence such "anti"-sera as have been produced are bactericidal or anti-bacterial and not actively antitoxic. For some years Dr. Macfadyen has been experimenting with bacteria which form intracellular or so-called "insoluble" toxins. He attempted at first to obtain the cell juices by trituration of the bacteria with fine sand and subsequent expression by a hydraulic press. But in all these operations heat is evolved and induces chemical changes in the juice obtained. Professor Dewar's observations on the liquefaction of various gases showed that at very low temperatures all chemical interchange ceased, although life was not necessarily destroyed. Dr. Macfadyen, working in conjunction with Professor Dewar, found that many species of bacteria could be exposed to the temperature of liquid air for considerable periods of time—in some cases as long as six months—without loss of vitality. At this temperature bacterial cells are frozen into hard fragile masses which can be successfully triturated *per se* without the possibility of autolytic changes, and the cell plasma can be subsequently obtained from the disintegrated mass. The cell juice obtained in this manner from the *Bacillus typhi abdominalis* is extremely toxic, although no living typhoid bacilli are present. This typhoid cell juice was employed in the immunization of animals which yielded an "anti" serum both bactericidal and also antitoxic. They were completely protected against lethal doses of living typhoid bacilli or of toxic cell plasma. Further animals inoculated with lethal doses of living bacilli or of toxin and some time later injected with curative doses of the "anti" serum recovered. This new method of immunization has wide possibilities for it is applicable to many infectious diseases.

The Bacteriology of Conjunctivitis.

At the Æsculapian Society Mr. E. W. Bremerton read an important paper on this subject based on an examination of 100 cases. His cases showed that in the various infections the risk of sloughing of the cornea was greatest in the following order: 1, streptococcus; 2, gonococcus; 3, staphylococcus; 4, diphtheria bacillus; 5, Koch-Weeks' bacillus, and 6, staphylococcus albus. Fifty per cent. of his cases of ophthalmia neonatorum were gonorrheal; and cases thought gonorrheal, which quickly recovered, were found to be pneumococcal.

Societies.

COMING MEETINGS.

AMERICAN MEDICAL ASSOCIATION, FIFTY-FOURTH ANNUAL SESSION, NEW ORLEANS, MAY 5-8.

Illinois State Medical Society, Chicago, April 29-May 2.
Arkansas Medical Society, Jonesboro, April 30-May 2.
Association of American Medical Colleges, New Orleans, May 4.
American Proctologic Society, New Orleans, May 5.
Kansas Medical Society, Concordia, May 6-9.
American Urological Association, New Orleans, La., May 8-9.
American Academy of Medicine, Washington, D. C., May 11-12.
American Therapeutic Society, Washington, D. C., May 11-13.
Oklahoma Territorial Medical Association, Guthrie, May 12.
American Association of Genito-Urinary Surgeons, Washington, D. C., May 12-14.
American Dermatological Association, Washington, D. C., May 12-14.
American Surgical Association, Washington, D. C., May 12-14.
American Orthopedic Association, Washington, D. C., May 12-14.
American Pediatric Society, Washington, D. C., May 12-14.
Association of American Physicians, Washington, D. C., May 12-14.
American Medico-Psychological Association, Washington, D. C., May 12-15.
American Ophthalmological Association, Washington, D. C., May 13-14.
Association of Military Surgeons of the United States, Boston, May 19-21.
New Hampshire Medical Society, Concord, May 21-22.
North Dakota State Medical Society, Bismarck, May 21-22.
South Dakota State Medical Society, Mitchell, May 27-28.
Connecticut Medical Society, Hartford, May 27-28.

American Academy of Medicine.—The twenty-eighth annual session will be held at Washington, D. C., May 11 and 12.

Caldwell County (Texas) Medical Society.—At the annual meeting in Lockhart, April 14, Dr. John B. Holt, Lockhart, was elected president, and Dr. Ross, secretary.

Dubuque (Iowa) Medical Society.—The notice of the coming semi-centenary meeting of this society, which appeared in The Journal of April 25, should have read "fiftieth" and not "fifteenth" anniversary.

Graves County (Ky.) Medical Society.—In addition to the officers noted as having been elected, Dr. Jefferson D. Pryor, Mayfield, was elected vice-president and Dr. Herbert H. Hunt, of the same city, treasurer.

Central District (I. T.) Medical Society.—At the annual meeting, held in South McAlester, April 14, Dr. Alfred Griffith, South McAlester, was elected president; Dr. W. H. Cleckler, Wilburton, vice-president, and Dr. LeRoy Long, Caddo, secretary and treasurer.

Hartford County (Conn.) Medical Association.—The one hundred and eleventh annual meeting was held in Hartford, April 15. Dr. Howard O. Allen, Broad Brook, was elected president; Dr. George R. Shepherd, Hartford, vice-president, and Dr. William G. Craig, Hartford, clerk.

Pee-Dee (S. C.) Medical Association.—At the fifty-sixth annual meeting held in Darlington, April 8, Dr. F. H. McLeod, Florence, was elected president; Dr. A. T. Baird, Darlington, vice-president; and Dr. James M. Earle, Darlington, secretary and treasurer. The next meeting will be held in Florence, in October.

Silver Bow County (Mont.) Medical Association.—At the annual meeting, February 25, the following officers were elected: Trustees, Drs. Thomas J. Murry, Thomas J. Sullivan, John W. Gunn, Erasmus D. Leavitt, and Thomas A. Grigg; president, Dr. Thomas J. Sullivan; vice-president, Dr. Louis Bernheim, and secretary, Dr. Grace W. Cahoon, all of Butte.

Central Railroad of Georgia Surgeons' Association.—The annual meeting was held in Columbus, April 14. Resolutions were adopted on the death of Drs Benjamin R Dostor, Blakely, Ga, and Robert F Harper, Ozark, Ala Dr Samuel C Benedict, Athens, was elected president, Dr Charles Hickes, Dublin, Ga, vice president, and Dr W Darracott Travis, Covington, Ga, secretary and treasurer

Fairfield County (Conn) Medical Society.—About fifty members were present at the one hundred and eleventh annual meeting held in Bridgeport, April 14 Dr William B Cogswell, Stratford, was elected president, Dr Frederick Schavoir, Stanford, vice president, Dr Herbert F Smyth, Bridgeport, clerk, Dr Edwards M Smith, Bridgeport, secretary, and Dr William J Tracy, Norwalk, county reporter

Florida Medical Association—The thirteenth annual meeting was held in St Augustine, April 8 and 9 The following officers were elected· Dr DeWitt Webb, St Augustine, president, Drs John McDiarmid, De Land, and Joseph N Fogarty, Key West vice presidents, Dr J D Fernandez, Jacksonville, secretary treasurer, and Dr Edward N Liell, Jacksonville, librarian The 1904 meeting will be held in Live Oak

Medical Association of Georgia—The fifty fourth annual meeting was held in Columbus, April 15 The following officers were elected Dr Henry McHatton, Macon, president, Drs James H McDuffie, Columbus, and Elmer C Thrash, Oakland, vice presidents, Dr Alexander Mack, Hawkinsville, censor, and Dr. Floyd W McRae, Atlanta, delegate to the American Medical Association The next meeting is to be held in Macon

New Mexico Medical Society—This society met for its twenty second annual session at Las Vegas, April 7 The following officers were elected Dr G C Bryan, Alamogordo, president, Drs Edwin B Shaw, East Las Vegas, T B Hart, Raton, and Samuel D Swope, Deming, vice presidents, Dr J Frank McConnell, Las Cruces, secretary and delegate to the American Medical Association, and Dr George W Harrison, Albuquerque, treasurer

Adams County (Ill.) Medical Society—The annual meeting was held in Quincy, April 13, when the following officers were elected: President, Dr William W Williams, Quincy, vice presidents, Drs Amos D Bates, Camp Point, and Henry Hart, Quincy, secretary, Dr John A Koch, Quincy (re elected), treasurer, Dr Levin H A Nickerson, Quincy (re elected), censors, Drs Joseph Robbins, Charles D Center and Robert J Christie, Jr, all of Quincy, delegate for two years to the state society, Dr Edmund B Montgomery, Quincy, and alternate, Dr William E Gilliland, Coatsburg

FOURTEENTH INTERNATIONAL CONGRESS OF MEDICINE.

Held in Madrid, Spain, April 23-30, 1903

The President, M le Prof Julian Calleja y Sanchez, presiding

[*By Cablegram from our Special Correspondent*]

MADRID, APRIL 24, 1903

The Fourteenth International Congress of Medicine opened in Madrid, Spain, Thursday, April 23 The organization and provision for the reception of members was miserable, and hotel accommodations inadequate Many passengers on the "Irene" arrived late, being detained in Seville

The Opening Sessions.

On Thursday afternoon the inauguration in the Opera House was attended by King Alphonso XIII and the queen mother

The attendance, as announced by the Secretary, M le Dr Angel Ferandez Caro, was 7,000, about half of whom were foreigners The United States was seventh in attendance, with 200 present

President Calleja, in his opening address, emphasized the progress of the century, laying special stress on the cell doctrine, and the theory of epigenesis in relation thereto He considered that perhaps the greatest advance was in bacteriology, which now dominates medicine

Congratulatory addresses were made by Leyden, Schroetter, Brouardel and Pavy.

The second day was largely given to organization and election of officers The general reports were for the most part postponed

Social Entertainment.

The evening of the first day closed with a grand ball, 500 delegates being present, in the City Hall Among the other social events was a full dress reception, on Friday evening, in the palace by the king and queen On Wednesday evening a party was given in the Royal Gardens Saturday there was an excursion to the Escurial [This is an immense monastery outside Madrid, considered one of the wonders of the world] On Sunday a special bull fight was given for the benefit of the visitors, and on Monday an excursion to Toledo

---

THE SCIENTIFIC·PROCEEDINGS

The most important papers were in pathology, medicine, obstetrics and gynecology

Treatment of the Autointoxications Due to Overaction of the Nervous System.

Prof Alexandre de Poehl of St Petersburg described a vicious circle in nervous autointoxications in which the chief agent is adrenal Deficient tissue oxidation sets free a number of organic acids in the blood Poehl has found adrenal in many tissues, it is dissolved out by the hyperacid blood serum and, as a reducing agent, still further intensifies the acidification of the blood Senator has recommended spermin for this condition for the reason that it best combats the hyperacidity

A New Antipyretic

Lumiere and Chaumier read a paper on cryogenine, which is a semicarbazide This is a powerful antipyretic, the dose being from ½ to ¾ gram It lowers the temperature from one to three degrees, acting immediately, while the maximum effect is obtained in three hours The effects last from six to forty eight hours The results vary with the nature of the disease There was not found any disturbance of urine, digestion or of the nervous system even of the child, nor is a toleration established

Tuberculosis

Dr Regurier of Nice presented a paper on "The Clinical Types of Pulmonary Tuberculosis and Their Therapeutic Indications" For rational and scientific treatment one must have an accurate clinical subdivision of the various types The only logical basis for such a subdivision is the degree of resistance which the organic economy opposes to the microbic infection There are three grades of reaction of the organism: 1, unbending resistance, 2, less firm resistance, and 3, entirely inadequate resistance On this basis the author suggests a very complete regrouping of the various clinical types hitherto generally recognized

The Dynamogenic or Inhibitory Action of Light Massage.

Dr Saquet of Nantes read a paper on the comparative dynamometric measurements of the power of the hands taken before and after massage had been administered As a rule there is an increase in power, in other cases there is apparently a diminution in the register of the dynamometer, but even in such cases the equilibrium is generally restored within a quarter of an hour

Physicotherapy; Its Indications and Its Advantages.

Prof J Riviera of Paris praised most highly the physicotherapeutic agents, viz, electricity, heat and light They act principally by stimulating the emunctory organs, by altering metabolism and by influencing the distribution of the blood to the various parts of the body They are particularly of value in the treatment of city diseases such as gout, arthritism, dyspepsia, nervosity, all types of dystrophy, "uterine patients," and all the many chronic cases which have hitherto resisted medical treatment

Ferruginous Waters for Chlorosis.

Dr E Guilleaume of Spa said that the same circulatory conditions which give the subjective symptoms of chlorosis prevent the proper assimilation of iron as a medicine The ferruginous baths (carbonic acid gas) rapidly improve the general condition by improving the circulation, and so, without directly affecting the hemoglobin, further a cure by rendering possible the assimilation of the iron given internally.

Argon and Helium in Mineral Waters.

Dr. A. Popskin said that argon and helium, the recently discovered elements, have been identified in various waters, Cauterets, Harrowgate, Voslau, etc., but as they do not appear to enter into the biochemical processes and can not be recovered from animal or vegetable bodies by analysis, they, therefore, probably exercise no therapeutic action in the waters.

Syphilis and Hydrotherapy.

Dr. H. Keller of Reinfelden said that physiotherapy is as important as medicine in the treatment of syphilis. This treatment comprises hygiene, hydro-mineral treatment and hydrotherapy. They should be combined for syphilitics who are of the lymphatic or arthritic constitution, or anemic or debilitated. In the severe cases, it is really specific. It is indicated in cases of idiosyncrasy against mercury. Sulphurous, chlorinated and iodid springs are of especial value.

Tuberculosis and Hydrotherapy.

Dr. M. Cayeux of France said that certain waters, by their stimulating action, serve to fortify the organism against the attacks of the bacteria, while, by their peculiar composition, they combat the catarrhs, congestion and other "para-tuberculous" manifestations of the disease. He detailed the special indications for various types of waters.

The Causes of Tumors.

In the section on pathology, Doyen of Paris read a paper on "The Micrococcus Neoformans and Tumors." He said that all neoplasms are due to parasitic infection, the process being analogous to the inflammatory growth of actinomycosis. The neoplasms of rapid growth are due to the *Micrococcus neoformans*, which has been found in the growth. Pure cultures have been made on bouillon, and when inoculated into animals inflammations or neoplasms have been produced in them. He further stated that the toxins produced a reaction in cancerous individuals analogous to the action of tuberculin.

Parasites and Tumors.

Rio of Madrid described a type of sarcoma due to coccidia as well as granulomata of chronic growth, with central necrosis. These involved the skin, muscles and organs.

The subject was further discussed by Dr. O. Israel of Berlin, who reviewed the modern theories of parasitism in tumors. He said that tumors represent simply the reaction of the tissues to an unnatural stimulus, which leaves the supposition of a uniform etiologic factor without sufficient basis. The sarcoma, carcinoma, etc., are caused in the same manner, but by a very different stimuli. If, however, ectogenous parasites are proved to be the actual causative factors, it must be by demonstrating that they conform to the requirements laid down by Koch. The first one, inoculation, appears to have been proven, but reproduction of the disease has not. The second requirement, detection of the germ, has not been met. Israel declared that the plant parasites which are found are commensals rather than the direct cause, and the animal parasites are artefacts. Koch's third requirement, pure cultures, has never been satisfied as regards the protozoa.

Finally, the production of neoplasms by the inoculation of cultures has never succeeded, apparent successes being in reality inflammatory neoplasms. The true explanation of tumors is to be sought in cytobiologic conditions--pathologic increase in the proliferative tendencies of the cell.

Blastomycetic Lesions.

Dr. A. Bushke reviewed our knowledge on blastomycetes. Especial attention was paid to the *Oidium mycosis* of the Americans. Infection is through the skin and mucosæ, probably through lesions, but the mode has never been ascertained. There are three types: 1, blastomycetic septicemia; 2, localized infection, and 3, the typical, slow-growing blastomycosis. Dr. Bushke described the various modifications of the latter type in detail and gave their pathology. Because of its great tendency to internal metastases, the disease is more fatal in man than in animals.

Artificial Imitation of Pathologic Cell Conditions.

Dr. Unna of Hamburg showed how the various types of cytoplastic and raryoplastic degeneration might be induced on the microscopic slide by means of the action of various solutions.

Specific Sera.

Paltauf of Vienna emphasized the value of agglutination in order to determine the specificity of germs. The sera of horses immunized by streptococci of scarlatina by Moser agglutinated the same cocci in high dilution, but did not have this effect on the cocci of erysipelas or phlegmon.

Implantation of Bone.

Cornil of Paris declared that his investigations showed the announcements of Bartels to be premature. Bartels had said that his researches showed that pieces of dead and living bone were equally efficacious. Dr. Cornil said that both implantations are absorbed and replaced by fresh tissue, but in the case of living pieces granulations are more active and abundant. His experiments had been on the craniums of dogs.

Malaria.

Drs. Barrera and Pittaluga of Spain made important contributions on paludism. They claimed that Grassi, not Ross, was the real discoverer of the transmission of the ameba. The three varieties, quartan, tertian and estivo-autumnal, are due to separate species, and the recrudescenes of malaria are "bridges" which unite successive seasonal epidemics. Following the parthenogenesis of the organisms they seek the internal organs, where they remain during the latent periods. This is exemplified by the crescents. The multiplication takes place by a nuclear division, generally in June; thus young mosquitoes are reinfected. The quotidian type may be due to the estivo-autumnal variety or to a rapid development of the tertian or an independent type.

Acute and chronic estivo-autumnal varieties are the most diverse. He described the hydrographic conditions which suit the plasmodium. Prophylaxis directed toward extinction of the mosquito is most expensive and inefficacious, but mechanical protection of man is efficacious. Paludism in man is the proper point of attack. Quinin is best given during the latency of the disease in winter.

Ascoli of Rome emphasized the importance of studying the recrudescences in Italy. An epidemic of malaria appears annually at a time in June when there are relatively extremely few infected mosquitoes. Many cases have a malarial history.

There are two types of recrudescence, with brief and long intervals, the former being due to imperfect extinction, the latter to parthenogenesis. The latter connects successive epidemics. He emphasized the fact that mosquitoes are always born healthy, but man is the permanent host.

Dr. F. Hauser of Madrid argued that the anopheles do not furnish the only intermediate host for the malarial parasite. Under favorable conditions the germ might live in humid earth in some unknown form, and the disease might flourish in regions free from mosquitoes. From the earth it may be conveyed by the air or by mosquitoes to the blood; for example, the inhalation from dried marshes or the drinking of water infected by the bodies of dead mosquitoes could infect. Mosquitoes dying in marshes set free the organism, which then infects man through the medium of the air.

Obligatory Report of Tuberculosis.

In the section on hygiene, epidemiology and technical sanitation Dr. H. Tabor of Prague recited six very strong arguments for the general prophylaxis of tuberculosis, based on reports of every case of tuberculosis, of death from the disease, or of change of lodging of diseased persons.

The Intellectual Life.

Dr. L. Bares of Saint-Gandens said that intellectual labor predisposed to digestive disturbances, to disturbances of nutrition, and to nervous break down. A severe alimentary hygiene was recommended, excluding rich indigestible foods as well as alcohol and tobacco. Exercise in the open air, open bowels, an active skin, and the drinking of milk are essential for the brain-worker. Sleep is the criterion of the nervous condition and should be undisturbed.

Hysterectomy in Acute Infections.

In the section on gynecology and obstetrics, Dr. Pinard of Paris read a paper on the above subject. He said that except for definite cause, such as trauma or putrifying fibroma, there is no rational indication for removal of the uterus. The autopsy never reveals localized lesions in the uterus. The presence of bacteria in the blood does not affect the prognosis. The bacteriology of uterus is valueless clinically for it is impossible to localize the infection in the uterus or to determine the advisability of operation.

Cortajena of Madrid said that general infections diminish the importance of the uterus as the primary agent. Chronic infections never justify hysterectomy. The proper moment for operation is almost impossible to determine. He urged conservative surgery of the adnexa.

Treub of Amsterdam said that radical operations have a mortality of 6 per cent. and do not guarantee cure. Such cases have prolonged disagreeable consequences. Conservative operations have a mortality of two per cent. and generally suffice, but may demand secondary operations. They never induce constitutional disturbances. For salpingo-oöphoritis medical treatment generally suffices, but if not, repeated posterior colpotomies are preferable. In rebellious or sterile cases conservative abdominal operations were advised, but not excision, while for tuberculosis hysterectomy must be made.

The other sections have only organized or listened to unimportant papers.

(To be continued.)

BOSTON SOCIETY OF MEDICAL SCIENCES.

Meeting held at Harvard Medical College, April 28, 1903.

Prof. H. C. Ernst in the chair.

[By telegraph from our Regular Correspondent.]

Discovery of the Germ of Smallpox.

More than five hundred of the prominent members of the medical profession of Boston gathered in the largest amphitheater of the Harvard Medical School to hear Prof. W. T. Councilman make his announcement of the discovery of the germ of smallpox. Dr. Councilman stated that for two years the study has been carried on under his supervision by Drs. Brinckerhoff, McGrath, Tyzzer and Thompson in the laboratories of the Smallpox Hospital at Galloupes Island and in the Detention Hospital on Southampton street, with the cordial cooperation of the Boston Board of Health.

All the material obtained was brought to the Harvard Medical School and thoroughly studied there. First vaccinia was studied and then the contents of the vesicles and pustules, but no definite germ could be here detected because of the vast number of bacteria of varying kinds always present. Finally an anatomic study of the lesions of the disease revealed the organism with its definite cycles of development. In the deep epithelial cells of the skin there were found bodies one micron in diameter, which have also been noted by other observers. They stain easily, are homogeneous, increase in size, their structure gradually becomes granular, their shape irregular, and they are surrounded by little circles more or less resembling amebæ. Occasionally segmentation is evident, the organism splitting into a number of segments.

This is a distinct cycle. There is no change in the nuclei, a vacuole surrounds the organism and grows with it. Suddenly it disappears and peculiar changes are noted in the nuclei, a ring appears and grows, rings appear in its periphery and its structure becomes sponge-like. This finally fills the whole nucleus, which degenerates and sets free the body. It does not much further increase in size, but the structure becomes more complex, the ring-shaped bodies appear, one micron in diameter, and it breaks up into these "spores." We thus have, as in other protozoa, two cycles, the intracellular and the intranuclear, the latter more complex and corresponding to sexual development.

In vaccinia we have only the first cycle, and this is the case also when the rabbit is exposed to smallpox. The monkey being nearer to man, however, gives both cycles. The whole process is complete when the vesicles begin to form. These stages are not found in the vesicles, pustules or crusts, but the "spores" have been found in the blood vessels of the skin. These are probably not the only cause of the later eruption, but prepare the way for the streptococci. Professor Councilman showed a beautiful series of lantern slides made from microphotographs which fully and clearly substantiated each of his statements.

Professor Calkins, professor of zoology at Columbia University, was present and agreed with Professor Councilman in believing the organism a protozoan. He warmly congratulated Professor Councilman and his associates for their investigations and discoveries, and specially noted the advantages of the discoveries in aiding the early diagnosis of the disease. If the organism can be found in the epithelial cells or the blood instead of our having to wait fourteen days for the eruption to appear, valuable time would be saved and the possibilities as regards treatment are evident. The organism belongs to the class of microsporidia.

Miscellany.

Clippings from Lay Exchanges.

LUCKY HE IS NOT ALSO.

"Mr. ——— — ——— is going . . . to have another amputation performed on his limb, as it will not heal on account of the bone being deceased."—"La Junta (Colo.) Democrat," Nov. 29, 1902.

HOW DID HE RECOVER FROM A MORTAL WOUND?

"Dr. — — ———, who was mortally wounded . . . and whose life hung in the balance for weeks, has fully recovered and resumed the practice of his profession."—"Burlington (Iowa) Hawkeye."

WHERE DID HE WEAR IT?

"Ottumwa, Iowa, Oct. 23, 1902.—Because her husband threw a bucket of water on her while she was asleep, . . . Mrs. ——— ——— procured a shotgun and blew her husband's stomach off."—"Chicago News."

SOME ARE.

"The ——— County Medical Association met. . . . Written papers were read by . . . and by Dr. ——— on antepartum and postpartum hemorrhoids."—"Memphis (Tenn.) Commercial-Appeal," April 8, 1903.

TRACHEO-ESOPHAGEAL ANASTOMOSIS?

"Coughs up a Luzon worm. . . . His stomach had been the home of . . . worm . . . with a most peculiar swelling at the neck. . . . This was undoubtedly the part by which the worm got caught in his windpipe when he began to cough it up."—"Brooklyn Eagle," April 18, 1903.

Professional Secrecy in the French Courts.—The "Journ. de Méd. de Paris" of November 9 gives the particulars of a recent suit involving a physician, which has caused much discussion in France. Dr. A. has for twenty years been the official duly appointed by the municipal authorities of Marseilles to pass on and certify the applications for committing insane persons to asylums. In a recent case a man was sent to an asylum, but was released after his attack of insanity had subsided, and sued his wife for having had him unjustly declared insane. She cited as witnesses the attending physicians, among them Dr. A. The latter, believing that his certificate was a public matter, knowing that it had passed through a number of hands, did not hesitate to testify to the effect of its contents. The husband at once sued him for $4,000 damages for violation of professional secrecy. The local court acquitted Dr. A., as it was generally understood that his certificate was a quasi-public matter, but the case was appealed, and the higher court decided against him, claiming that he had certainly violated professional secrecy in the affair.

Eruption from Confetti.—Foveau de Courmelles recently reported to the Paris Acad. de Méd. a case of a cutaneous eruption produced by confetti. The probable mode of poisoning was by the penetration of the anilin dyes from the confetti alighting on cracks in the lips.

Experimental Hypnotism; Effect on Circulation.—Berillon contributes an article on this subject to the "Journ. de Med. de Paris," describing the effect of hypnotism on several hysteric subjects, including those otherwise sound and those with functional circulatory disturbances. The sphygmograms show a remarkable influence of the circulation under the suggestion by the hypnotizer. The pulse and also the heart action could be retarded, accelerated or rendered regular at will, and the arterial tension modified. He also mentions that one of his friends, in a series of sphygmographic researches on himself, was alarmed to discover, after a time, marked arrhythmia, which, however, subsided so soon as he abandoned his researches. The close concentration of the attention directed by suggestion on certain organs, certain functions or certain parts of the body, leads to an actual polarization of the nerve force at this point. In one case of traumatic neurosis, with palpitations, arrhythmia and incessant tremor, all these symptoms subsided in the hypnotic sleep, as also the pronounced tachycardia in another case.

Ankylostomiasis in Cuba and Mexico.—Physicians in these two countries are awaking to the realization of the fact that the numerous cases of progressive anemia observed there and hitherto assumed to be malarial cachexia are, in reality, in many instances true ankylostomiasis. Agramonte describes his experience at Havana in the "Revista Med. Cubana," 1, No. 4. He found the *Uncinaria americana* in 16 cases of progressive anemia, 12 of which had been previously diagnosed as malarial anemia or cachexia and 3 as splenic anemia. He reports the clinical course of a few cases and illustrates the differences between this form of the uncinaria and the better known *U. duodenalis*. Manuell has had a similar experience in Mexico, having found 5 cases of ankylostomiasis in a brief time so soon as he commenced to examine for it. He remarks that these cases in the past have probably been cited as examples of the failure of quinin in certain manifestations of malaria. Two of his patients had been employed in Yucatan, 2 in the tobacco fields of the national valley and 1 came from a mining district. The trichocephalus accompanied the parasite in every instance, and in one case ascarides were also present. He mentions in his communication to the "Revista Médica" of Mexico, xiv, 11, that no one before has ever mentioned finding the trichocephalus in Mexico.

Aqueous Preparations of Menthol.—Blondel found that if menthol were given to a dog at the same time or shortly after an emetic dose of ipecac, there was no vomiting. Chauffard also noted that ipecac given with menthol failed to produce an emetic effect. This power to inhibit vomiting renders menthol very valuable in vomiting of reflex origin. Crêsantignes gives several formulas in the "Journ. de Méd. de Paris" for preparing an aqueous solution of menthol. Ordinarily it does not dissolve in water. He uses the tincture of quillaja saponaria, 5 gm. to 3 or 5 cg. of menthol, adding, after they are mixed and the menthol is dissolved, 10 gm. of neutral glycerin in distilled water q. s. to make 125 c.c. This is taken by the tablespoonful. For local application in case of frontal headache, he applies a mixture of 15 to 30 cg. of menthol dissolved in 10 gm. of tincture of quillaja and distilled water to make 155 c.c. This is applied on a folded compress. After three to five minutes the compress is replaced by one dipped in pure water, after which the menthol compress is applied again, and so on. For a mouth wash and gargle he prefers the formula: menthol 10 to 20 cg. in 20 gm. tincture of quillaja and distilled water, or a saturated solution of boric acid q s. to make a quart. The "Medical Standard" says that the first formula given "illustrates the absurdity of some of the prescriptions recommended in the journals for medicinal use. This mixture is to be used as a gastric sedative. The addition of the quillaja defeats this very end, since it is a decided, often a violent irritant; it is an active poison—a cardiac depressant, and a bill forbidding its use as a foam-producing ingredient of soda fountain drinks has been introduced in at least one state. The art of the pharmacist has in this case over-shadowed the practical end of the physician, who, as a matter of fact, would find the simpler spirit of peppermint or peppermint water just as effective."

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

CAUSE OF DEATH WANTED.

WATERTOWN, S. D., April 16, 1903.

To the Editor:—The following case has proved somewhat of a conundrum to me especially as no postmortem examination was allowed.

Cecil G., about 5 years of age, with a previous good history except a recent recovery from a mild attack of la grippe, was placed under chloroform anesthesia for the purpose of removing enlarged tonsils. The anesthesia was not complete, first, because the operation was expected to be of such short duration that it was not deemed necessary to take the time; second, in consequence of some danger to blood getting into the bronchi if reflex was entirely abolished.

One tonsil was easily removed, but some difficulty was experienced in getting the other engaged in the tonsillotome, principally in consequence of the contraction of the throat, and finally it was seized by a vulsella and removed with serrated scissors.

The child was immediately inverted to facilitate the flow of blood from the mouth, the child meanwhile struggling and crying with returning consciousness, when it suddenly stiffened and breathing and heart action ceased at almost the same instant.

Artificial respiration for over an hour, with subcutaneous injections of normal saline solution, failed to obtain any result. What would be supposed to be the exciting cause of death?

H. H. CLARK.

Correspondence.

Priority in Technic.

BROOKLYN, April 20, 1903.

To the Editor:—In the April 4 number of THE JOURNAL one of your contributors, in an article entitled "A Few Practical Points in the Technic of Nephrorrhaphy and Herniotomy, and a New Modification of Alexander's Operation," publishes, as his own, three operative procedures so long identified with the names of other surgeons that I can not forbear calling your attention to the fact.

In the second paragraph of his article your contributor states that he has employed the methods described since 1890, claiming originality, by implication, for the latter and dating the claim from the time mentioned. It may be true that Dr. Canac-Marquis was the first to apply the "crossed" or figure-of-eight suture in nephrorrhapy, although, if my recollection serves me right, I used it in the winter of 1889 and 1890 in perineorrhaphy, nephrorrhaphy, herniotomy and for the closure of abdominal and other incisions in general. This part of the subject is unimportant, however, since this was the period of development of the possibilities of the "crossed" or removable layer suture in my work, and prior to any publication of my own on the subject, or, so far as I then knew, of the publications of others as well. Since, also, your contributor does not employ the figure-of-eight suture to anchor the kidney, but only to close the wound and since, further, he does describe its use in closing the wound of the herniotomy operation, I feel that failure to give credit for these applications of the method justifies the present contribution.

In the transactions of the American Surgical Association for 1891 there appeared my first communication relating to a removable layer suture, illustrated by woodcuts. This suture was again described, with a modification relating to the method of finally securing the ends of the suture. Still later the method was again described in illustration of its application to the closure of the wound of the abdominal wall following the operation for appendicitis in a "Treatise on Appendicitis," edition of 1894. In the 1900 edition of the latter work this suture, together with a still further modification of the method of securing its ends, is again described and illustrated. Quoting from the first of these, I said:

> It occasionally happens . . . that the different layers of tissue passed through in the course of the operation must be sutured separately in order to insure a good result. Here catgut will not answer, for the reason that it is dissolved or, at all events, weakened, before it has answered its purpose, and the sutured layers separate widely in spite of every care. To meet the requirements of these cases I have devised a suture which, while it serves all the purposes of a deeply buried layer suture, at the same time can be removed. I have called this the "crossed suture." Silkworm gut or silk may be used for this purpose, but the former is preferable. Both ends of the thread are threaded with needles of the proper curve, and both are passed beneath the lowermost or the deepest layer to be sutured, at sufficient distance from the edge to obtain a good hold thereon. As the thread is drawn through either edge of the layer, the loop is drawn taut beneath. The thread is now crossed, the needle which passed the latter through the outer edge crossing over the inner edge, and that which passed the thread through the inner edge going to the outer. The needles are now passed through the next layer as before, from below upward, securing a firm hold as in the first layer.
>
> The threads are again drawn taut and crossed as before, each time of crossing securing a layer until the surface is reached, the last layer, of course, being formed by the skin itself.

While Dr. Canac-Marquis concludes his operation by the use of "a lead nickel-plated shield threaded and shotted," I have for some years attained the same result in a slightly different manner. Quoting from my book, "A Treatise on Appendicitis," 1900:

> The crossed sutures are tied in pairs on either side of the wound. In order to guard against cutting of the skin from the silkworm gut, the sutures are tied over "bolsters" of sterile gauze or, what I find exceedingly convenient for this purpose, sections of thick-walled tubing of soft rubber (aspirator tubing) are used, the silkworm gut being passed through the lumen of the tubing. . . . This method gives all the advantages of buried layer sutures, and yet places completely within control the length of time the sutures are to remain in place. . . . Removal is accomplished by cutting the suture beneath the bolster on one side, and making traction on the other end of the thread.

While my first article was in the hands of the printer, and after I had employed the method of thus placing a removable layer suture in practically all the situations in which it is applicable, Well's translation of the first edition of Pozzi's work on gynecology appeared. I then became aware, for the first time, through a very scant reference to the matter by Pozzi (Vol. II, pp. 980, 981), that a similar suture had been described by Heppner for the perineum.

Taking up, next, Dr. Canac-Marquis' "Technic of Herniotomy for Radical Cure of Hernia": Bryant, as far back as 1889, advocated the use of the hernial sac itself to form a pad of resistance to intra-abdominal pressure. In the "Transactions of the New York State Medical Association," 1889, under the heading "Treatment of Hernia," Dr. Bryant says:

> I can not close this portion of the subject without calling to your attention a somewhat newer method of operating that I have practised on three distinct occasions. It certainly has some features that commend it. . . . It is performed by weaving the sac. after its separation and its neck has been tied with catgut, into the pillars of the ring.

He then illustrates slits through which the sac is woven back and forth, "and finally the whole mass is quilted with deep stitches of catgut."

Though the details of Bryant's old operation, since abandoned, differs somewhat from your correspondent's, still the fundamental principle involved remains the same, and, "honor where honor is due."

In regard to Dr. Canac-Marquis' "New Modification of Alexander's Operation for Shortening the Round Ligaments," I would recall to your attention the fact that in the "Annals of Surgery," 1896, occurs a paper by Robert Abbe, entitled "Fixation of Round Ligaments in Alexander's Operation." After referring to a previous method of his own, Abbe says:

> The idea occurred to me of utilizing the round ligament itself for the double purpose of sewing up the inguinal canal and securing the ligament immovably.
>
> This, I found, was easily accomplished when the ligament was drawn out four inches, as was always readily done. . . . The ligament was drawn on until the uterus was firmly held well forward. The needle and loop now drew the ligament through new punctures on either side of the canal, crossing it to become a continuous suture for the canal. Three such stitches completely closed the canal up to the spine of the pubis, and left more than an inch and a half of ligament over. This was turned back over the last portion of the wound and stitched to it by one fine catgut stitch. . . .
>
> The use of living tissue as a suture thus serves the double purpose of fixing the uterus immovably and binding the canal permanently.

This is identical with your correspondent's method, except in the minor details of closing the superficial structures.

Unless your contributor can substantiate his implied claim as the originator of these three points in technic by publications bearing date earlier than 1889 in the case of the hernia operation, 1891 in the case of the removable layer or figure-of-eight suture, and 1896 in the case of the modified Alexander's operation, the credit of the method of weaving the pillars of the ring together by means of the sac itself should be given to Bryant, that of a removable suture to Heppner and myself, and that of employing the round ligament to close the inguinal canal and at the same time secure the uterus in position in Alexander's operation to Abbe.

GEORGE RYERSON FOWLER.

Marriages.

CHARLES P. PINCKARD, M.D., to Miss Mary Losey Graff, both of Chicago, April 25.

J. JULIUS RICHARDSON, M.D., to Miss Dorothy Flynn, both of Washington, D. C., April 20.

HUGH G. NICHOLSON, M.D., to Miss Roberta Coleman, both of Charleston, W. Va., April 16.

TASSO OLIVER FELIX, M.D., Downs, Kan., to Miss Neva Lee Trusdle of Kirwin, Kan., April 16.

WILLIAM A. CAMPBELL, M.D., Chicago, to Miss Jeannette E. Halsted, at Muskegon, Mich., April 15.

Deaths.

Matthew Gardner, M.D. McGill University, Montreal, 1871, a member of the American Medical Association; chief surgeon of the Southern Pacific Railway system; a member of the California State and San Francisco County medical societies; eminent in his profession and universally beloved, died at the Southern Pacific Hospital, San Francisco, April 18, a few hours after an operation for appendicitis, aged 56. He leaves an estate of a value estimated at from $75,000 to $80,000.

Joseph S. Eastman, M.D. Missouri Medical College, St. Louis, 1878, one of the founders and first president of the Oakland College of Medicine and Surgery, and a member of the state and county medical societies, died at his home in Berkeley, Cal., April 19, after an illness of six months, aged 48.

Henry Clinton Bunce, M.D. Medical Institution of Yale College, New Haven, 1850, assistant surgeon of the First Connecticut Heavy Artillery in the Civil War, died at his home in Glastonbury, Conn., April 15, after a protracted illness, aged 78.

William Flood Smith, M.D. College of Physicians and Surgeons, Baltimore, 1889, and thereafter professor of anatomy in the same institution, died from pneumonia at the Protestant Infirmary, Baltimore, April 14, after a short illness, aged 38.

John M. Allen, M.D. University of Pennsylvania, Philadelphia, 1840, surgeon of the Fifty-fourth Pennsylvania Volunteers in the Civil War, died at his home in Chester, Pa., from paralysis, after a short illness, April 20, aged 84.

Charles L. Howard, M.D. Medical College of Indiana, Indianapolis, 1896, of St. Paul, Ind., was instantly killed in a collision between an automobile which he was driving and a street car at Indianapolis, April 18.

John F. Gaylord, M.D. Medical Institution of Yale College, New Haven, 1878, a member of the Samoset Medical Association, died at his home in Plymouth, Mass., April 14, after a lingering illness, aged 45.

Sherman Hartwell Chapman, M.D. College of Physicians and Surgeons, New York, 1869, a specialist in diseases of the throat and lungs, died at his home in New Haven, April 15, from heart disease, aged 59.

James M. Brown, M.D. Jefferson Medical College, Philadelphia, 1875, a member of the American Medical Association, died at his home in Philadelphia, April 11, after an illness of several months.

L. Hart Kitchel, M.D. University of Buffalo, 1870, died from concussion of the brain and spine, resulting from a fall two months before, at his home in Alden, N. Y., April 20, aged 57.

Andrew G. Selman, M.D. Transylvania University, Lexington, Ky., 1843, a surgeon in the Civil War, who retired from practice in 1893, died at his home in Indianapolis, April 17, aged 81.

Arthur Jones, M.D. Jefferson Medical College, Philadelphia, 1898, of Bellevue, Ohio, died at his mother's home from pneumonia, April 15, after an illness of one week, aged 37.

Cornelius H. Woodcox, M.D. Bennett College of Eclectic Medicine and Surgery, Chicago, 1890, of Coldwater, Mich., died from heart disease at Gilead, Mich., aged 59.

Uriah M. Gibbs, M.D. University of Nashville, 1897, died at his home in Hanceville, Ala., from the effects of strychnin taken in mistake for calomel, April 18, aged 33.

William M. Griffith, M.D. Hahnemann Medical College, Philadelphia, 1872, died at his home in Philadelphia, April 20, from pneumonia, after a short illness, aged 53.

Frank B. Williams, M.D. New York Homeopathic Medical College and Hospital, 1884, died at his home in Brooklyn, N. Y., from Bright's disease, April 19, aged 39.

William S. Robertson, M.D. Medical College of Virginia, Richmond, 1854, died at his home near Mount Hermon, Va., April 21, after a short illness, aged 72.

Samuel H. Kaighn, M.D. Medical College of Ohio, Cincinnati, 1866, died at his home in Leesburg, Va., April 13, from influenza, after a short illness, aged 69.

Morton M. Dowler, Jr., M.D. Rush Medical College, Chicago, 1865, died at his home in Topeka, Kan., April 13, from consumption, after a long illness, aged 69.

Frederick A. Sweet, M.D. New York University, 1889, chief surgeon of the El Paso and Northeastern Railway, died at his home in Bisbee, Ariz., April 17.

Denman R. Kinsell, M.D. Homeopathic Hospital College, Cleveland, 1857, died at his home in Columbus, Ohio, April 17, after a long illness, aged 75.

Leonard Kittinger, M.D. Hahnemann Medical College, Philadelphia, 1863, died from pneumonia at his home in Wilmington, Del., April 17, aged 68.

George M. MacMillon, M.D. Ohio Medical College, Cincinnati, died April 16, at Sewickley, Pa., from consumption, after an illness of nine months.

A. C. Porter, M.D. Philadelphia University of Medicine and Surgery, 1870, died suddenly at his home in Ashford, N. Y., March 26, aged 67.

Thomas Jefferson Elam, M.D. University of Nashville, 1858, died suddenly from apoplexy at his home near Rucker, Tenn., April 20, aged 71.

Daniel H. S. Tuthill, M.D. Rush Medical College, Chicago, 1885, died from heart disease at his home in Chicago, April 18, aged 43.

John W. De Vaughan, M.D. Vanderbilt University, Nashville, Tenn., 1883, died at his home in Milltown, Ala., April 19, from paralysis.

John C. Willy, M.D. University of Zurich, Switzerland, 1874, died suddenly from apoplexy at his home in New Orleans, April 18.

Henry A. Mix, M.D. Rush Medical College, Chicago, 1864, a surgeon during the Civil War, died at his home in Oregon, Ill., April 22.

Franklin A. Sherman, M.D. Castleton (Vt.) Medical College, 1850, died at his home in Ballston, N. Y., April 22, aged 74.

Charles H. Link, M.D. Baltimore Medical College, 1898, died recently at his home in Burlington Flats, N. Y.

Charles L. Youmans, M.D. Atlanta (Ga.) Medical College, 1895, died at his home in Baxley, Ga., April 8.

Medical Organization.

Sumner County (Tenn.) Medical Society.

The physicians of Sumner County met at Gallatin, April 6, and perfected the organization of a county society, with Dr. L. Miller Woodson, Gallatin, president; Andrew J. Swaney, Gallatin, vice-president, and delegate to the Tennessee State Medical Society, and H. Reese, secretary and treasurer.

Buchanan County (Mo.) Medical Society.

At a meeting of physicians at St. Joseph, April 14, a new county society was organized on the lines suggested by the American Medical Association, with an initial membership of about fifty. Dr. Thomas H. Doyle was elected president; Dr. Thompson E. Potter, vice-president; Dr. J. M. Dunsmore, secretary, and Dr. Joseph J. Bansbach, treasurer, all of St. Joseph. Drs. James K. Graham, Chester A. Tygart and James W. Heddens were named as censors.

Grayson County (Ky.) Medical Society.

The physicians of Grayson County met at Lietchfield, April 14, and organized a county society after a talk from Dr. Charles Z. Aud, Cecilian, president of the Hardin County Medical Society. Dr. John M. Berry was elected president, and Dr. Andrew J. Slayton, vice-president, and Dr. George W. Armes, secretary, all of Leitchfield, and Dr. Henry C. Duvall, Millwood, was elected delegate to the state society. The constitution and by-laws of the American Medical Association was adopted in full.

Four States Reorganize in One Day.

Telegraphic reports from San Antonio, Texas; Lincoln, Neb., and New Orleans, La., announce that on April 29 each of these states adopted the constitution and by-laws recommended by the American Medical Association, with practically no changes. On the same date the Illinois State Medical Society also adopted the same constitution. This makes eight state societies that have adopted practically the same constitution within two weeks.

ASSOCIATION NEWS

NOTES ON NEW ORLEANS.

Final Announcements Concerning the Session Next Week.

The Bureau of Information of the New Orleans session, which will be located on the ground floor of the Artillery Hall, entrance on St. Charles street, announces the following:

Members of the committee will meet all incoming trains May 4 and 5. Placards will be in evidence in each station indicating where these gentlemen will be found.

The bureau will have every facility for supplying all kinds of information; this means male and female clerks, index lists of all visiting physicians and their ladies, railroad schedules, excursion information, telegraph, telephone, stenographer and typewriter, messenger services, guide books, newspapers, cigars, etc. The committee has completed all plans for the meeting and urge all members not located to inquire at the Bureau of Information for rooms.

Members of the profession are advised that badges will be furnished only to those who register as members of the American Medical Association. While the several Sections are open to the profession, the discussions are confined to members. Participation in the several entertainments is restricted as well to the members of the Association and to invited guests.

THE ENTERTAINMENT OF THE LADIES.

Members, with ladies, who have not already notified the committee are requested to leave word at the Bureau of Information as to the number and names of ladies in their party.

The Ladies' Committee announces a trolley ride for the visiting ladies, to start at 11 o'clock on Wednesday, May 6. All to report at 10:30 at the Palm Garden of the St. Charles Hotel.

On Thursday, May 7, at 9:30 at the Palm Garden, a ladies' committee will meet and escort visiting ladies who desire to see the old French quarter of New Orleans. Other features for the ladies have been announced previously.

TRIP TO LEPERS' HOME.

The Board of Control of the Leper Home has invited all members of the Association who may desire to visit this institution. The trip is arranged for Saturday, May 9, and it will take the entire day to make the trip. All desiring to go will leave word at the Bureau of Information. The expense will be nominal, but the exact cost will be furnished on application at the bureau.

OTHER ANNOUNCEMENTS.

The Howard Library, at Lee Circle, through Mr. William Beer, the librarian, invites members of the Association to see some of the special works on medical and hygienic subjects.

The Elks have extended the privileges of their club house to members of the Association who wear their badges.

The river excursion will be on the steamer *New South*, which will accommodate 2,200 people.

The Hotel Committee has received application for rooms for about 2,000 people thus far and 40 or 50 applications are being received daily.

Lunch will be served at reasonable rates in the Washington Artillery Hall by the Christian Women's Exchange.

BANQUETS.

Among the banquet announcements are the following: Section on Nervous and Mental Diseases, at Victor's Restaurant; Sections on Practice of Medicine, Pathology and Physiology, and Materia Medica, Pharmacy and Therapeutics, at West End Hotel; Section on Surgery and Anatomy, a smoker at Young Men's Gymnastic Club; Sections on Cutaneous Medicine and Surgery, and Hygiene and Sanitary Science, a smoker, place to be announced in Section meetings Tuesday afternoon; Section on Laryngology, at Antoine's Restaurant; Section on Ophthalmology, Tulane University Hall, Mr. Emile Lubeigt, chef; Section on Obstetrics and Diseases of Women, same place and menu as Ophthalmology. All these banquets and smokers will be held Tuesday evening.

Notice to Members of the House of Delegates.

The members of the House of Delegates are requested to meet in New Orleans Monday, May 4, at 2 p. m. This meeting will be informal, and no official business can be transacted.

Its purpose is to consider unofficially the business which must be transacted by the House of Delegates and to consider the result of the work of the several committees.

It is believed that this informal meeting on Monday will so fully acquaint the delegates of the work to be done that one meeting each morning will be sufficient to accomplish all the business of the Association. Thus the delegates will be free to attend the afternoon scientific work of the Sections.

Frank Billings, President.

Registration of Members of the House of Delegates.

The Committee on Credentials will be in session Monday morning at the St. Charles Hotel to receive credentials and register all delegates who will present themselves. It is hoped that as many as possible will register during the morning so that there may be no delay when the meeting is called to order at 2 o'clock.

OUR NEW HOME.

THE NEW BUILDING OF THE AMERICAN MEDICAL ASSOCIATION.

The American Medical Association now has a home of its own, and it is paid for. This achievement, the consummation of long-cherished plans, is one of which every member and subscriber may well be proud. The American Medical Association not only owns its own building, but it is thoroughly equipped for printing and publishing The Journal.

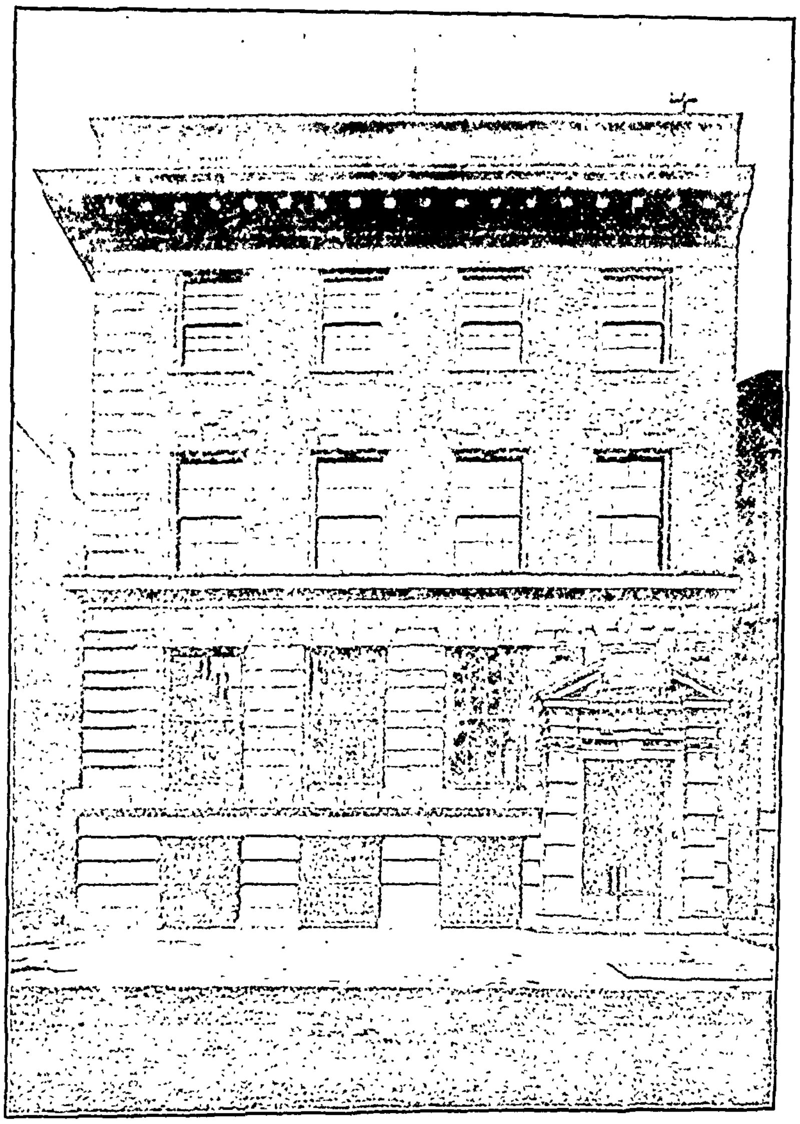
Believing that it will interest our readers to gain a general idea of the building and of the equipment by which The Journal is prepared each week, we give some illustrations showing the interior as well as exterior. The new building is near the corner of Dearborn Avenue and Indiana Street. It is on the north side, a few blocks from the business center of Chicago and not far from the lake. It is 40x80, of three stories with a high basement and is built of brick. The basement is used as a press room, the first floor as folding and mailing departments, the second floor as the editorial and business offices and the third floor as a composing room. The trustees' room and library is also on this floor. The building is strongly built so that it will allow additional stories. The land owned by the Association adjoining the building, on which are three residences, and which is 60x80 feet in size, will admit of addition as soon as the Association requires more room than is at present afforded.

It may not be out of place here to extend an invitation to members, subscribers, advertisers and other friends of the Association to inspect the building and equipment. Many have done so, taking a personal interest in the property. The members realize that they are the actual owners of the building and they have many words of congratulation for the progress that has been made.

One of the illustrations is a chart showing the growth of the circulation of The Journal. It is worthy of study. The following is a statement of the average weekly circulation from the first year to date:

1883	3,800
1884	4,020
1885	4,500
1886	4,800
1887	5,000
1888	5,100
1889	5,450
1890	5,450
1891	5,200
1892	5,200
1893	5,600
1894	6,200
1895	6,548
1896	7,742
1897	9,119
1898	11,270
1899	13,672
1900	17,446
1901	22,049
1902	25,321
1903 (first 4 months)	27,269

It will be remembered that from 1846 to 1882 the proceedings of the Association were published as an annual volume. A change was then made and a weekly journal established in order to give quicker and fuller reports to the members and to serve as a link to bind the members of the Association closer together by more frequent intercourse. The minutes of a meeting held in 1883, at which it was decided to commence publication of The Journal, makes interesting reading. A careful estimate was made to ascertain what support The Journal might receive. It was thought that a revenue from membership and subscriptions of $12,000 could be had; in 1902 the receipts from membership and subscriptions amounted to over $100,000. In 1883 the estimate was made that $5,000 might be received annually from advertising; in 1902 The Journal received about $70,000 from this source. In 1883 $8,000 was estimated to cover the cost of material, printing, wrapping and mailing The Journal; the white paper alone for 1902 cost $36,000.



THE NEW BUILDING OF THE AMERICAN MEDICAL ASSOCIATION.

THE PREVIOUS SESSIONS HELD AT NEW ORLEANS.

The session of the American Medical Association next week in New Orleans will make the third time the Association has met in the Crescent City. The first session was held there May 4-7, 1869, and the second April 28-May 1, 1885. It may not be uninteresting to look back at some things that took place at these sessions.

At the session held in 1869 the President was Dr. W. O. Baldwin of Alabama, and Dr. T. G. Richardson of New Orleans was the chairman of the Committee of Arrangements. The entertainments, according to the report of the meeting, consisted of a reception at the Mechanics' Institute on Tuesday evening, and an excursion down the Mississippi River, "to the plantation of Effingham Lawrence, Esq.," on Friday. One hundred and ninety-one registered at the meeting, beside twenty-seven "Members by invitation." Alabama was represented by 26; Arkansas, 2; Delaware, 1; District of Columbia, 7; Georgia, 3; Illinois, 13; Indiana, 3; Iowa, 1; Kentucky, 14; Louisiana, 21; Michigan, 5; Minnesota, 1; Mississippi, 20; Missouri, 3; New York, 14; Ohio, 13; Pennsylvania, 12; Rhode Island, 2; Tennessee, 13; Texas, 7; West Virginia, 3; Wisconsin, 2; Medical Dept. U. S. Army, 3; Medical Dept. U. S. Navy, 2.

MEDICAL EDUCATION.

As was not unusual at *that time, considerable* interest was shown in medical education, and the efforts at this session, as at many preceding, were for a higher standard. The President's address was mainly devoted to the subject, and it would make interesting reading at the present time. The following preamble and resolutions were introduced and referred to a committee, but the report does not state definitely whether or not the resolutions were adopted:

> Whereas, The medical teachers of America have, after a trial of twenty-two years, failed to meet satisfactorily and efficiently the requirements of the great body of the profession in regard to medical education; and
>
> Whereas, The condition of the profession is yearly becoming more deplorable, on account of the antagonistic and objectionable policy of medical schools, in making the amount of fees charged, rather than a successful teaching, the basis of competition; and

Whereas, To obtain professionally competent graduates, sound and efficient teachers are indispensably necessary; and

Whereas, Such teachers, to be found throughout the country, can not be induced to leave their homes without the assurance of competent remuneration; and

Whereas, Such remuneration can only be obtained by adequate fees charged, unless by a system of low fees the number of students be relied on to make up the inevitable pecuniary deficiency; and

Whereas, Reliance on numbers of students for this purpose deplorably crowds the already overcrowded professional field, diminishing thereby individual income, judgment, experience and skill, thereby compelling practitioners to resort to other avocations as a source of supplemental income, and

Whereas, This devotion to other pursuits often destroys opportunities for study and improvement, degrading thereby the status and standard of American physicians; and

Whereas, The schools of New England, New York, Pennsylvania, Maryland, Virginia, South Carolina, Alabama, Georgia, Texas, Tennessee and District of Columbia now charge comparatively remunerative fees, and

Whereas, The low system of fees is charged in only a few of the middle states, and can with advantage be made to conform to the rate of fees charged elsewhere; and

Whereas, It is as unethical for colleges to underbid each other pecuniarily as for practitioners to do so

DR. ISADORE DYER, NEW ORLEANS, CHAIRMAN OF THE COMMITTEE ON ARRANGEMENTS.

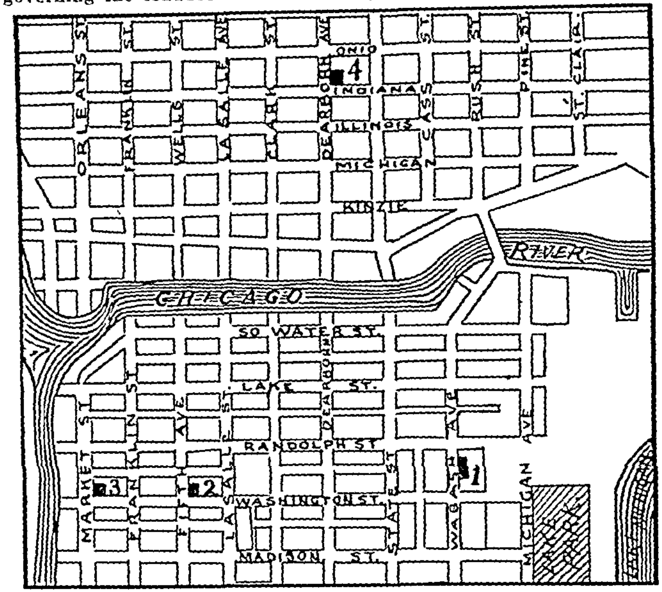
Resolved, That hereafter no medical school in this country, other than those fully endowed, shall be entitled to representation in this Association if the amount charged by such schools for a single course of regular lectures be less than $140.

Resolved, That all schools charging less than this sum are earnestly requested by this Association to advance their rate of fees to the amount mentioned.

Beside the above resolution, the President's Address and other matter referring to medical education was referred to a Committee on Medical Education. This committee made a report, part of which, we think, is worth copying:

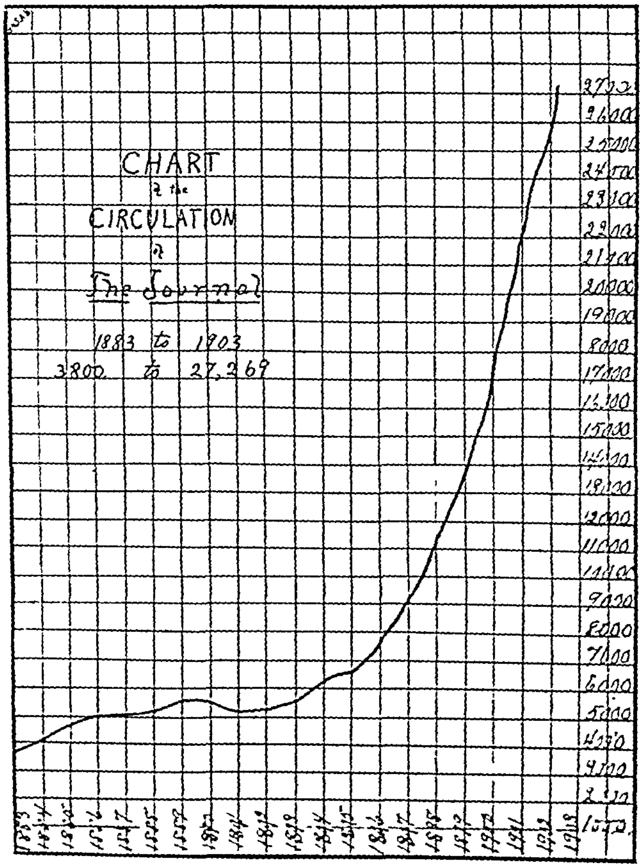
Whereas, The results of all the efforts made during the last twenty-five years to elevate the standard of medical education, through concert of action among the numerous medical colleges of this country, have proved, with equal clearness, that such concert of action in an efficient manner is unattainable; therefore,

Resolved, That whatever is done to establish and maintain a just and fair standard of medical education throughout our whole country must be done by the profession itself, through its own voluntary organizations, in the same manner that it now establishes and enforces its Code of Ethics. The profession is as competent to declare, through its representatives in the national, state and local societies, what shall be the standard of attainments for those to be recognized and admitted into its ranks, and to establish the boards or agencies by which compliance with such standard shall be ascertained, as it is to declare what shall be the ethical rules governing the conduct of those already admitted.



The first place at which the Association owned a part of its printing plant was at 68 Wabash Avenue (1). It was moved to 86 Fifth Avenue (2) in 1894, to 61 Market Street (3) in 1896, and to the present home of The Journal (4), 103 Dearborn Avenue, in 1903.

Resolved, That this Association earnestly requests each state medical society to appoint annually one or more boards of examiners, composed of five thoroughly qualified members, whose duty it shall be to meet at suitable times and places for the examination of all persons, whether graduates of colleges or not, who propose to enter on the practice of medicine in their respective states, except such as have been previously examined and licensed by a similar board in some other state.



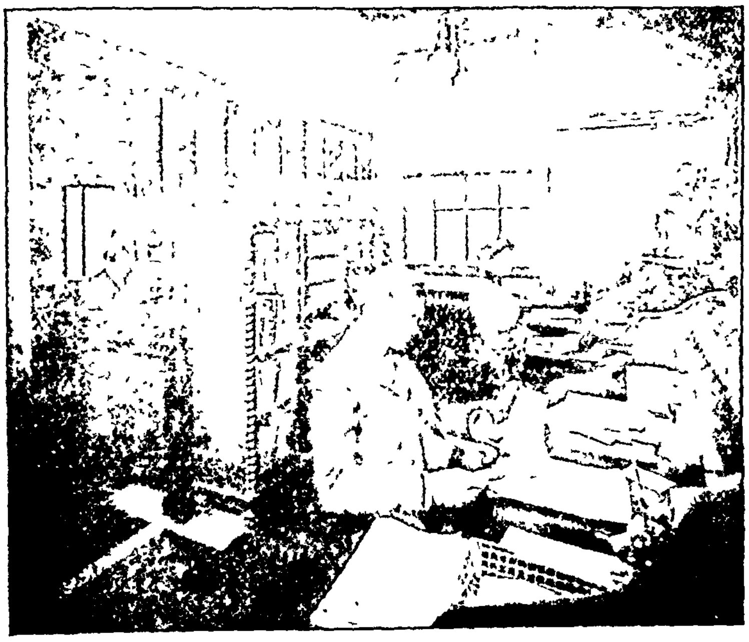
Resolved, That each state medical society be requested to make such regulations concerning the pay of the boards of examiners, and the fee to be charged for a license to practice, that the former shall in no case depend on the amount received from the latter.

Resolved, That each state medical society be requested to require its examining board or boards to exact of every applicant for examination adequate proof that he has a proper general education, is 21 years of age, and has pursued the study of medicine three full years, one year of which time shall have been in some regularly organized medical college, whose curriculum embraces adequate facilities for didactic, demonstrative and hospital clinical instruction.

Resolved, That each state *medical* society be requested to act on the foregoing propositions at the next regular annual meeting after the reception of copies of the same, and, if approved and adopted by the state medical societies of *two thirds* of the states, this Association shall deny representation from all organizations who longer refuse to comply with the same, and shall recommend the state societies to do the *same; and all persons* who, after that date, seek to enter on the practice of medicine without first receiving a license from some state board of examiners, shall be treated ethically as irregular practitioners.

Resolved, That, in adopting the foregoing resolutions, by which it is proposed to treat the medical college *diploma* the same as the diploma of any literary college, *this* Association is actuated by no desire to injure the medical schools of our *country.* On the contrary, by the adoption of the fourth resolution, at the same time that the value of the mere college diploma is practically nullified, it is the desire and confident expectation that those institutions will be greatly benefited, because they will be forced to rival each other in the extent and efficiency of their courses of instruction, instead of the number of diplomas which they can annually distribute.

AN EFFICIENT NATIONAL MEDICAL DIRECTORY.



PART OF THE EDITORIAL ROOMS.

Evidently at that time the need of a national directory of the medical profession was recognized, for Dr. J. H. Packard of Pennsylvania, who was chairman of the committee appointed the previous year to consider the subject, made his report, and the following resolution was adopted:

Resolved, That each state medical society be requested to prepare an annual register of all the regular practitioners of medicine in their respective states, giving the names of the colleges in which they may have graduated, and date of diploma or license.

It is too bad that this has not thus far been carried out. We sincerely hope it will be in the near future.

MEDICAL ORGANIZATION.

Considerable interest was shown in medical organization at that meeting, and it was at that time that an amendment to the By-Laws was adopted making membership in the American Medical Association depend on membership in a local society. The following was added to one of the paragraphs of the By-Laws:

Nor shall any person not a member and supporter of a local medical society, where such a one exists, be eligible to membership in the American Medical Association.

This clause has been in the Constitution and By-Laws ever since, although many think it is a new idea just promulgated in the reorganization work now going on.

THE SESSION OF 1885.

The session of 1885 was held under the presidency of Dr. Henry F. Campbell of Georgia. Dr. Samuel Logan of New Orleans was chairman of the Committee of Arrangements, and delivered the address of welcome.

Considerable interest was shown at this meeting in the meeting of the International Medical Congress, which was held in 1887.

As usual, the Association took some action in regard to elevating the standard of medicine in this country. The following resolutions in regard to the creation of state boards of examiners were adopted:

Resolved, That the Section on State Medicine earnestly advocates the establishment in every state *and* territory of state boards of medical examiners and licensers, whose *certificate* shall be the *only* license permitting practice of medicine in said states.

Resolved, That the Section requests the American Medical Association to direct its Permanent Secretary to transmit a copy of the annexed draft of a bill to the secretary of each and every state medical society, requesting that each state society discuss said bill, and report at the next meeting *of* this Association its views on the desirability of advocating such a bill.

THREE OF THE LINOTYPE MACHINES.

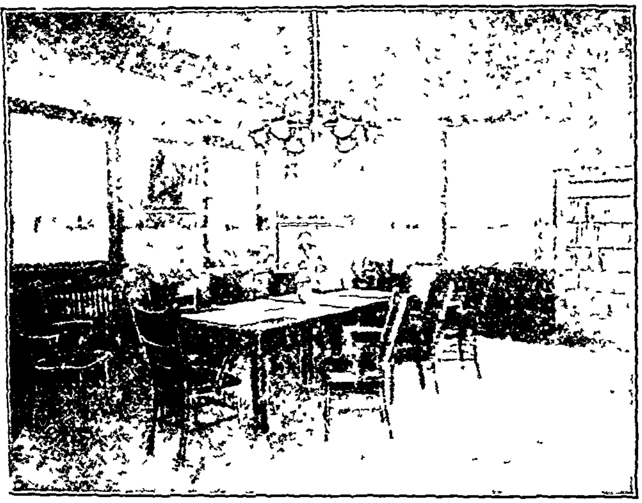
RUSH MONUMENT FUND.

Dr. A. L. Gihon, who, the preceding year, was appointed chairman of the Committee on the Rush Monument Fund, brought in the first report, which is a long one. It is in the form of an argument for the erection of a monument to Benjamin Rush, followed by a consideration of the character of the monument and the probable cost, the latter being estimated at $40,000. The question was asked in the report, "Can the 90,000 physicians in the United States raise $40,000 for such a purpose?" And it was answered: "If every member of the profession were to contribute only 50 cents the question would be solved, but as such unanimity is hardly to be expected, your committee has preferred to estimate that an equal number may decline to assent to their proposition, in which event, from a subscription rate of only $1 apiece, the sum of $45,000 will still accrue and be ample to erect a monument comparable in every respect to the splendid equestrian statues of General Thomas and General Scott or the seated figure of Chief Justice Marshall." The committee closed its report by recommending the adoption of certain resolutions which it had prepared. These, in brief, were that the Association undertake to erect a statue to Dr. Benjamin Rush in the City of Washington; that the necessary funds for this purpose be obtained by subscriptions limited to $1 from each physician and student of medicine in the United States, and by the voluntary donations of such additional sums as may be tendered by persons interested in the work; that a standing committee, to be styled the Rush Monument Committee, be appointed by the President, and the last resolution was:

> *Resolved* That an effort be made to determine a site for the monument, so that the ceremonies of its dedication may be made coincident with the meeting of the International Medical Congress at Washington in 1887

The year 1903 has come and the Rush monument is not yet erected. Each year since that time, until the year preceding his death, Dr. Gihon presented his report and his plea for this monument, as many of our readers know.

The total membership at this time was given as 3,050.



THE TRUSTEES' ROOM.

As intimated in the report of the Board of Trustees, this large increase in two years came about through the establishment of THE JOURNAL.

The officers of the seven Sections of the Association were as follows:

Section on Practice of Medicine, Materia Medica and Physiology: Chairman, J. T. Whittaker, Cincinnati; Secretary, B. L. Coleman, Lexington, Ky.

Section on Obstetrics and Diseases of Women: Chairman, S. C. Gordon, Portland, Me.; Secretary, —— Paine, Texas.

Section on Surgery and Anatomy: Chairman, Nicholas Senn, Milwaukee, Wis.; Secretary, H. H. Mudd, St. Louis.

Section on State Medicine: Chairman, John H. Rauch, Springfield, Ill.; Secretary, F. E. Daniel, Austin, Texas.

Section on Ophthalmology, Otology and Laryngology: Chairman, Eugene Smith, Detroit; Secretary, J. F. Fulton, St. Paul, Minn.

Section on Diseases of Children: Chairman, W. D. Haggard, Nashville, Tenn.; Secretary, W B. Lawrence, Batesville, Ark.

Section on Oral and Dental Surgery: Chairman, John S. Marshall, Chicago; Secretary, A. E. Baldwin, Chicago.

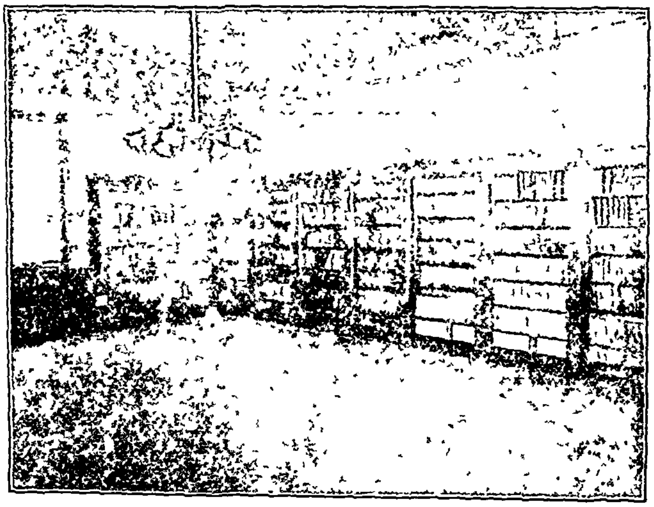
Dr. William Brodie, Detroit, was elected President for the ensuing year.

HOUSE OF DELEGATES.

The House of Delegates will be made up of the following delegates so far as we are advised. Those states not named have not appointed their delegates or have not sent in the names. Several states will be entitled to a larger representation than last year.

Delegates from the State Societies.

Arkansas—J. A. Dibrell, Little Rock.
California—H. Bert Ellis, Los Angeles.
Colorado—C. K. Fleming, Denver
Connecticut—C. S. Rodman, Waterbury; C. E. Brayton, Stonington.
Delaware—George W. Marshall, Milford.
District of Columbia—George M. Kober.
Florida—R. D. Murray, Key West.
Georgia—Jas. B. Morgan, Augusta; Floyd W. McRae, Atlanta.
Indian Territory—B. F. Fortner, Vinita.
Indiana—G. W. Kemper, Muncie; Ewin Walker, Evansville; W. N. Wishard, Indianapolis; D. C Peyton, Jeffersonville.
Iowa—J. R. Guthrie, Dubuque; Samuel Bailey, Mt. Ayr.
Kansas—J. E. Minney, Topeka.
Kentucky—J. N. McCormack, Bowling Green; Ap Morgan Vance, Louisville; I A. Shirley, Winchester.
Louisiana—Rudolph Matas, New Orleans.
Massachusetts—W. N. Swift, New Bedford; A. G. Minshall, Northampton; B. H. Hartwell, Ayer; W. T. Councilman, Boston; J. C. Warren, Boston; H. E. Marion, Brighton.



A CORNER OF THE LIBRARY.

Michigan—H. O. Walker, Detroit; V. C. Vaughan, Ann Arbor; T. A. Felch, Ann Arbor; J. B. Griswold, Grand Rapids.
Minnesota—A. W. Abbott, Minneapolis; Wm. Davis, St. Paul.
Mississippi—J. C. Hall, Anguilla.
Missouri—F. J. Lutz, St. Louis; Jabez N. Jackson, Kansas City; Wm. Dorsett, St. Louis.
Montana—T. J. Murray, Butte.
New Hampshire—Ira J. Prouty, Keene.
New Jersey—Chas. J. Kipp, Newark; Elias J. Marsh, Paterson; L. M. Halsey, Williamstown.
New York—E. Eliot Harris, New York; Charles A. Wall, Buffalo; Elias Lester, Seneca Falls; Jos. D. Bryant, New York.
North Carolina—E. C. Laird, Hot Springs; E. B. Glenn, Asheville.
Oklahoma—
Oregon—Andrew C. Smith, Portland.
Pennsylvania—William T. Bishop, Harrisburg; H. S. McConnel, New Brighton; John B. Roberts, Philadelphia; Wm. M. Welch, Philadelphia; Wm. S. Foster, Pittsburg; Geo. W. Guthrie, Wilkesbarre; G. C. Harman, Huntingdon; C. L. Stevens, Athens.
Rhode Island—John Champlin, Westerly; Frederick T. Rogers, Providence.
South Dakota—J. L. Stewart, Irene.
Tennessee—Daniel E. Nelson, Chattanooga; Louis LeRoy, Nashville.
Texas—H. A. West, Galveston.
Vermont—D. C. Hawley, Burlington.

Virginia—J. R. Gildersleeve, Tazewell; Stuart McGuire, Richmond; R. S. Martin, Stuart.

Washington—Park W. Willis, Seattle.

West Virginia—L. D. Wilson, Wheeling.

Wisconsin—W. T. Sarles, Sparta; H. Reineking, Sheboygan.

Wyoming—E. E. Levers, Spring Valley.

U. S. P. H. and M.-H. S.—Walter Wyman, Washington, D.C.

Delegates from the Sections.

Practice of Medicine—J. M. Anders, Philadelphia; C. G. Stockton, Buffalo.

Surgery and Anatomy—W. L. Rodman, Philadelphia; Robert F. Weir, New York.

Obstetrics and Diseases of Women—Edwin Ricketts, Cincinnati; E. E. Montgomery, Philadelphia.

Hygiene and Sanitary Science—N. S. Davis, Jr., Chicago; A. R. Reynolds, Chicago.

BUSINESS AND EDITORIAL OFFICES.

Ophthalmology—J. A. Lippincott, Pittsburg, Pa.; Frank Allport, Chicago.

Diseases of Children—A. C. Cotton, Chicago; S. W. Kelley, Cleveland, Ohio.

Stomatology—G. V. I. Brown, Milwaukee, Wis.; A. E. Baldwin, Chicago.

Nervous and Mental Diseases—H. N. Moyer, Chicago; Richard Dewey, Wauwatosa, Wis.

Cutaneous Medicine and Surgery—M. B. Hartzell, Philadelphia; W. L. Baum, Chicago.

Laryngology and Otology—Emil Mayer, New York; Norval H. Pearce, Chicago.

Materia Medica, Etc.—O. T. Osborne, New Haven, Conn.; W. B. Hill, Milwaukee, Wis.

Pathology and Physiology—E. R. LeCount, Chicago; J. T. Howard, Jr., Cleveland, Ohio.

SECTION OFFICERS.

We take pleasure in presenting this week half-tone reproductions of the photographs of the officers of the various sections. The success of the Association, as a scientific organization, depends on the manner in which these gentlemen perform their duties, and we believe that the work in the sections of the coming session will show that each of them has lived up to the example of his predecessor. They are deserving of the space allotted to them in this issue of The Journal.

Seven of the sections wisely re-elected their secretaries at Saratoga, namely: Pathology and Physiology, Joseph McFarland, Philadelphia; Obstetrics and Diseases of Women, C. L. Bonifield, Cincinnati, Ohio; Stomatology, Eugene S. Talbot, Chicago; Nervous and Mental Diseases, F. Savary Pearce, Philadelphia; Cutaneous Medicine and Surgery, R. R. Campbell, Chicago; Laryngology and Otology, J. F. Barnhill, Indianapolis, Ind.; Materia Medica, Pharmacy and Therapeutics, C. S. N. Hallberg, Chicago.

PROPOSED CODE OF ETHICS.

Offered at Saratoga Springs, 1902, and to Be Acted on at New Orleans.

At the last session of the American Medical Association the following action was taken:

Dr. E. Eliot Harris, New York, presented the following resolution:

> For more than a year some of the members of the Council of the New York State Medical Association have been engaged in a critical examination of the ethical part of the laws of the American Medical Association, resulting in the preparation of a revision of the

Code of Medical Ethics This revision has been approved by the Council of the New York State Medical Association, and the delegates have been instructed to present it to the House of Delegates at this session

Resolved, That the President appoint a committee of five to examine and report for final action at the annual session in 1903 the proposed revised Code of Medical Ethics which is herewith submitted in writing,

Resolved, That the proposed revised Code of Medical Ethics be published in the Association's JOURNAL three times before the meeting in 1903

On motion of Dr. C A L Reed, Cincinnati, the resolution was adopted

The following constitute the committee: Dr E Eliot Harris, New York, chairman; Dr William H Welch, Baltimore; Dr. T. J. Happel, Tennessee; Dr. Nicholas Senn, Chicago, and Dr. Joseph D Bryant, New York.

fidential intercourse to which physicians are admitted, in their professional visits, should be guarded with the most scrupulous fidelity and honor

SEC 3—The obligation of secrecy extends beyond the period of professional services, none of the privacies of individual or domestic life, no infirmity of disposition or flaw of character observed during medical attendance should ever be divulged by physicians, except when imperatively required to do so by the laws of the state The force of the obligation of secrecy is so great that physicians have been protected in its observance by courts of justice

SEC 4—Frequent visits to the sick are generally requisite, since they enable the physician to arrive at a more perfect knowledge of the disease, and to meet promptly every change which may occur. But unnecessary visits are to be avoided, as they give undue anxiety to the patient

SEC 5—Ordinarily, the physician should not be forward to make gloomy prognostications, but should not fail, on proper occasions, to give to the friends of the patient timely notice of danger when it really exists, and even to the patient, if absolutely necessary This notice, however, is often so peculiarly alarming when given by the physician, that its deliverance ought to be declined whenever it can be assigned to any other person of good judgment.

COMPOSING ROOM

CHAPTER I—OF THE DUTIES OF PHYSICIANS TO THEIR PATIENTS AND OF THE OBLIGATIONS OF PATIENTS TO THEIR PHYSICIANS

ARTICLE I—DUTIES OF PHYSICIANS TO THEIR PATIENTS

SECTION 1—Physicians should not only be ever ready to obey the calls of the sick, but should be mindful of the high character of their mission and of the responsibility they must incur in the discharge of momentous duties In their ministrations they should never forget that the ease, the health, and the lives of those entrusted to their care depend on skill, attention, and fidelity In their deportment they should unite tenderness, cheerfulness and firmness, and thus inspire all sufferers with gratitude, respect and confidence These observances are the more sacred because, generally, the only tribunal to adjudge penalties for carelessness or neglect is their own conscience.

SEC 2—Every case committed to the charge of a physician should be treated with attention and humanity, and reasonable indulgence should be granted to the caprices of the sick. Secrecy and delicacy should be strictly observed, and the familiar and con

SEC 6—The physician should be the minister of hope and comfort to the sick, since life may be lengthened or shortened not only by the acts but by the words or manner of the physician whose solemn duty is to avoid all utterances and actions having a tendency to discourage and depress the patient.

SEC 7—The medical attendant ought not to abandon a patient because deemed incurable; for, continued attention may be highly useful to the sufferer, and comforting to the relatives, even in the last period of the fatal malady, by alleviating pain and by soothing mental anguish

SEC 8—The opportunity which a physician has of promoting and strengthening the good resolutions of patients suffering under the consequences of vicious conduct ought never to be neglected. Good counsels, or even remonstrances, will give satisfaction, not offense, if they be [illegible] proffered [illegible] a gent[illegible] of virtue, accompanied by a sincere interest in the welfare of the person to whom they are addressed.

ARTICLE II.—OBLIGATIONS OF PATIENTS TO THEIR PHYSICIANS.

SECTION 1.—The members of the medical profession, on whom is enjoined the performance of so many important and arduous duties toward the community, and who are required to make so many sacrifices of comfort, ease, and health, for the welfare of those who avail themselves of their services, are surely entitled to the highest private and public recognition.

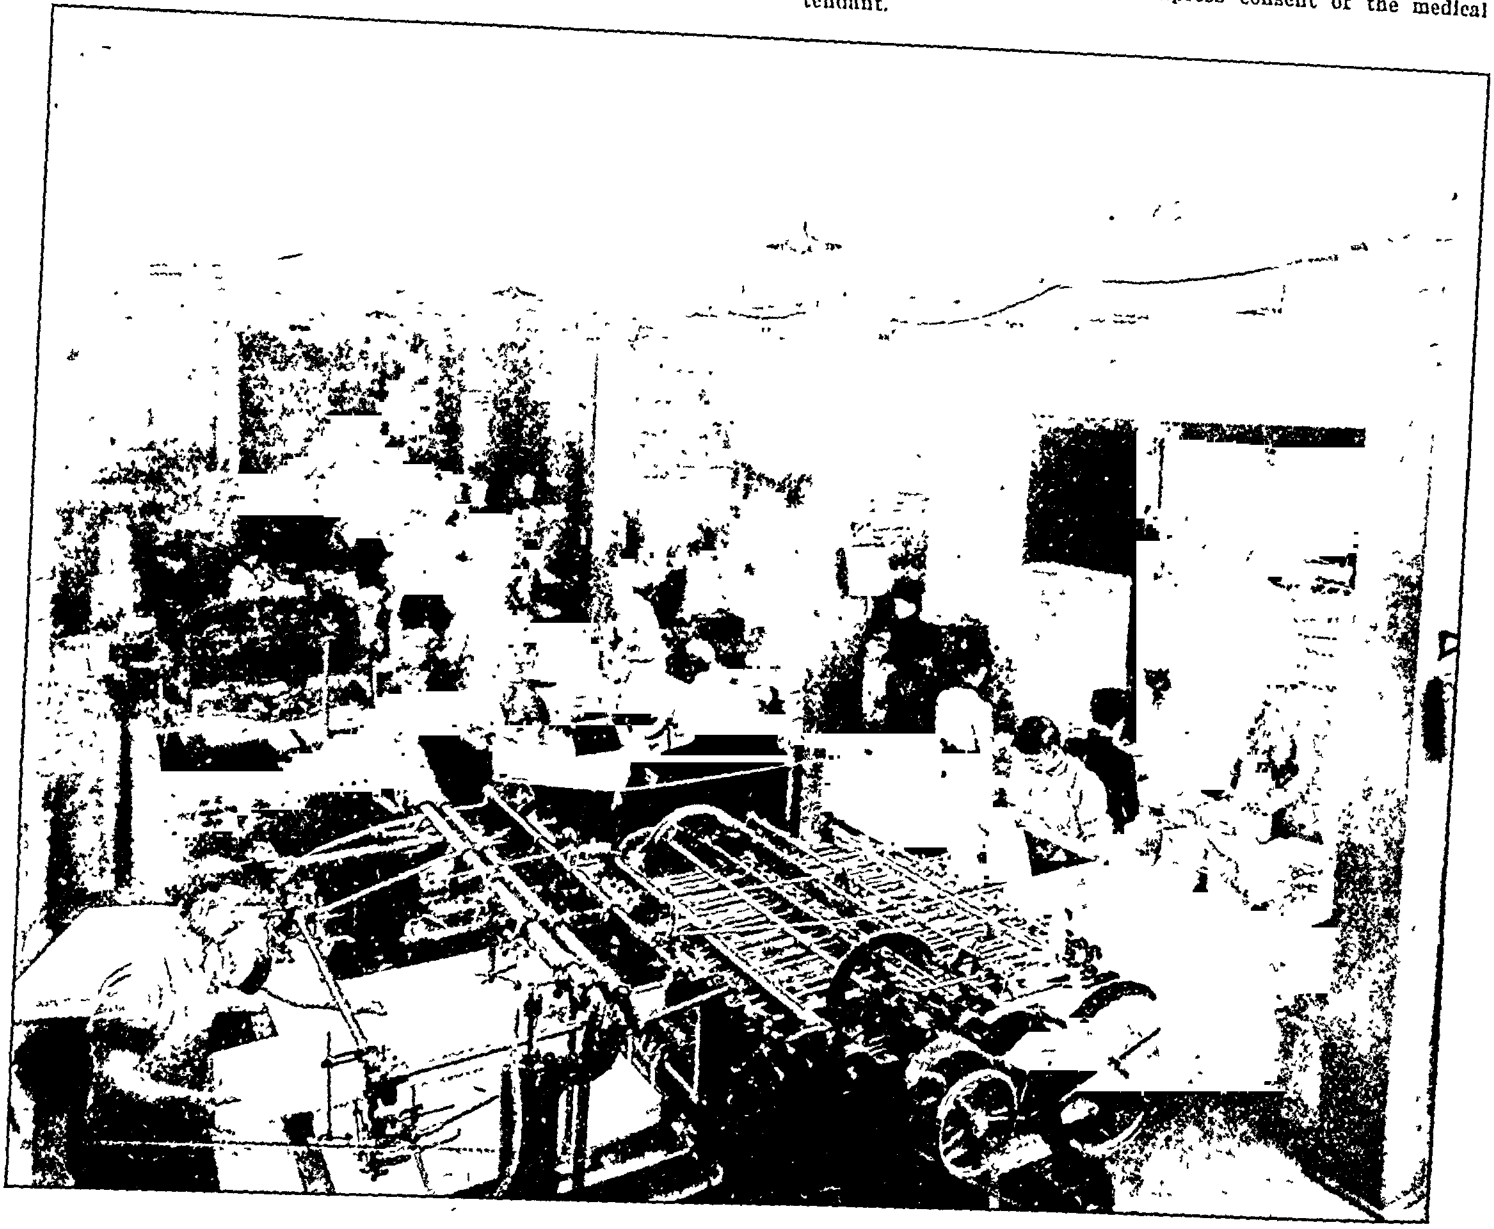
SEC. 2.—The first duty of a patient is to select as medical adviser one who has received a sound general and special education, whose habits are good, and who is not devoted to any pursuit incompatible with professional obligations.

SEC. 3.—The sick should always apply for advice in what may appear to be a trivial case, for the slightest accident may result gravely. It is also important that the patient seek assistance in the forming stage of a violent disease and communicate unreservedly to the physician its supposed cause.

SEC. 8.—Patients should never allow themselves to be persuaded to take any medicine whatever that may be recommended to them by the self-constituted doctors who are so frequently met with and who pretend to possess infallible remedies for every disease. Howsoever simple some of their prescriptions may appear to be, it often happens that, besides being in themselves injurious, they are productive of much mischief by contravening the plan of treatment adopted by the physician in attendance.

SEC. 9.—Whenever possible, the patient should avoid even friendly visits of a physician who is not the regular attendant. But when such visits are received, there should be no conversation on the subject of the patient's disease, as a word may be spoken, without any intention of interference, which may destroy confidence in the course pursued and induce the patient to neglect the prescribed directions.

SEC. 10.—The patient or relatives should never send for a consulting physician without the express consent of the medical attendant.



BINDERY AND MAILING ROOM.

SEC. 4.—The patient should be on friendly terms with the medical adviser and bear in mind that physicians are under the strongest obligations of secrecy.

SEC. 5.—Women should never allow feelings of delicacy to prevent their disclosing the seat of their peculiar complaints. Howsoever commendable a modest reserve may be in the common occurrences of life, its strict observance in medicine is often attended with serious consequences, and a patient may sink under a painful disease which might have been prevented had timely intimation been given to the physician.

SEC. 6.—The obedience of a patient to the directions of the physician should be prompt and implicit. Failure in one particular may render an otherwise judicious treatment dangerous and even fatal. This remark is equally applicable to the unauthorized renewal of prescriptions, and to diet, drink, raiment and exercise.

SEC. 7.—As patients become convalescent they are apt to suppose that the rules prescribed for them may be disregarded, and the consequence, but too often, is a relapse of the disease.

SEC. 11.—Patients should, whenever practicable, send for their physicians in the morning, before the usual hour for going out, and this gives them the opportunity to so apportion their time as to prevent interference of engagements.

SEC. 12.—Except in emergencies patients should avoid calling on their medical advisers during the hours devoted to meals or sleep.

SEC. 13.—The sick should be always in readiness to receive the visits of the physician, as detention, even for a very short time, is often of serious import to some other sufferer.

CHAPTER II.—OF THE DUTIES OF PHYSICIANS TO EACH OTHER AND TO THE PROFESSION AT LARGE.

ARTICLE I.—DUTIES FOR THE SUPPORT OF PROFESSIONAL CHARACTER.

SECTION 1.—Every individual on entering the profession, and thereby becoming entitled to all its privileges and immunities, incurs an obligation to maintain its dignity and honor, to exalt its standing and to extend the bounds of its usefulness.

Sec. 2.—The physician should observe strictly such laws as are instituted for the government of the members of the profession; should honor the fraternity as a body; and, by unwearied diligence, should resort to every honorable means of enriching the science, and, at the same time, entertain a due respect for those seniors who, by their labors, have contributed to its advancement.

Sec. 3.—There is no profession from the members of which greater purity of character and a higher standard of moral excellence are required than the medical; and to attain such eminence is a duty every physician owes alike to the profession and to patients. It is due to these, as without it their respect and confidence can not be commanded; and to the profession because no scientific attainments can compensate for the want of correct moral principles.

Sec. 4.—It is incumbent on physicians to be temperate in all things, for the practice of medicine requires the unremitting exercise of a clear and vigorous understanding; and in emergencies—for which no physician should be unprepared—a steady hand, an acute eye, and an unclouded mind are essential to the welfare, and even to the life, of a human being.

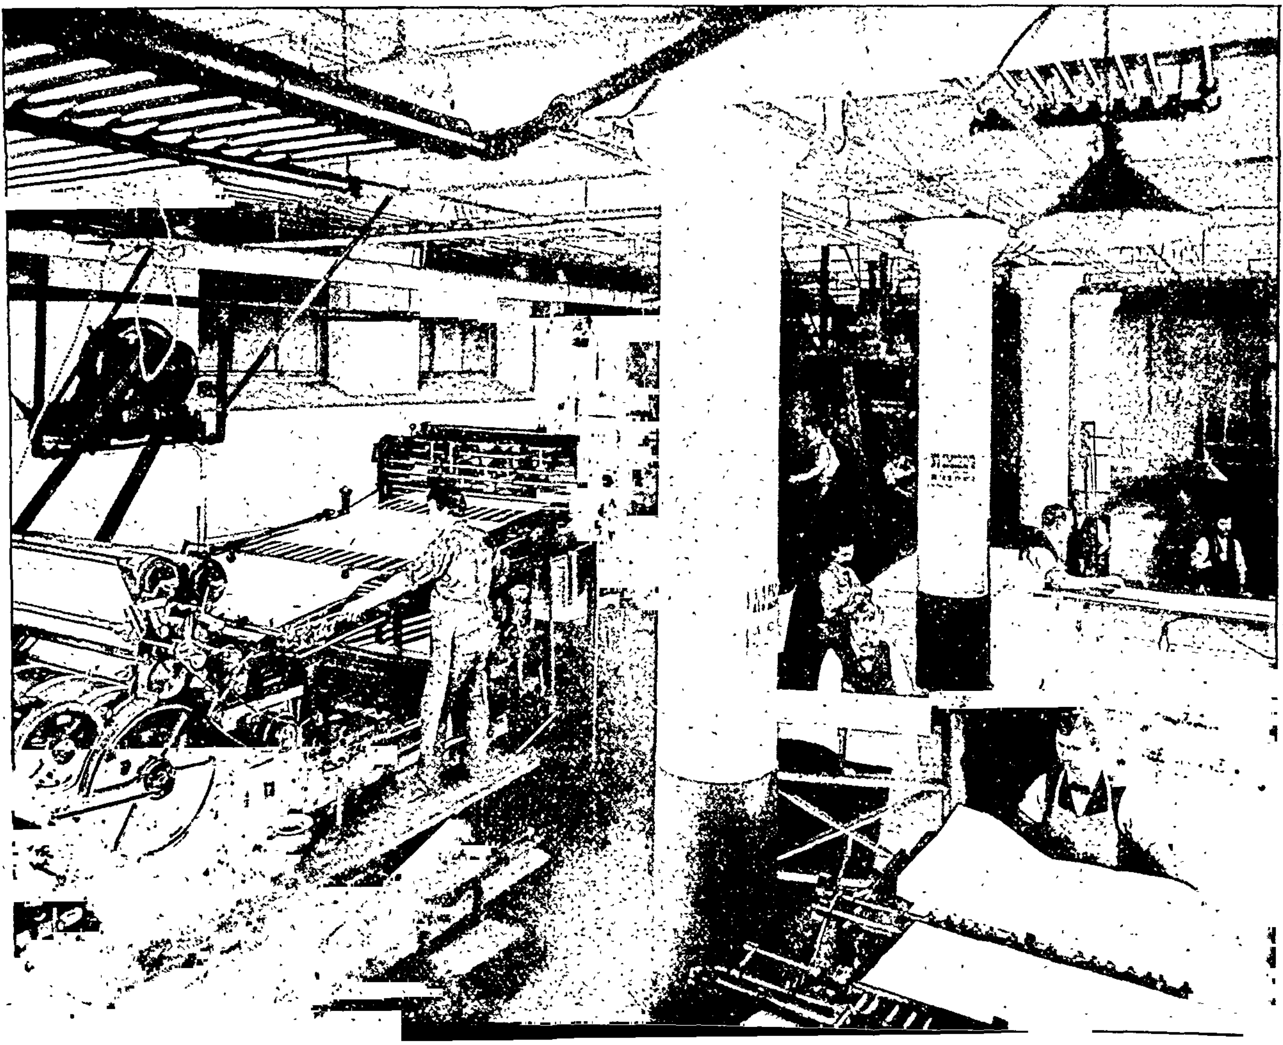
Sec. 5.—It is derogatory to the dignity of the profession to resort to public advertisements or private cards inviting the attention of persons affected with particular diseases, offering advice and medicine gratis and promising radical cures; or to publish cases and operations in the daily prints, or to suffer such publications to be made; to invite laymen (other than relatives who may desire to be at hand) to be present at operations; to boast of cures and remedies; to adduce certificates of skill and success; or to employ any of the other methods of charlatans.

Sec. 6.—Equally derogatory to professional character it is for a physician to hold a patent for any surgical instrument or medicine; or to dispense, or promote the use of, a secret medicine, whether it be composed by this physician or the exclusive property of others, for if such nostrum be of real efficacy, any concealment regarding it is inconsistent with beneficence and professional liberality, and if mystery alone give it public notoriety, such craft implies either disgraceful ignorance or fraudulent avarice. It is highly reprehensible for physicians to give certificates attesting the efficacy of secret medicines, or of any of the other substances that may be used medicinally.

ARTICLE II.—PROFESSIONAL SERVICES OF PHYSICIANS TO EACH OTHER.

Section 1.—All practicing physicians and their immediate dependents are entitled to the gratuitous services of any one or more of the physicians residing near them.

Sec. 2.—Physicians afflicted with disease should not, as a general rule, undertake the treatment of their own sickness, nor of that of members of their family, for obvious reasons. In such circumstances they are peculiarly dependent on each other; therefore, kind offices and professional aid should always be cheerfully and gratuitously afforded. Visits ought not, however, to be obtruded officiously, as such civility may give rise to embarrassment or interfere with that choice on which confidence depends.



PRESS ROOM.

Sec. 3.—When a physician is summoned, from a distance, to the bedside of a colleague in easy financial circumstances, a compensation, proportionate to traveling expenses and to the pecuniary loss entailed by absence from the accustomed field of professional labor, should be made by the patient or relatives.

ARTICLE III.—OF THE DUTIES OF PHYSICIANS AS RESPECTS VICARIOUS OFFICES.

Section 1.—The affairs of life, the pursuit of health and the various accidents and contingencies to which a physician is peculiarly exposed sometimes require the temporary withdrawal of this physician from daily professional labor and the appointment of a colleague to act for a specified time.

Sec. 2.—The colleague's compliance is an act of courtesy which should always be performed with the utmost consideration for the interest and character of the family physician, and when exercised for a short period half of the pecuniary obligations for such services should be awarded to the acting physician.

ARTICLE IV.—OF THE DUTIES OF PHYSICIANS IN REGARD TO CONSULTATIONS.

SECTION 1.—The broadest dictates of humanity should be obeyed by physicians whenever and wherever their services are needed to meet emergencies occasioned by disease or accident.

SEC. 2.—The good of the patient being the sole object in view, any physician having a license to practice medicine conferred by a medical board authorized by the state may be aided in consultation.

SEC. 3.—No physician who indicates to the public that his practice is based on a sectarian system of medicine shall be entitled to professional fellowship or to recognition in medical bodies.

SEC. 4.—Consultations should be promoted in difficult cases, as they give rise to confidence and more enlarged views in practice.

Dr. W. S. Thayer, Baltimore, Chairman of the Section on Practice of Medicine.

SEC. 5.—The utmost punctuality should be observed in the visits of physicians when they are to hold consultations, and this is generally practicable, for society has been so considerate as to allow the plea of a professional engagement to take precedence over all others and to be a good reason for the relinquishment of any present occupation.

SEC. 6.—As professional engagements may sometimes interfere and delay one of the parties, the physician who first arrives should wait for a reasonable time, after which the consultation should be considered as postponed to a new appointment.

SEC. 7.—In consultations no rivalship or jealousy should be indulged; candor, probity and all due respect should be observed toward the physician in charge of the case.

SEC. 8.—The attending physician should be the first to question the sick, after which the consultant should have the opportunity to make such further inquiries as may be necessary.

SEC. 9.—After due examination of the patient, both physicians should retire to a private place for deliberation; and the one first in attendance should communicate the directions, agreed on, to the patient or friends, as well as any opinion which it may be thought proper to express.

SEC. 10.—No statement or discussion of the case should take place before the patient or friends, except in the presence of all the physicians attending, and by their common consent; and no opinions or prognostications should be delivered which are not the result of previous deliberation and concurrence.

SEC. 11.—The opinion of the physician in attendance should be delivered first to the patient or friends; and when there are several consultants they should deliver their opinions in the order in which they have been called.

SEC. 12.—No decision should restrain the attending physician from making such variations in the mode of treatment as any subsequent unexpected change in the character of the case may demand. But at the next consultation reasons for the variations should be stated. The same privilege, with its obligation, belongs to the consultant when sent for in an emergency during the absence of the family physician.

SEC. 13.—The attending physician, at any time, may prescribe for the patient; not so the consultant, when alone, except in a case of emergency or when called from a considerable distance. In case of emergency the consultant should do what is needed, and in the other case should do no more than make an examination of the patient and leave a written opinion, under seal, to be delivered to the attending physician.

SEC. 14.—In consultations theoretical discussions should be avoided, as occasioning perplexity and loss of time. For there may be much diversity of opinion concerning speculative points, with perfect agreement in those modes of practice which are founded not on hypothesis, but on experience and observation.

SEC. 15.—All discussions in consultation should be held as confidential. Neither by words nor manner should any of the parties to a consultation assert or intimate that any part of the treatment pursued did not receive his assent.

SEC. 16.—Should an irreconcilable diversity of opinion occur when several physicians are called on in consultation, the opinion of the majority should be considered as decisive; but if the numbers be equal on each side, then the decision should rest with the attending physician.

SEC. 17.—It may happen that two physicians can not agree in their views of the nature of a case and of the treatment to be pursued. In the event of such disagreement a third physician should, if practicable, be called in and, if circumstances prevent the adoption of this course, the patient or friends should make the selection. The physician so designated should take charge of the case and the other should then gracefully retire from any further deliberation in the consultation, or participation in the management of the case.

Dr. James B McElroy, Stovall, Miss., Secretary of the Section on Practice of Medicine

SEC. 18.—As circumstances sometimes arise to render a special consultation desirable, when the continued attendance of two physicians might be objectionable to the patient, the physician whose assistance is required in such cases should sedulously guard against all future, unsolicited attendance. Such consultations requiring an extraordinary portion of time and attention, at least a double fee should be expected.

SEC. 19.—A physician who is called in consultation should observe the most honorable and scrupulous regard for the character and standing of the attending physician, whose conduct of the case should be justified as far as can be, consistently with a conscientious regard for truth, and no hint or insinuation should be thrown out which could impair the confidence reposed in the attending physician.

ARTICLE V.—DUTIES OF PHYSICIANS IN CASES OF INTERFERENCE.

SECTION 1.—Medicine being a liberal profession, those admitted to its ranks should found their expectations of practice entirely on the extent of their medical education.

SEC. 2.—The physician, in his intercourse with a patient under the care of another physician, should observe the strictest caution and reserve; should give no disingenuous hints relative to the nature and treatment of the patient's disorder, nor should the course of conduct of this physician directly or indirectly tend to diminish the trust reposed in the attending physician.

Dr A. Palmer Dudley, New York, Chairman of the Section on Obstetrics and Diseases of Women.

SEC. 3.—The same circumspection should be observed when, from motives of business or friendship, a physician is prompted to visit a person who is under the direction of another physician. Indeed, such visits should be avoided, except under peculiar circumstances, and when they are made, no particular inquiries should be instituted relative to the nature of the disease, or the remedies employed, but the topics of conversation should be as foreign to the case as circumstances will admit.

SEC. 4.—A physician ought not to take charge of, or prescribe for, a patient who has recently been under the care of another physician in the same illness, except in case of a sudden emergency, or in consultation with the physician previously in attendance, or when that physician has relinquished the case or has been dismissed in due form.

SEC. 5.—Placed in the position stated in the preceding section, the physician should never throw out damaging insinuations on the practice previously adopted, and, indeed, should justify it if consistent with truth and probity; for it often happens that patients become dissatisfied when they are not immediately relieved, and, as many diseases are naturally protracted, the seeming want of success, in the first stage of treatment, affords no evidence of a lack of knowledge or skill.

SEC. 6.—When a physician is called to an urgent case, because the family attendant is not at hand, unless assistance in consultation is desired, this physician should resign the care of the patient immediately on the arrival of the family physician.

SEC. 7.—It often happens, in cases of sudden illness, or of accidents and injuries, owing to the alarm and anxiety of friends, that several physicians are simultaneously summoned. Under these circumstances, courtesy should assign the patient to the first who arrives and who, if necessary, may invoke the aid of some of those present. In such a case, however, the acting physician should cause the family physician to be called, and should withdraw unless requested to continue in attendance.

SEC. 8.—Whenever a physician is called to the patient of another physician during the enforced absence of that physician the case should be surrendered on the return of the absentee.

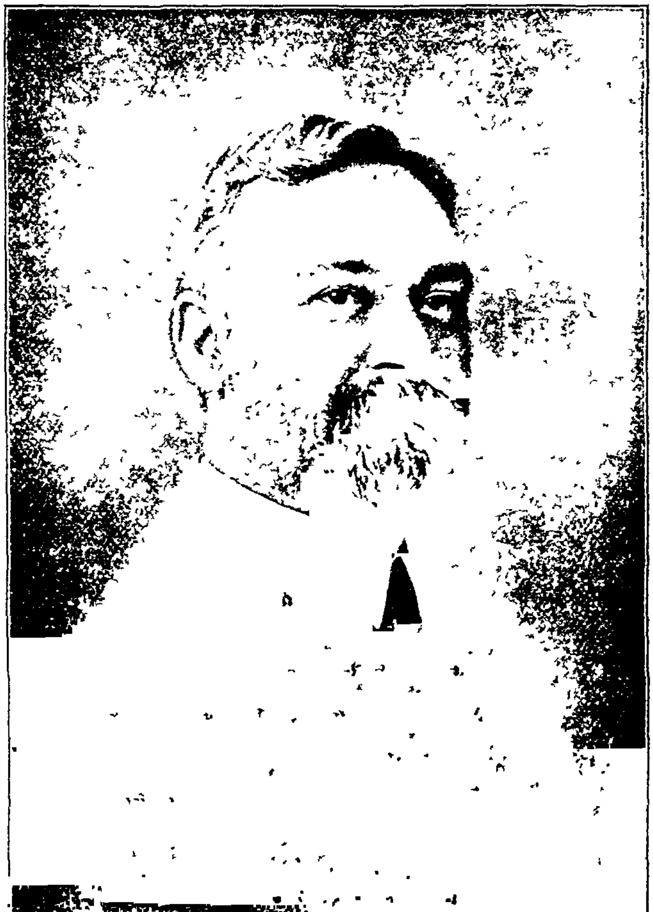
SEC. 9.—A physician, while visiting a sick person in the country, may be asked to see another physician's patient in consequence of a sudden aggravation of the disease. On such an occasion the immediate needs of the patient should be attended to and the case relinquished on the arrival of the attending physician.

SEC. 10.—When a physician who has been engaged to attend an obstetric case is absent and another is sent for, delivery being accomplished during the vicarious attendance, the acting physician is entitled to half the fee, but must resign the patient on the arrival of the physician first engaged.

ARTICLE VI.—OF DIFFERENCES BETWEEN PHYSICIANS.

SECTION 1.—Diversity of opinion and opposition of interest may, in the medical as in other professions, sometimes occasion controversy and even contention. Whenever such cases unfortunately occur and can not be immediately terminated, they should be referred to the arbitration of a sufficient number of physicians or a court-medical.

SEC. 2.—A peculiar reserve must be maintained by physicians toward the public in regard to some professional questions, and as there exist many points in medical ethics and etiquette through which the feelings of physicians may be painfully assailed in their intercourse, and which can not be understood or appreciated by general society, neither the subject-matter of their differences nor the adjudication of the arbitrators should be made public.



Dr. C. L. Bonifield, Cincinnati, Secretary of the Section on Obstetrics and Diseases of Women.

ARTICLE VII.—OF PECUNIARY ACKNOWLEDGMENT.

SECTION 1.—There is no profession by the members of which eleemosynary services are more liberally dispensed than the medical, but justice requires that some limits should be placed to their performance.

Sec. 2.—Poverty, mutual professional obligations, and certain of the public duties named in Sections 1 and 2 of Article 1, of Chapter III, should always be recognized as presenting valid claims for gratuitous services; but neither institutions endowed by the public or by the rich, or by societies for mutual benefit, for life insurance, or for analogous purposes, or any profession or occupation, can be admitted to possess such privilege.

Sec. 3.—It can not be justly expected of physicians to furnish certificates of inability to serve on juries, or to perform militia duty; or to testify to the state of health of persons wishing to insure their lives, obtain pensions, or the like, without a pecuniary acknowledgment. But to persons in indigent circumstances such services should always be cheerfully and freely accorded.

Dr. James E. Moore, Minneapolis, Chairman of Section on Surgery and Anatomy.

Sec. 4.—Some general rules should be adopted by the physicians in every town or district relative to the minimum pecuniary acknowledgment from their patients; and it should be deemed a point of honor to adhere to these rules with as much uniformity as varying circumstances will admit.

Sec. 5.—It is derogatory to professional character for physicians to pay or to offer to pay commissions to any person whatsoever who may recommend to them patients requiring general or special treatment or surgical operations. It is equally derogatory to professional character for physicians to demand or to receive such commissions.

Chapter III.—Of the Duties of the Profession to the Public and of the Obligations of the Public to the Profession.

Article I.—Duties of the Profession to the Public.

Section 1.—As good citizens it is the duty of physicians to be very vigilant for the welfare of the community, and to bear their part in sustaining its institutions and burdens; they should also be ever ready to give counsel to the public in relation to subjects especially appertaining to their profession, as on questions of sanitary police, public hygiene and legal medicine.

Sec. 2.—It is the province of physicians to enlighten the public in regard to quarantine regulations; to the location, arrangement, and dietaries of hospitals, asylums, schools, prisons and similar institutions; in relation to the sanitary police of towns, as drainage, ventilation, etc.; and in regard to measures for the prevention of epidemic and contagious diseases; and when pestilence prevails, it is their duty to face the danger, and to continue their labors for the alleviation of the suffering people, even at the risk of their own lives.

Sec. 3.—Physicians, when called on by legally constituted authorities, should always be ready to enlighten inquests and courts of justice on subjects strictly medical, such as involve questions relating to sanity, legitimacy, murder by poison or other violent means, and various other subjects embraced in the science of medical jurisprudence. It is but just, however, for them to expect due compensation for their services.

Sec. 4.—It is the duty of physicians, who are frequent witnesses of the great wrongs committed by charlatans, and of the injury to health and even destruction of life caused by the use of their treatment, to enlighten the public on these subjects, and to make known the injuries sustained by the unwary from the devices and pretensions of these artful impostors.

Sec. 5.—Physicians ought to use all the influence which they possess to discourage pharmacists from vending the secret or other medicines of charlatans, or from being in any way engaged in their manufacture.

Article II.—Obligations of the Public to Physicians.

Section 1.—The benefits accruing to the public, directly and indirectly, from the unwearied labors of the profession, are so numerous and important that physicians are entitled to the utmost consideration and respect from the community.

Sec. 2.—The public ought to entertain a just appreciation of medical qualifications; to make a proper discrimination between true science and the assumptions of ignorance and charlatanism; and to afford every encouragement and facility for the acquisition of thorough medical education.

Book Notices.

A System of Clinical Medicine, Dealing with the Diagnosis, Prognosis and Treatment of Disease for Students and Practitioners.

Dr. John C. Munro, Boston, Secretary of the Section on Surgery and Anatomy

By Thomas D Savill, M D Lond, Physician to the West End Hospital for Diseases of the Nervous System. Volume I. Local Diseases and Microbic Disorders Cloth Pp. 702. Price, $4 38 net. London: J & A Churchill Philadelphia: P Blakiston's Son & Co 1903

This is a treatise on practice on a somewhat novel plan. The author has endeavored to bring in modern methods and in this work he follows up the inductive method of going from particulars to generalities, leading up through the symptoms to the diagnosis. Each chapter is divided into three parts, one treating of the symptoms which may indicate disease of the organism or region under discussion, the errors which may be made and the causes which give rise to them. The second part treats of the physical signs of disease in the region and the methods used to elicit them. The third and the largest portion begins with the clinical signs of the various maladies affecting that region and a summary of the routine procedure to be adopted, followed by sections dealing with several diseases arranged according to their clinical relationships; for example, quoting the author in his introduction, in chapter 3 on the heart, "part A describes and differentiates the various causes of breathlessness, palpitation, precordial pain and other symptoms which may be indicative of heart disease. Part B describes percussion, auscultation and other methods of examining the heart and part C deals seriatim first with acute and secondly with chronic disturbances classified and arranged on a clinical basis." With this explanation the general plan of the work can be readily appreciated. There are certain special features, however, which call for notice. One is the emphasis given to salient features of disease in italicized paragraphs at the head of each section treating of a separate malady. Another is a list of formulas at the close of the work as well as the description of other therapeutic methods, such as the general treatment of fever, etc., and the description of the exercises according to the Nauheim method for cardiac diseases. The book is not a complete treatise on the practice of medicine, dealing as it does only with the so-called local diseases and those diseases causing local symptoms and specific fevers of microbic origin. It is, however, complete in itself. There are one or two points in which the book is not up to date; the author, for example, states in his note on yellow fever that it is conveyed by fomites, ignoring the recent striking researches on the subject and the mosquito theory of the transmission altogether. On the whole, the book can not fail to prove a useful one.

Dr. H. M. Bracken, Minneapolis, Chairman of the Section on Hygiene and Sanitary Science.

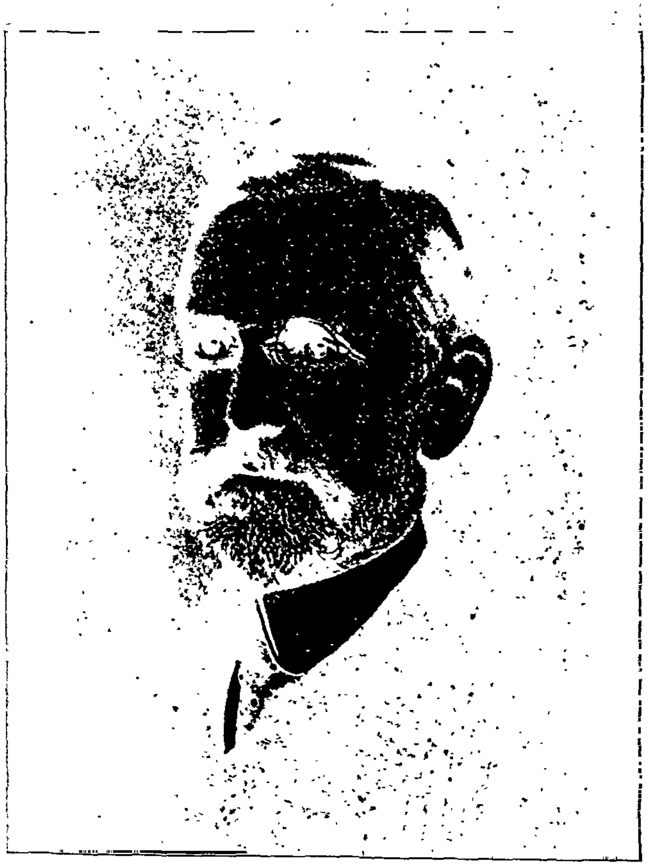
Clinical Surgery for the Instruction of Practitioners and Students of Surgery. By A. J. Ochsner, B.S., F.R.M.S., M.D., Chicago, Surgeon-in-Chief, Augustana Hospital and St. Mary's Hospital. Pp. 481. Price: Cloth, $6.00; Leather, $7.00. Chicago: Cleveland Press (The Clinical Review Publishing Co.).

The author says in the preface that he "lays no claims to the invention of a single new operation, nor has he produced a new or modified instrument, but has contented himself with applying to his surgical work what seemed best in the practice of the surgeons of the past and present."

The book simply reflects the methods of the author in his daily work, and no attempt is made to thoroughly cover any subject from a surgical point of view. Pathology is scarcely touched on, and much of the work consists in a detail of clinical cases and what was done for them. Some of the views held by the author will not be concurred in. For instance, there seems to be no good reason, when operating on a child for inguinal hernia, why the deeper layers should not be closed as well as when operating on an adult. His views in regard to the treatment of appendicitis have already been severely criticised by a number of surgeons.

The large plates are made a particular feature of the book. Some of them are very good, but Plates LVI and LVIII are libels on anatomy. The wide margin to the pages for marginal notes is of doubtful value, because one does not buy a book of this kind in which to write one's opinions, but to learn the opinions of the author.

The work must be looked on more as a detail of clinical cases than as a real contribution to surgery.



Dr. Gardner T. Swarts, Providence, R. I., Secretary of the Section on Hygiene and Sanitary Science.

Diseases of the Skin: Their Description, Pathology, Diagnosis and Treatment, with Special Reference to the Skin Eruptions of Children, and an Analysis of 15,000 Cases of Skin Disease. By H. Radcliffe-Crocker, M.D. (Lond.), F.R.C.P., Physician for Diseases of the Skin in University College Hospital. Third Edition, Revised and Enlarged. With Four Plates and 112 Illustrations. Cloth. Pp. 1466. Price, $5.00. Philadelphia: P. Blakiston's Son & Co. 1903.

Crocker's work on diseases of the skin has been a standard English treatise since the first edition appeared, and the appearance of a third edition is, therefore, only what might be expected. The present volume is greatly expanded and covers the subject much more thoroughly than the previous edition; in fact, it is one of the fullest treatises on skin disorders in our language. The illustrations, while not extensive, are useful. There are few, if any, skin diseases that are not described in this work. It seems to us, though, to be occasionally weak in regard to treatment and not entirely up to date. For example, it does not give the results of the latest experience with the *x*-ray management of certain skin diseases. The book will doubtless long hold its own among the many other excellent treatises on diseases of the skin.

Dr. John E. Weeks, New York, Chairman of the Section on Ophthalmology.

DISEASES OF THE STOMACH. A Text-Book for Practitioners and Students. By Max Einhorn, M.D., Professor in Clinical Medicine at the New York Post-Graduate Medical School and Hospital. Third Revised Edition. Cloth. Pp. 531. Price, $3.50 net. New York: Wm. Wood. & Co. 1903.

This is a fully revised edition of the author's former treatise with a number of additions, making it considerably different from the first edition, the second having been mainly a reprint of the first. Those who possess and depend on either of the former editions will find it necessary to obtain this one, the advances in this special department of medicine requiring considerable change to bring the work up to our present knowledge.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

To Remove Odors.

Dr. Cheves Bevill of Winfield, Ark., on reading the reference to the use of carbolic acid as a deodorant, on page 1020 of THE JOURNAL, April 11, suggests the use of spirits of turpentine either full strength or with equal parts of glycerin. He says that he has never found anything to be compared to it for this purpose. He reported its use in the "St. Louis Weekly Medical Review" in 1888. Turpentine may also be used on tampons or on absorbent gauze in cleansing wounds. Both the offensive odor and the tendency to hemorrhage will be lessened.

Hyperchlorhydria.

The following combinations have been used with success in the treatment of pyrosis:

℞. Bismuthi subcarb.	ʒiv	15
Tinct. hyoscyami	ʒiv	15
Aquæ camphoræ q. s. ad.	℥iii	90

M. Sig.: Shake and take one teaspoonful an hour before each meal; or:

℞. Argenti nitratis	gr. iv	25
Ext. hyoscyami		
Pulv. camphoræ, āā	gr. vi	35

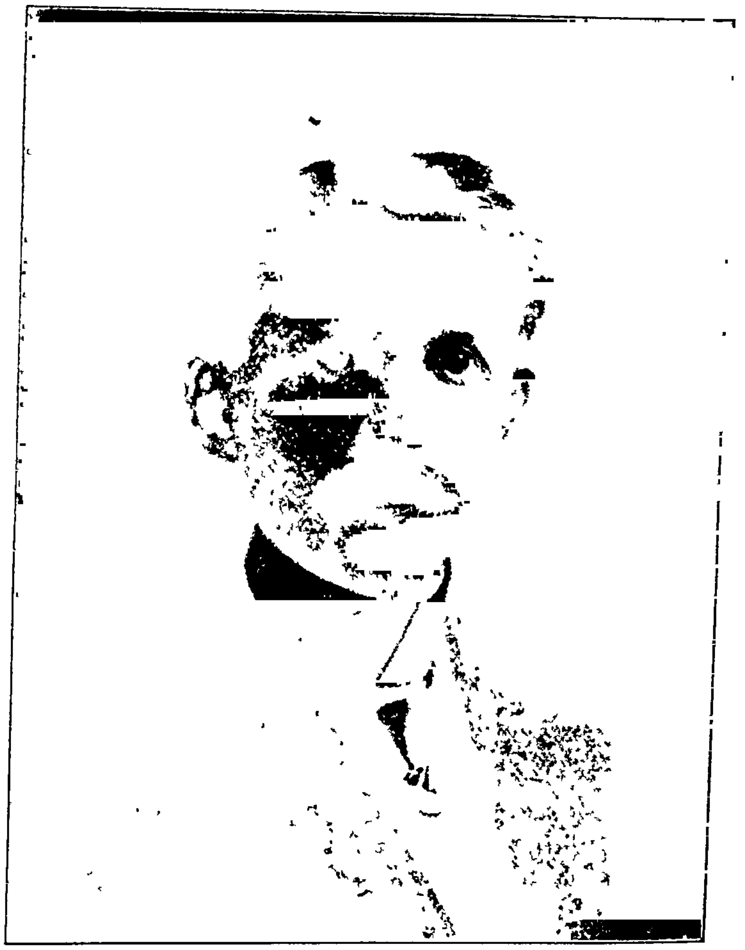
M. Ft. pilulæ No. xxiv. Sig: One pill to be taken one hour before each meal; or:

℞. Tinct. hyoscyami	ʒiv	15
Strontii bromidi	ʒiiss-v	10-20
Elix. simplicis q. s. ad	℥viii	240

M. Sig.: Two to four teaspoonfuls in a glass of water at meal time to relieve the distress.

Eczema.

The following combination is recommended by the "Indian Med. Gazette" in the treatment of eczema:



Dr. Frank C. Todd, Minneapolis, Secretary of the Section on Ophthalmology.

℞. Acidi borici	gr. xxx	2
Zinci oxidi		
Amyli tritici, āā	ʒvi	24
Liq. petrolati	℥xiii	52

M. Sig.: Apply twice daily with a glass rod Smear the salve thickly over the affected part and then cover it with a layer of cotton wool and apply a suitable bandage. The parts should be thoroughly cleansed every third or fourth day and a fresh application made. This may be repeated until all signs of inflammation have disappeared.

The following ointment is recommended by "Bul. Gen. de Ther." in the treatment of eczema:

℞. Naphthol camphoratæ	gr. viiss	50
Zinci oxidi	gr. lxxv	5
Liq. petrolati	ʒxii	48

M. Ft. unguentum. Sig.: Apply locally.

Sepsis Following Abortion.

Henry, in "Med. News," recommends the following outline of treatment of sepsis complicating abortion: Remove all debris from the uterus by means of the finger or sharp curette followed by flushing and thoroughly cleanse the raw surfaces, the cervix, vagina, and vulva. These raw surfaces should then be dried and a 95 per cent. solution of carbolic acid applied to them freely, washing away the surplus with sterile water. No tubes or packing should be left either in the uterus or vagina unless hemorrhage should require it.

Dr. John C. Cook, Chicago, Chairman of the Section on Diseases of Children.

According to the author a 2 per cent. carbolized vaginal douche should be used twice daily. The bowels should be kept free by the administration of one-half grain (.03) of calomel every hour for four hours, followed by the ordinary dose of salts.

Quinin should be given in three-grain doses (.20) every four hours, alternately with ferric chlorid given in fifteen minim doses (1.00) well diluted.

Nourishment consisting of milk, eggs and proper stimulants should be given every four hours.

Hemorrhoids.

According to an abstract in "N. Y. Med. Jour" hemorrhoids may be so treated medically as to cause no great discomfort, unless they become infected, if the rules of hygiene are properly observed. Sitz baths should be taken frequently. Moderate exercise only should be taken to diminish local congestion, over-indulgence in meat and spiced foods, while vegetables and fruits must be taken freely. The bowels must be regulated, a movement obtained, if possible, just before bedtime, as the hemorrhoids swell greatly after defecation and are reduced during the night. Instead of resorting to the use of drastic purgatives a teaspoonful of the following should be taken at bedtime:

℞. Calcined magnesiæ		
Potassii bitartratis		
Sacchari lactis, āā	℥ss	15

M. Sig.: One teaspoonful at bedtime.

Enemas are of value and may be taken cold. However, the author states that they are preferably taken hot when there is no pain, as the decongestive action of heat is more prolonged than that of cold. As an astringent, a teaspoonful of alum may be added to the enema.

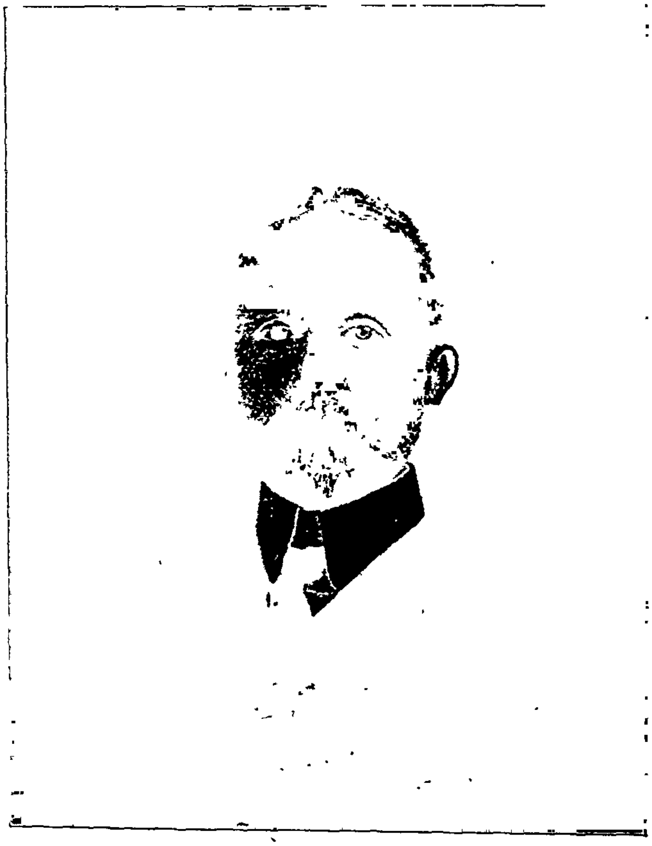
The following combination is sometimes recommended internally:

℞. Ext. hamamelidis	gr. 3/4	05
Ext. capsici aqueous	gr. iss	09

M. Ft. pil. No. i. Sig.: One such pill three or four times a day.

When the hemorrhoids protrude externally and are accompanied by pain, a pledget of cotton may be soaked in a 1 per cent. solution of cocain and applied locally; this will relieve the pain temporarily, but the inflammation must subside before permanent relief can be obtained. Applications of very hot or very cold water are recommended by the author or liquor plumbi subacetatis may be employed or spraying with hot boric acid solution. The anus must be kept clean and only absorbent cotton used in order to produce no irritation.

In cases of internal hemorrhoids coming down during defecation and returned with difficulty, the patient should be instructed to lie on his side with the lower thigh extended and the upper one flexed and with a compress soaked in water or olive oil they should be reduced with gentle taxis.



Dr. Thomas S Southworth, New York, Secretary of the Section on Diseases of Children.

The following combinations are recommended in the form of suppositories:

℞. Ext. krameriæ	gr. viiss	50
Cocainæ hydrochlor.	gr. 1/3	02
Ol. theobromæ	ʒi	4

M Ft. suppos. No. i. Sig.: One such to be used night and morning to relieve the pain.

Or the following, which is made up according to Unna's formula:

℞.	Chrysarobin	gr. v		30
	Iodoformi	gr. iss		09
	Ext. belladonnæ	gr. 3/4		05
	Olei theobromæ	ʒv	20	

M. Ft. suppos. No. v. Sig.: One to be inserted night and morning.

If hemorrhage should occur, cold applications may be applied or water containing 5 per cent of alum. Mathieu recommends a hot solution (118 F.) containing gr. 60 (4.00) of calcium chlorid tó the quart. If the foregoing proves unsuccessful the following suppository may be employed:

Dr. M. L. Rhein, New York, Chairman of the Section on Stomatology.

℞.	Antipyrini			
	Salol, āā	gr. iv		25
	Ext. belladonnæ	gr. 1/6		01
	Ol. theobromæ q. s.			

M. Ft. suppos. No. i. Sig.: To be inserted to check hemorrhage.

Internally the following is of service:

℞.	Calcii chloridi	gr. lx	4
	Syrupi simplicis	℥i	30
	Aquæ	℥iv	120

M. Sig.: One tablespoonful every hour.

Pertussis.

Fournier, in "Med. Bul.," recommends the following combination as an inhalation in the tréatment of whooping cough, which he states has been of great value to him in a recent epidemic:

℞.	Glycerini	ʒiiss	10
	Creosoti	m. lxxv	5
	Essentiæ terebinthinæ	ʒi	4
	Essentiæ eucalypti	m. xlv	3
	Essentiæ caryophylli	m. xv	1

M. Sig.: As an inhalation.

A mask similar to that employed in narcosis is used, and about ten drops of the mixture are poured on the center of the mask. Violent fits of coughing are noticed at first, when the mask should be removed until the child becomes accustomed to breathing the preparation.

Calomel in Children's Diseases.

The "Indian Med. Record," in commenting on the value of calomel in children's diseases, states that it may be given in three quarter grain doses (.05) for each year of age This dose may be given alone in the morning while fasting or mixed with equal quantity of scammony or jalap and may be administered in jam, honey, sweet mucilage, syrup or with sugar. It is slow in acting, requiring, perhaps, half a day. In the infective diseases of children the author recommends it in doses of grain 1/6 (.01) to grain 1/2 (.03) every two or three hours, according to age. In jaundice, congestion of the liver or cirrhosis it should be given in still smaller doses, gr. 1/6 (.01) to gr. 1/3 (.02) being given every morning for eight days. In the treatment of tapeworm it may be combined with the oil of male fern, and for ascarides it may be given in the following combination:

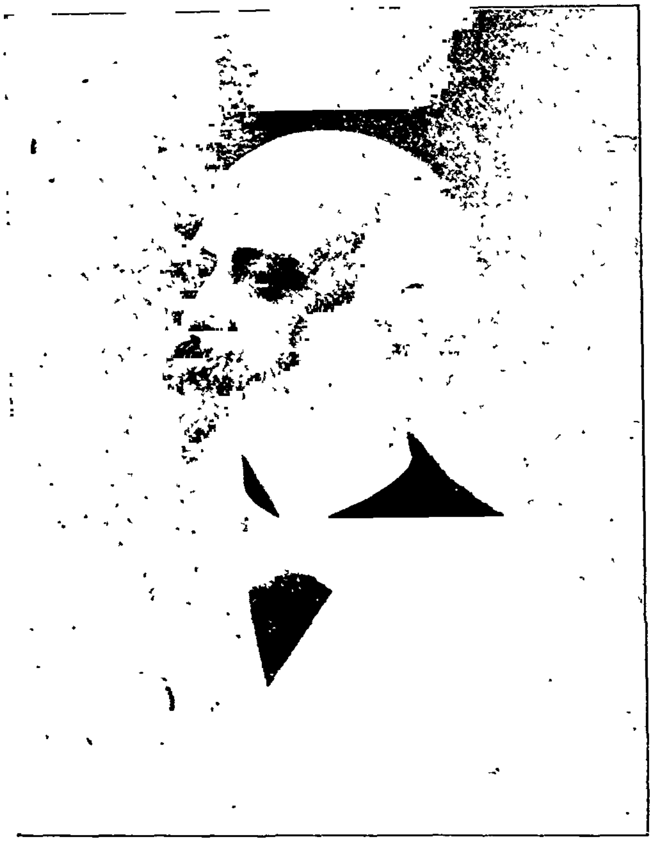
℞.	Santonin			
	Hydrarg. chloridi mitis, āā	gr. iii		20
	Sacchari	gr. lxx	4	65

M. Ft. chartulæ No ix. Sig.: Three to be given each morning, at intervals of one hour, for three days.

As a gastrointestinal disinfectant, in the treatment of flatulent colic of infants, it is recommended in still smaller doses ranging in size from grain 1/12 (.005) to gr. 1/3 (.02). It may be used in such doses as the foregoing in the treatment of vomiting, green stools and acute febrile gastritis or when the temperature rises in the course of subacute or chronic gastroenteritis, after the administration of which the temperature will usually drop. In the treatment of infantile cholera it is recommended that the stomach first be irrigated with warm water and as soon as the vomiting ceases the administration of calomel should be commenced, and continued every two hours

Dr. E. S. Talbot, Chicago, Secretary of the Section on Stomatology.

until ten or twelve powders have been taken, when it will usually show its good results. It is also recommended in the treatment of catarrhal jaundice of children. The following precautions are attached in the administration of calomel: When it is mixed with sugar it should be added at the time the powder is given to the infant; prolonged contact leads to some formation of corrosive sublimate. It should also be kept in the dark as exposure to sunlight decomposes it. Calomel is incompatible with chlorids, iodids and hydrocyanic acid; it should not, therefore, be given after a meal if salt has been used, nor with bitter almonds or cherry laurel water nor with the iodids.



Dr. F. W. Langdon, Cincinnati, Chairman of the Section on Nervous and Mental Diseases.

Medicolegal.

Taking Deposition of Busy Physician Not Authorized.—The Mississippi Code provides for the taking of depositions where on account of a witness being about to depart from the state, or because of his sickness, or other causes, he will likely be unable to attend trial But that one is a physician in large practice, "and that it is likely that the said witness will be unable to attend trial," etc., the Supreme Court of Mississippi holds, American Express Company vs. Bradford, does not bring the instance within the category meant by the words "or other causes" in the statute.

Physician May Write Prescription for Himself.—Article 405 of the Penal Code of Texas of 1901 provides, among other things, that if any physician shall give a prescription to be used in obtaining any intoxicating liquor in any county, justice precinct, city or town, in which the sale of intoxicating liquor has been prohibited under the laws of the state, to any one who is not actually sick, and without a personal examination of such person, he shall be punished, etc. The Court of Criminal Appeals of Texas holds, Hawk vs. State, that it was the intent of the legislature by this article to make it an offense to give a prescription to another party than the one writing the prescription, and that it is not unlawful for any one to write a prescription for himself.

By Whom Professional Attendance Must Be Proved.—In the case of Jennings vs. the Supreme Council of the Loyal Additional Benefit Association, brought to recover on a beneficiary certificate, the first appellate division of the Supreme Court of New York holds that the burden of showing that the testimony of a physician was privileged was on the party suing, who objected thereto. This was neither shown or attempted to be shown by the examination of the physician himself; and it did not appear from his examination, so far as the record disclosed, that he ever attended the insured professionally. And it will not do, the court thinks, to rule out the testimony of a physician on the ground that the evidence is privileged from the mere fact that some other witness has incidentally testified to professional treatment by the physician of the person concerning whose appearance or state of health the inquiry is made. Here, for aught that appeared, if the party suing had sought to show by the examination of the physician in question that his testimony was privileged, the physician might have denied that he ever treated the insured professionally. Furthermore, the court says, if it appeared that the physician had treated the insured professionally, the only privileged evidence would have been the information derived from such professional attendance. It was perfectly competent to show by him what he observed of the insured and knew of him on other occasions when not attending him professionally; for example, what he saw and learned of the insured's appearance and condition at times when he was attending other members of the family.

Dr. F. Savary Pearce, Philadelphia, Secretary of the Section on Nervous and Mental Diseases.

Mental Suffering as an Element of Damages.—The Supreme Court of Pennsylvania says, in Linn vs. Duquesne Borough, that mental suffering has not generally been recognized as an element of damages for which compensation can be allowed, unless it is directly connected with a physical injury, or is the direct and natural result of a wanton and intentional wrong. Where a claim is for mental suffering that grows out of, or is connected with, a physical injury, however slight, there is some basis for determining its genuineness, and the extent to which it affects the claimant. But as the basis of an independent action, mental suffering presents no features by which a court or jury can determine either its existence or its extent, and claims founded on it have generally been regarded as too uncertain and speculative for consideration. Excepting cases in some jurisdictions where recoveries have been had for the failure to deliver telegrams announcing illness or death, or other matters of personal concern, but not of pecuniary importance, the instances are very few in which an independent action has been sustained for mental suffering alone. The decided trend of decision both in this country and in England is against the maintenance of such an action, or the allowance for mental suffering as an element of damages when distinct from physical injury. The cases in which mental suffering has been considered as an element of damages are those in which the suffering was caused by the sense of peril at the time of the physical injury, or was incident to the physical pain, and formed a part of the actual injury. The objections to making mental suffering the sole ground of recovery apply with equal force to allowing it as an element of damages when it is not a part of the actual injury, but arises afterward from regret, disappointment, or anxiety. There are the same opportunities for establishing fanciful or fraudulent claims by testimony, which it is impossible to contradict or impeach, and the injustice of holding a party responsible for the unforeseen consequences of mere neglect is as great in one case as the other.

Dr. John A. Fordyce, New York, Chairman of the Section on Cutaneous Medicine and Surgery.

Sale of Practice with Agreement to Relinquish Office.—A physician sold a house and lots, his good will as a physician, and also agreed to relinquish to the purchaser his office for the practice of medicine and surgery. As the purchaser knew, he did not own the office in which he was situated, but, with another physician, as partners, had rented the office. The seller's partner expressed himself satisfied with the change, though subsequently proposed such terms for the use of the office, of which he had meanwhile obtained a lease, that the purchaser aforementioned declined to have more to do with the contract. Then the seller sued him for $500 damages for breach of contract, and recovered a judgment for $400. The Court of Appeals of Kentucky holds, Wallingford vs. Aitkins, that it could not, by any reasonable construction of the contract, be construed that the seller was to rent and pay the rent to the owner of the office for the purchaser. It also holds that when the purchaser announced by letter that he would not comply with his contract, this was a renunciation of the contract, and the seller then had the right to sue him for a breach of it. The jury were instructed that when the purchaser mailed to the seller the letter declaring that he declined to have anything more to do with the contract, the seller had nothing further to do in the premises; this was a renunciation of the contract on which the suit was founded; and the seller was entitled to such damages as the jury might believe from the evidence he had sustained by reason thereof, not exceeding the sum of $500, the amount claimed. The language of the contract that the seller agreed "to relinquish his office for the practice of medicine and surgery" to the purchaser, simply meant that he was to vacate the office and leave the same to the use of the purchaser, if he chose to occupy it, and if the jury believed from the evidence that the seller was able, ready and willing to so relinquish, then the law was for the seller, and the jury would so find. The measure of damages in this cause was the difference between the contract price of $3,500 to be paid the seller by the purchaser, under the contract, and the market value of the property at the time of the breach of the contract and when sold, not exceeding $500, the amount claimed. The court of appeals holds that these instructions were proper, and covered the law of the case.

1. **X-Rays in Pseudoleukemia.**—Senn reports two cases in which, in view of the hopeless condition, he suggested the use of the rays, in addition to giving arsenic and iron. The benefit was great, both patients now considering themselves in perfect health. He says in his remarks that there is no doubt that the constitutional disturbances which follow the prolonged use of the *x*-ray, and which set in simultaneously with the progressive diminution in the size of the glands, were due to toxemia caused by absorption of the degenerative products of pseudoleukemia. This was also undoubtedly the cause of the increased enlargement of the spleen, which was noted after the second series of applications in the second case. The constitutional disturbances were decided and annoying itching, burning, pigmentation, etc. He says the success attained in these two cases by the use of the *x*-ray leaves no doubt as to the curative effect of the rays in the treatment of pseudoleukemia.

2. **Rectal and Anal Disease.**—The forms of trouble which Gant would treat in the office or away from the hospital are external and internal hemorrhoids, in the latter of which he uses injections as well as the ligature, polypi in the rectum, anorectal abscess, fistula, fissure of the anus, ulcer, pruritus, constipation and fecal impaction. Cancer and stricture can hardly be operated on in the office excepting when in the lower rectum, but in most cases the local treatment and topical applications, etc., can do much toward improving the condition.

4. **The Diazo Reaction.**—The conclusions derived from investigations by this method in the laboratory of the New York Department of Health are given by Billings as follows:

1. The examination of the urine in cases of suspected typhoid fever is of value, provided that its limitations are recognized.
2. While not so absolutely pathognomonic of typhoid fever, yet the diazo reaction is even more constantly present in that disease than the Widal reaction. So that its absence at a period when it should be present, if the case is one of typhoid fever, is of considerable value in making a negative diagnosis.
3. In a majority of instances the diazo reaction is present in the urine at least forty-eight hours earlier than the Widal reaction in the blood.
4. It disappears much earlier than the Widal reaction, however, and negative results obtained later than the second week are of little or no value.
5. "Doubtful reactions" have slight significance.

5. **Typhoid Fever Complications.**—The complications of typhoid discussed here by Erdmann are liver abscess, perforation of the gall bladder, cholecystitis and intestinal perforation. The operative treatment of each is discussed. For liver abscess, opening, either by rib excision or otherwise, is advised with subsequent drainage. He does not believe in delaying pus evacuations at the expense of the patient's vitality. In cases of perforation of the gall bladder there is only one treatment, he says, cholecystectomy, though the condition of the patient must weigh with us somewhat in the consideration, and cholecystotomy must be done in certain cases. Repair by suture is unwarranted. Operative interference in cholecystitis depends largely on the symptoms presenting. If marked rigidity of the upper rectus segment continues for thirty-six to forty-eight hours without any diminution, and septic conditions are indicated by the temperature and pulse, or rupture of the

Dr. J. F. Barnhill, Indianapolis, Secretary of the Section on Laryngology and Otology.

bladder threatens, then cholecystotomy should be performed if the patient's condition is bad or cholangitis is present; otherwise cholecystectomy. In all cases the abdomen may be closed without drainage unless we leave the cystic duct open for drainage of the hepatic fluid. The statistics of the operation for intestinal perforation are noted and the principal question seems to be whether we should wait six to twelve hours for subsidence of shock. He is inclined to answer this in the negative from his study of the statistics. The suture to be employed is either the Lembert or the circular purse-string when inversion is possible. The question of drainage can be settled only by experience. He believes that with a fairly clean toilet, no drainage should be used.

Dr. S. Solis Cohen, Philadelphia, Chairman of the Section on Materia Medica, Pharmacy and Therapeutics.

6. Vital Processes.—Clements' article is an argument in favor of the vitalistic point of view in physiology.

April 18.

8 *A Report of Final Results in Two Cases of Polyarthritis in Children of the Type First Described by Still, together with Remarks on Rheumatoid Arthritis. Royal Whitman.

9 *"Eye-strain" in Youth and Its Modern Treatment. Ambrose L. Ranney.

10 Tuberculous (Basilar) Cerebrospinal Meningitis and Delusional Insanity Complicating Pulmonary and Laryngeal Tuberculosis. Henry Levien.

11 *Resection of Intestine, with Report of Three Interesting Cases. A. E. Isaacs.

8. Polyarthritis of the Still Type in Children.—The two cases reported by Whitman are, as he says, undoubtedly samples of the disease described by Still in 1897, consisting in general chronic progressive enlargement of the joints, with general enlargement of the glands and spleen. The cases are elaborately reported, with illustrations and radiograph. One of them recovered, which is apparently decidedly different from the usual course of the disease. Recovery in this case was apparently completed by an attack of acute disease, scarlatina, after which the patient regained his former health. The author remarks in regard to the nature of rheumatoid arthritis, and seems to doubt the infectious nature of the disorder as well as other theories that have been advanced.

9. Eye-Strain in Youth.—Ranney discusses this disorder and insists on its importance. His conclusions are:

1. Eye strain can not be recognized too early in youth.

2. Its scientific investigation by modern methods and its radical correction may favorably modify both physical and mental development.

3. The neglect of an existing eye-strain may in time allow it to exhaust the reserve nerve capital of the sufferer and produce untold ills both of body and mind.

4. No child should ever be allowed to begin education until it is known that its eyes are properly fitted for the work.

5. Legislative enactment should, and surely will in time, compel an eye examination of every child before it enters the public schools.

6. Teachers should also be instructed in the rudimentary steps of vision testing.

7. Tests for mal-adjustment of eye-muscles should be made on every child as thoroughly and intelligently as tests for errors of refraction are made prior to its education.

8. A knowledge of the possible effects of eye-strain on mental and physical development can not be too widely disseminated among parents and teachers.

9. The direct causal relationship between "eye-strain" and nervous diseases is too well established to-day to require further proof, or even to justify further discussion.

10. The modern methods of testing for anomalies of adjustment of eye-muscles are the only ones that can furnish us with scientific and accurate information.

The time has happily passed when any oculist can instruct a patient to simply follow with the eyes some object held before the eyes, and then on that test alone give a final decision as to whether mal-adjustment of the eye muscles exists or does not exist.

11. The cure of disease to day is intelligently based on the search *for its cause* rather than on an indiscriminate use of drugs; and the prevention of diseases is rapidly becoming more important to the medical mind, and also to the laity, than its cure.

Dr. C. S. N. Hallberg, Chicago, Secretary of the Section on Materia Medica, Pharmacy and Therapeutics.

12. The detection of "eye strain" in youth is an important step in preventive medicine, and the arrest of a nervous leak may save many a child from a permanent break-down when an adult.

13. The study of facial expression and head posture is destined to become an important aid in diagnosis.

14. The governing boards of institutions for the feeble-minded, the epileptic, and the insane will sooner or later be compelled to investigate more carefully and earnestly than in the past the eye conditions of their inmates.

11. Intestinal Resection.—Three cases of interest are reported by Isaacs. The first two show how uncertain the diagnosis of acute appendicitis may be, even if the symptoms are apparently clear. The first case is also of interest on account of the length of the gangrenous gut, twenty-three inches, included in the intestinal strangulation. The operation with the Murphy button was successful, the button passing the ninth day after operation, and the patient was discharged cured in four weeks. In the second case the symptoms were those of an acute attack of appendicitis with local suppuration, but examination disclosed the appendix perfectly normal, though just above it was a tumor consisting of inflamed omental and cecum adhesions matted together with the parietal peritoneum, and a large abscess was found posterior to the cecum and the ascending colon. This arose from the lumbar spine, and instead of working its way down the psoas muscle took the unusual course of working forward through the abdominal cavity, and pointing toward the site of the usual appendiceal abscess. The appendix was ligated and removed, but, as it turned out, this was ineffectual in closing the appendicular orifice, resulting in fecal fistula. The patient was a boy only eight years old, and he successfully withstood five severe laparotomies within five months, coming out none the worse excepting for the presence of scars and a possible future hernia. The third case was a strangulated femoral hernia so far advanced that strangulation of the constricted end and suppuration of the sac had already taken place The operation was performed with the Murphy button as in the other cases, and with good results notwithstanding the desperate condition of the patient, a widow 56 years of age.

12 *The Syphilitic Nature of Tabes and General Paralysis. Dr. Leredde.
13 Pulmonary Abscess Producing Dextrocardia: A Case Report. Thomas L. Coley.
14 Methods of Roentgen-Ray Treatment of Malignant Diseases of The Uterus, Rectum and Bladder, with Descriptions of Tubes. Margaret A. Cleaves.
15 *The Surgical Treatment of Tubercular Peritonitis. D. S. Fairchild.
16 *The Operative Treatment of Laryngeal Tuberculosis. Lorenzo B. Lockard.
17 Pernicious Anemia following Thyroid Enlargement. V. S. Merritt.

12. **Tabes and Paresis.**—Leredde holds to the syphilitic nature of these disorders and their curability under specific treatment. He does not believe in pseudo-general paralysis of syphilitic origin definitely distinct from the true disease, but there is a certain clinical type of cerebral syphilis identical with and impossible to differentiate from true general paralysis. This is singularly frequent. He believes that general paralysis in a syphilitic patient is always syphilitic in nature and may be cured if treated correctly before degeneration occurs. He gives details as to treatment, insisting on the importance of a gradual increase of the mercurial dose to avoid any sudden action of the drug.

15.—See abstract in THE JOURNAL of January 17, p. 189.

16. **Laryngeal Tuberculosis.**—Lockard believes in the surgical treatment of these cases; however, carefully selecting them for operation. For the results to be good, the lesions must be localized and accessible, the pulmonary process incipient or quiescent, and there should be general good health without hyperpyrexia, cardiac weakness and involvement of other organs, and a favorable moral and mental temperament. Lastly, and of great importance, a local, not constitutional susceptibility to cocain. The various operations, curetting, use of the knife, scissors, etc., are mentioned. He would also operate to alleviate or render stationary, disease in cases of gradually increasing stenosis, severe laryngeal tuberculosis with slight pulmonary involvement, and when new infiltrations and ulcerations occur after treatment or when local treatment can not be given on account of lack of skill or too widespread involvement, but the inefficiency of all other methods should first be demonstrated. He thinks, in any case, we may anticipate some lessening of pain, increased facility in eating and some subsidence of swelling and inflammation. When the pulmonary condition is not in itself fatal, we may also anticipate some resolution in the diseased tissues, a favorable influence on the lungs, a considerable prolongation of life and, rarely, a cure. He thinks that the treatment of a tubercular larynx should usually be the same

Dr. Joseph McFarland, Philadelphia, Secretary of the Section on Pathology and Physiology.

as a case of tuberculosis of other parts, that is, complete removal of diseased tissue at the earliest moment provided a conscientious trial of the more conservative methods has first been made.

22 Angioneurotic Purpura. Raymond Wallace.
23 *Limitations of the Dimethylamidoazobenzol Test for Free HCl in the Stomach Contents. Wilbur F. Skillman.
24 *Infection as a Factor in Tuberculosis. Woods Hutchinson.

18. **Malignant Disease of the Testicle.**—Cumston and Rolfe plead for a more thorough operation in these cases, performing not merely a castration, but dissecting out the lymph glands in the groin. The article is illustrated.

19. **Scarlatina.**—Eighteen cases of scarlatina have been studied by Weaver to ascertain the bacteria of the skin in this disease. He finds that the bacteria obtained from the cultures of the skin, epidermic scales, and the surface of the tonsil in case of scarlatina are the same as those found in the same localities during health, no one of these is constantly present except the streptococcus in the throat. On account of the numerous cocci growing in such cultures it is impossible to identify them except by complete study. If made by inexperienced persons or those who do not fully appreciate the importance of avoiding the tongue, the cultures are especially apt to contain large diplococci or sarcinæ. The streptococcus is present in the tonsil of scarlatinal patients in enormous numbers in almost every instance.

20. **Insomnia.**—The causes and treatment of insomnia are discussed at length by Richardson, who reviews the effects of various hypnotics and practically condemns them all as being toxic and producing sleep by intoxication. The methods which he would consider better are sleeping in a well-oxygenated room, keeping the bed warm, reduction of mental activity for some hours before going to bed, and the evening meal at least four hours before retiring; the use of the bath immediately before retiring and sometimes the addition of a nitroglycerin or erythrol tetranitrate tablet after the patient has gone to bed. Small doses of digitalis in neurasthenic cases will sometimes be efficient in producing sleep. In acute mania with low mean and maximum blood pressure, heart stimulants are indicated, but in chronic mania, with high mean and maximum pressure, these are useless and opiates are especially contraindicated. There are cases where hypnotics are absolutely necessary, but he thinks it is better to produce the conditions necessary to natural sleep than to give a poison which produces unconsciousness and not sleep, and which must be detrimental to the patient.

21. **Variola.**—Chance has studied the ocular complications of variola in an analysis of over two thousand cases at the Municipal Hospital at Philadelphia. He finds ocular affections common, occurring sometimes in the acute stages and again not until convalescence, or they may be seen for the first time as sequelæ. The skin of the lids is commonly a site of the pustulous eruption and the eye may not be opened for several days. In such cases severe conjunctivitis is present and often leads to corneal ulceration and abscesses may occur on the lids later The lachrymal passages may become inflamed and destroyed. Inflammation of the conjunctiva itself is usual, but shortly passes away. The intensity is related directly to that of pustular eruption in general. The cornea does not seem to be subject to the specific lesion of variola, though ulceration does occur independently of the general process as a consequence of conjunctival disease. Inflammation may be only a slight superficial haze or may involve the entire membrane. In severe cases rapid destruction of the cornea may take place as early as the eighth day. Sometimes both the eyes are affected. Two cases of parenchymatous keratitis were observed. Old vaccination, though not effective against the smallpox seemed to relieve the corneal complications to a considerable extent. The uveal tract seemed less likely to be affected than the cornea. Iritis was observed in a few cases. In no case was there circumscribed choroidal inflammation or posterior polar cataract. Chance can report no case of glaucoma, retinitis or neuro-retinitis, though other observers have reported such. While kidney disease was common it did not progress far enough to result in any case of albuminuric retinitis. He has not found any cases of hemorrhage into the retinal sheet or optic nerve reported as actually observed.

23. **Dimethylamidoazobenzol Test.**—Skillman finds certain limitations of this test for free HCl in the stomach, which he summarizes as follows:

1. If the test for lactic acid is positive, Gunzburg's or Boas' reagents, or some other method, should be used to determine whether our dimethyl reaction is due to lactic acid or to free HCl.
2. If the stomach is normal both as to size and position and the peristaltic function is unimpaired, then dimethyl will give fairly accurate results.
3. If the size and position of the stomach are not normal (gastrectasis or gastroptosis), or if the peristaltic function is delayed, then Gunzburg's or Boas' tests should be first performed to test positively whether free HCl is causing reaction, or whether it is caused by organic acids, before proceeding to titration with dimethyl.

24. **Tuberculosis.**—Hutchinson gives an interesting résumé of the present conditions of the question of bovine and human tuberculosis, disagreeing with Koch as to the harmlessness of bovine tuberculosis to man, though he admits his general statement as to the transmission of human tuberculosis to cattle. As regards actual infection from individuals, he finds little to support the extreme opinions which have gained ground. The general balance of evidence in regard to the rôle of infection in tuberculosis seems to him to point to the view that while the introduction of infectious material is necessary, the most potent factors in determining the questions of the development of the disease are those of the soil, viz., resisting power, and environment. He believes there is considerable in the *habitus phthisicalis*, that is, special conformation and physiognomy of those most subject to phthisis, and gives special importance to a high chest index, namely, the relation between the anteroposterior and the transverse diameters of the chest. This is high in consumptives, that is, the phthisical patient has a more round than flat chest. It is a persistence of the fetal condition. He believes in guarding against infection by every possible means; meat and milk inspection, tuberculin tests, destruction of sputum, notification of cases, prevention of expectoration in public, but twice as important, in his opinion, are well-aired rooms, good food, short hours of indoor work and an open-air life.

Boston Medical and Surgical Journal.

April 16.

25 *A Case of Interscapulo-Thoracic Amputaton for Sarcoma of the Brachial Plexus. F. B. Lund.
26 *The Diagnosis of Gonorrheal Urethritis. Alfred H. Gould.
27 *Cream for the Home Modification of Milk. Charles W. Townsend.
28 *Variation in the Composition of Human Milk. Philip P. Sharples and Eugene A. Darling.
29 *Trikresol in Para-urethral Abscess. M. L. Heidingsfeld.

25. **Interscapulo-Thoracic Amputation for Sarcoma.**—The case reported by Lund was a patient 40 years of age, of good muscular development, operated on for sarcoma of the brachial plexus following injury. Rupture of the axillary vein had occurred in attempted removal, and it was relieved by suture and subsequent interscapulo-thoracic amputation was performed with good results, and no recurrence after three months. The points of special interest are the close relations in time between the development of the tumor and the injury of the arm. The early paralysis of the median nerve, while the other nerves were not affected except by pressure, pointed to the origin of the tumor in this nerve. Lund summarizes the indications for this operation: 1. In the majority of cases of malignant disease of the humerus, and especially any that involve the tissues about the shoulder joint. 2. In malignant disease in the axilla involving the axillary vein, which can not be ligated without sacrificing the arm 3. In extensive injuries, where the scapula has been partially or completely torn away, or the skin over the deltoid has been destroyed, so that it is not available for the covering of an ordinary shoulder-

joint amputation. Points in the technic are noted, the importance of ligating the artery before the vein, and of cocainization of the trunks of the brachial plexus before division, which seems to have no effect on the pulse.

26. **Gonorrheal Urethritis.**—Gould insists on the importance of culture tests as well as microscopic tests to positively establish the identity of the disease. He advises the following general routine method: 1. Cleansing the meatus with water and passing the urine into a sterile test tube. This is centrifugalized in two sterile centrifugal tubes, and the overlying fluid poured off. The sediment is used for cultures. If a few gonococci are found in the first tube, the second tube is treated in the same manner. The Gram stain should always be used. In making culture media he found hydrocele fluid most practicable.

27. **Cream for the Home Modification of Milk.**—The conclusions of Townsend's article are given in the following:

1. Centrifugal cream is probably less desirable for infant feeding than gravity cream. As obtained from dealers it is often far from accurate in percentage.
2. Siphonage for obtaining gravity cream is an accurate method, but one requiring considerable skill to perform accurately and safely.
3. Dipping off the top milk is an accurate and safe method if reasonable care is used.
4. The method for obtaining gravity cream by pouring off the top is very accurate and extremely simple. There is no instrument to be bought and kept clean. By this method it is possible to obtain cream of any desired percentage up to 26 per cent.
5. To ensure perfect accuracy, frequent examinations with the Babcock machine are required; but for practical purposes this is not necessary, provided the mixed milk from a well-regulated dairy is obtained.

28. **Human Milk.**—Sharples and Darling have systematically analyzed samples of human milk collected under uniform conditions. The details of their methods are given. They find that the average composition of human milk as shown by 117 analyses is:

Fat	2.91	Ash	0.13
Sugar	7.01	Total solids	11.39
Proteids	1.34	Solids not fat	8.48

Very wide variations from the average occur in some individuals at different times and marked variations in the average composition from different individuals The average composition of human milk does not vary markedly at different periods of lactation, but during the first lactation it is weaker in fat and proteids and stronger in sugar than in subsequent lactations. These differences may or may not be due to age.

29. **Para-Urethral Abscess.**—Heidingsfeld gives his experience with four cases of para-urethral abscess following gonorrheal infection and treated by injections of trikresol. In all four it effected a complete cure in from seven to fourteen days, and materially shortened an exceedingly obstinate and distressing gonorrhea. He speaks rather strongly in regard to the utility of this preparation in such cases, and thinks it warranted in every accessible case until its efficacy, unfailing or otherwise, is fully established.

35 The Roentgen Ray: Its Mechanics, Physics, Physiology and Pathology. Eden V. Delphey.
36 The Congenital Criminal. Robert T. Irvine.

30. **Intestinal Indigestion.**—The different forms of intestinal indigestion are noted by Hemmeter, who commences with a discussion as to the gastric function, showing the importance of psychic incitation to gastric secretion. It is important first of all, in order to have a normal intestinal digestion to see that the mouth and stomach are in good order. He points out the differences between the jejunal and the catarrhal types of the stools; the former is very rich in bile pigments, with slight fecal odor and generally of an acid reaction, bearing evidence of simply being hurried through the intestine, while the catarrhal shows the presence of epithelium and round cells from the mucous membranes which are absent in the jejunum stools, and it is dependent on general enteritis. The dystrypsia due to carbohydrate fermentation which gives rise to jejunal diarrhea is important because it may entail an ultimate enteritis in either adult or infant. It is not an easy matter to decide between a normal and abnormal, quantitative or qualitative, presence of starch in the feces, but if they give a marked primary fermentation according to Adolf Schmidt's test, he excludes starch from the diet. Normally, Lugol's solution should show no blue color in the stools. An abundance of undigested muscle fibers after a weighed test diet is always significant of abnormal intestinal digestion, and if the nuclei in the muscle fibers are very evident it signifies abnormality of the pancreatic secretion. The presence of connective tissue is another significant point indicating gastric indigestion. According to Hemmeter's experience it is impossible to succeed with a radical enforcing of strict diet of any kind, but he advises a "bland diet"; foods that pass the intestinal canal undigested should be avoided. He makes it a rule to prohibit alcohol, tea, coffee and tobacco, but with great exhaustion he allows small quantities of alcohol under the strictest control. The diet can not be regulated until a dietetic experiment is made. The same holds true as regards constipation. We must ascertain whether this is due to atony or spasm. The majority of these patients require exercise after meals; a few may require rest. Great care must be exercised as regards the last meal of the day; a heavy supper will often produce a restless night. Hypnotics should be avoided for insomnia, and any neurasthenia properly combated. He has been able to get along without intestinal antiseptics, and has seen bad results from irritating drugs of this kind. Creosote, even in small doses, generally deranges the stomach. He gives a number of formulas for special symptoms.

31. **The Etiologic Factors of Intestinal Dyspepsia.**—The first of the exciting causes noted by Smith is the pathologic and anatomic alteration of the intestinal walls, nerves, lymphatics and blood vessels. 2. The absence or deficiency of the intestinal digestive secretions, especially of bile and pancreatic juice. 3. Intestinal indigestion due to qualitative or quantitative irregularities of diet. 4. Intestinal dyspepsia due to abnormal bacterial activity. 5. That due to abnormal gastric chemistry. 6. That of nervous origin—neurasthenia intestinalis. 7. Intestinal dyspepsia caused by abnormal substances, or irritation, reaching the intestines from the blood, as in uremia, severe malaria, septicemia, croupous pneumonia, erysipelas, cholera, etc. 8. Intestinal dyspepsia due to the activity of the intestinal parasites (exclusive of bacteria). 9. That due to hyperperistalsis or excessive motility of the bowel, motor, sensory, secretory neuroses, etc. All these are discussed in detail.

32. **Tetanus.**—Three cases are reported by Luckett, two recovering under intraspinal injections of tetanus antitoxin with withdrawal of a certain amount of cerebrospinal fluid. No attempt was made to maintain an equilibrium between the amount of spinal fluid withdrawn and the amount of serum injected, the former ranging from 100 to 140 drops and the latter usually 8 to 12 c.c. of antitoxin. He holds that this fact indicates that the shock or collapse following spinal subarachnoid injection of cocain is not due to any upsetting of equilibrium of pressure, but is due solely to the physiologic action of the cocain. In case of a tetanus infected wound he is not by any means positive that the anatomical seat of the wound does not play an important rôle in the production of the constitutional symptoms of tetanus; if near a large nerve it will be more likely to be followed by constitutional effects. While recognizing the absurdity of trying to draw conclusions from two cases, in the two patients who recovered the reaction after each injection was so prompt and the improvement so positive that he believes spinal subarachnoid injection of tetanus antitoxin, preceded by the withdrawal of the active, concentrated, highly toxic spinal fluid, supplemented by forced nutrition and proper care of wound, is a very promising method of treatment, offering more hope than any other in this dreaded disease.

33. **Staphylococcus Infection.**—Libman has examined 23 cases of osteomyelitis in septic conditions and found in all of them the *Staphylococcus aureus* in the blood during life. In 330 other blood cultures he has never seen a single colony of *Staphylococcus aureus.* Five of these 23 cases recovered. It does not necessarily follow that the greater the number of bacteria in the blood, the less the chance of recovery. The number of bacteria depends in some cases at least on the time when the examination is made, as the great tendency is for the body to rid itself of bacteria.

34. **Itching.**—Bronson reviews the causes of the symptom of itching and its treatment. Scratching is the natural remedy for itching, but may do more harm than good, but the principle of transference or substitution of sensation, used in scratching, is also applied in other remedies. One of the most valuable of them is menthol, which is not an anesthetic, but relieves itching as it relieves pain, by substitution for this sensation, the disturbance of temperature sense. A 2 to 4 per cent. alcoholic solution is most effective. Other remedies act as cutaneous anesthetics, as hot water, camphor, etc., and of the local anesthetics, carbolic acid is the most valuable and has the most lasting effect. To obtain its best effect it should be used strong. Its corrosive action on the skin is its chief objection. It is well to bear in mind the possibility of carbolic poisoning, though if ordinary caution is observed there is not much danger. The danger of injury to the skin from the caustic action is a more imminent one. We can use subsequent applications of alcohol if necessary. Generally he has found a drying oil, linseed more particularly, the best corrigent. The following is the prescription which he recommends:

℞. Liquor potassi	ʒi	4	
Acid carbolici	ʒii	8	
Olei lini q. s. ad	℥i	30	
Olei verbenæ	m. ii		12

M.

There is not much to be said for internal remedies, but where an urticarial element is prominent, there would seem to be an indication for motor depression to overcome the spastic contractions of the skin muscles. Atropin and pilocarpin are sometimes prescribed, but he does not strongly recommend them. In toxic urticaria there is an indication for antiseptic remedies and with the form due to errors of diet or dependent on idiosyncrasy of the individual, a brisk emetic or later a saline purge may be effective. In senile pruritus he speaks particularly of general stimulation of the skin by elimination, faradization, etc., with internally cannabis indica and strychnia. For pruritus hyemalis it is important that digestion and general nutrition should be kept up and alcoholics avoided. Bath pruritus is more difficult to control, and some times the addition of salt to the water makes it less irritating. For pruritus of the anus or genitals the cause should be searched out, all possible sources of reflex irritation looked for as well as any general condition like lithemia, neurasthenia, or diabetes. Among the local remedies he mentions lotions of aluminum acetate, Lassar paste, without salicylic acid, or with 2 or 3 per cent. carbolic acid. Orthoform may do well if inflammation exists and until it is allayed. Cocain is sometimes useful, but not good for prolonged use. The sovereign remedy for pruritus vulvi or ani is carbolic acid. A single application of the prescription above given is sometimes efficient for the whole night, but it should not, however, be applied too lavishly or too often; more than one or two applications in twenty-four hours would be likely to do injury. Hot water is often useful. Other remedies are also mentioned.

April 11.

41 *Fistula of the Cornea. James M. Ball.

41. **Fistula of the Cornea.**—This condition, which is rare in occurrence, is treated by Ball as follows:

> The keratome is to be introduced into the anterior chamber as in the first step in the operation for iridectomy. The tip of the instrument is to pass beyond the fistulous area, and the instrument is then to be held *in situ* while a cautery is used to destroy the epithelial lining, the tag of iris-tissue which is often present in the fistula, and the bulging bleb of Descemet's membrane. The keratome is to be withdrawn carefully to avoid injury to the lens. Atropin and a compress bandage are to be used in the after-treatment. During the operation the lids should be separated by a speculum and the eyeball should be fixed with forceps. It is necessary that the forceps should be placed several mm. behind the point at which the keratome is to be introduced. If the forceps be placed on the globe at a point opposite the place at which the keratome is to be passed, the globe may be subjected to sufficient pressure to cause a rupture of the weakened area. The operation must be postponed until such time as the anterior chamber shall have reformed.

42 Plague in the Orient. William J. Calvert.
43 *Pemphigus Vegetans. L. P. Hamburger and Maurice Rubel.
44 *The Taste Fibers and Their Independence of the N. Trigeminus. Harvey Cushing.
45 On the Use of Clay Modeling in the Study of Osteology. Robert O. Moody.
46 The Treatment of Aural Exostoses. H. O. Reik.

43. **Pemphigus Vegetans.**—Hamburger and Rubel report a case with details, autopsy findings and bacteriologic examination. The condition is a fatal one and was best relieved by continuous immersion under water. Cultures revealed the presence in the mouth of small bacteria in almost pure culture, allied apparently to the pseudo-diphtheria bacillus. After the death of the patient, the *Micrococcus lanceolatus* was isolated from the lungs, and a pseudo-diphtheria bacillus from the blood. Blebs showed the staphylococcus. The article is elaborately illustrated.

44. **The Taste Fibers.**—Cushing has analyzed the literature and a number of cases of his own observation to determine whether the taste fibers reach the tongue through the trigeminus or not. Judging from the uniform results of observation, he says it may be said in conclusion:

> 1. That the perception of taste is unaffected on the posterior portion of the tongue and never permanently or completely lost on its anterior two-thirds after removal of the Gasserian ganglion. 2. That a temporary abolition or lessening of the acuity of taste may be found to exist over the anterior and anesthetic portion of the tongue for some days after the operation. 3. That this temporary loss of function may possibly be occasioned by some interference with chorda transmission brought about by a mechanical or toxic disturbance due to degeneration of the N. lingualis. 4. That a lesion of the trigeminal nerve may be associated with disturbance of taste over the chorda territory without the necessary inference that the nerve is a path for gustatory impulses. 5. That the N. trigeminus in all probability does not convey taste fibers to the brain either from the anterior or posterior portion of the tongue.

58 *Hepatic Duct Stones. Raymond C. Turck.
59 *Primary Carcinoma of the Vermiform Appendix, with a Report of Three Cases. Arthur W. Elting.
60 *The Surgical Treatment of Anuria. Arthur D. Bevan.
61 *Results of Decapsulation of the Kidney. Harold A. Johnson.

51. **Splenopexy.**—Hall reports a case successfully operated n. The conditions were good for splenectomy, but noticing hat there was a peculiar structure of the spleen which favored ts attachment, the notch being specially situated so as to nake sure of an anchorage, he adopted the plan of splenopexy vith good results. Of course, this would not be advisable in every instance.

52. **Urethroplasty.**—Berg describes the various methods of performing urethroplasty and reports two cases showing the usefulness of Guyon's operation—that is insertion of a catheter and allowing regeneration over it between the two divided ends—which he holds is the most universally applicable method, though not so ideal as the union of the two ends.

53. **Marjolin's Ulcer.**—Two cases of this condition are reported by DaCosta, who discusses the origin of the cancer from chronic ulcer. He does not adopt the parasitic view, though certain things seem to favor it, such as metastases, etc. He cautions in regard to diagnosis, especially in cases where there has been a pre-existing induration, and the possibility of a syphilitic condition is mentioned. When a positive diagnosis is made of cancer of this sort on the extremities, the only course is amputation well above and removal of the anatomically related glands. The *x*-ray may be tried before amputation if the glands are not obviously enlarged.

55.—This article appeared in THE JOURNAL, Jan. 24, p. 246.

56. **Primary Tuberculosis of the Breast.**—Schley reports a case of this condition and discusses its pathology. The condition is evidently not a common one. It may be mistaken for simple cyst, fibro-adenoma, carcinoma, sarcoma, gumma and actinomycosis. It may also be necessary to distinguish the process from chronic interstitial mastitis. The treatment consists in removal.

57. **Intestinal Injury from Contusions.**—Several cases of this condition are reported by Le Conte and the symptoms and diagnosis analyzed. He thinks that a moderately sure diagnosis of injury must be made before operation is undertaken or we will frequently find no internal trauma, and that the teachings of modern writers who urge operation in all cases presenting pain, rigidity or local tenderness are too radical. The presence of shock is not sufficient for diagnosis. We must wait for reaction. No one symptom is pathognomonic, but the most reliable ones are gradually increasing rigidity and facial expression. Next he would place deep and perhaps radiating abdominal pain, respiration which becomes more and more thoracic, vomiting after shock has ceased, distension, increasing pulse-rate, and secondary fall in temperature. The order of these symptoms is unimportant. Any individual who has received an abdominal contusion sufficiently severe to call for service needs the most constant and careful watching for grave symptoms. We should not wait for them to become so pronounced that a positive diagnosis is assured, but there is a safest position midway between operation on every case and waiting for assured diagnosis.

58. **Hepatic Duct Stones.**—Turck emphasizes the importance of a thorough search for calculi in the hepatic duct and their removal if existing. He thinks it is safer to assume that stones may be formed in the bile ducts independently of gall-bladder influences, and unless the case is undoubtedly uncomplicated, or one with a few or a single large stone in the ducts, with no sign of cholangitis and with the bile clear, simple gall-bladder drainage, removal of the mucous membrane and cholecystectomy may all prove insufficient and drainage of the hepatic duct by tube through a direct incision or common duct opening should be instituted.

59. **Primary Carcinoma of the Vermiform Appendix.**—From a careful study of the subject including examination of three cases, Elting draws the following conclusions:

> 1. Primary carcinoma of the appendix is not of such rare occurrence as has been hitherto supposed. 2. Every appendix removed at operation or autopsy, if it presents any evidence whatever of disease, should be examined most carefully, and sections should be made from several portions of the organ for microscopical study. 3. The relationship of primary carcinoma of the appendix to chronic appendicitis, especially of the obliterative type, seems to be fairly definitely established. 4. Primary carcinoma of the appendix shows a tendency to develop at a comparatively early period of life. 5. Primary carcinoma of the appendix does not show a marked tendency either to extension or to metastasis. 6. The symptoms of primary carcinoma of the appendix are usually the symptoms of appendicitis of the chronic type. 7. The diagnosis of primary carcinoma of the appendix is in the great majority of cases impossible. 8. The treatment of the condition should always be operative.

60. **Anuria.**—Bevan reports a case and discusses the conditions which may be due to obstruction, traumatic or otherwise, from acute nephritis, from tuberculosis from degenerative conditions, from certain poisons, from a peculiar condition known as urethral fever and hysteria. He draws the following conclusion from his study as regards the operation:

> 1. The clinical importance of recognizing the three forms of anuria—obstructive, reflex and non-obstructive—is to be emphasized. 2. The imperative necessity of surgical interference in the obstructive and reflex forms, and its possible value in the non-obstructive cases. 3. That in the first two varieties, at least, a rapid nephrotomy on the side of pain, tenderness, and muscular rigidity is the operation of choice. If necessary, do not hesitate to make a double nephrotomy. 4. That nitrous-oxid anesthesia is probably to be preferred. 5. That time-consuming operations to relieve permanently the obstruction are to be postponed to a later period, after the patient has recovered from the anuria. 6. Operate early, by the beginning of the third day.

61. **Kidney Decapsulation.**—Johnson has experimented on fifteen dogs, of which 5 died, and gives a summary of his findings. The capsule of the normal kidney consists of two distinct layers, the outer being much the thicker, while the inner is very thin, the direct continuation of the intertubular connective tissue. In the operation of decapsulation the outer layer only is removed, leaving the inner lacerated but adherent to the kidney's surface. At first a thin exudate appears on the free surface of the kidney, which gradually becomes a fibrous investment, resembling the normal capsule in that it strips readily and becomes more and more firm with time. Microscopic examination shows this to be of varying degrees of thickness, and a homogeneous mass of fibrous tissue which will form under adhesions and can be recognized as distinct from them both macroscopically and microscopically. There is sometimes an infiltration with round cells and a proliferation of the intertubular connective tissue of the cortex, without, however, affecting the glomeruli or the general health of the dogs. Lastly and most important is that in no case was there any considerable anastomosis between the renal and perirenal blood channels. Applying these facts to operations on the human subject, he does not find that Edebohl's claim is sustained that the benefits sometimes derived from this operation are due to the establishment of a collateral circulation, but rather that they are due to relief of tension from splitting the capsule of the kidney.

64 What the von Langenbeck Operation Accomplishes in Individuals with Cleft Palate. Willard Bartlett.
65 Treatment of Verruca Plana Juvenalis, with Report of Two Cases. M. F. Engman and W. P. Loth.

62. **Hemorrhoids.**—Tuttle's article is somewhat lengthy, describing the various types of hemorrhoids and their treatment. He believes that in the varicose type of internal hemorrhoids there is a field for the injection methods. In purely internal hemorrhoids, which prolapse through a relaxed sphincter, not ulcerated, this method will frequently give us excellent results. The method, however, is tedious and may be painful. He does not use ligation, but has employed an operation of excision, adapted from the methods of various authorities. He does not advise this, however, to the general practitioner, but counsels him to hold to the old, simple efficient plan of clamp and cautery in the operative treatment of piles.

63. **The Heart in Neurasthenia.**—Norbury calls attention to the heart symptoms occurring with neurasthenia, disturbance of the rhythm, usually increased, acceleration, the Rumpf symptom, palpitation after eating and the general symptoms of heart weakness. The condition does not usually improve until the neurasthenia is well under way of convalescence. He believes in diversion as a part of the rest cure in these cases. The details are largely in regulating sleep, promoting digestion, the use of tonics, care as to the bowels and a careful consideration of nutrition in general.

70 A Late Laparotomy for Gunshot Wounds of the Intestines; Eleven Perforations; Recovery. James H. Mitchell.

66. **The Weakened Foot.**—Elting discusses the condition and its treatment and describes cases where severe cramps of the calves, pain in the knee and hip joints were experienced as also the symptom of meralgia parasthetica, which has also been attributed to this condition by Pal.

67. **Ocean Traveling.**—The advantages of ocean traveling for invalids are discussed by Hall, who also points out the drawbacks and insists on good judgment in the careful selection of cases to be benefited in this way. The same problems arise as regards land traveling. He thinks it is best not to be too ready to prescribe traveling for a patient because he has the means.

68. **Mental Wards in General Hospitals.**—The first report of Pavilion F. of the Albany Hospital is given by Mosher, who shows a total of 174 cases treated, with 57 recoveries and 53 improved. He finds many advantages in the plan of having a mental ward attached to a general hospital, though it is unsuited for a certain proportion of cases. The principle, he says, may be stated that any patient whose case may be regarded as curable by the means at hand should share the advantages of this style of ward. He speaks highly of the benefit of putting the male wards in charge of female trained nurses.

77 The General Practitioner and His Surgery. W. C. Bowers.

71. **Hemorrhoids.**—Pennington describes his operation. It consists in cutting out a section of the mucous membrane covering the pile and removing angiomatous tissue, treating each quadrant of the anus in regular order. A stream of hot sterilized salt solution (115 to 125 F.) flows over the parts continuously during the operation. Spurting vessels, if any, are caught with forceps and thoroughly twisted and, if necessary, ligated. All external tumors and tabs of skin are cut off, care being taken not to make any incision in the muco-cutaneous junction. The field is then dusted with some antiseptic powder and dressed in an extended posture by means of a rubber-covered tampon introduced through a bi-valve speculum, which protrudes about 1.5 inches beyond the anal orifice. Gauze is carefully wrapped around the protruding portion and the whole confined with a T-bandage. The patient is placed in bed and given a hypodermic of morphin, if not contraindicated, and at the end of forty-eight hours is given a cathartic and the tampon removed. From this time on until convalescence is well established, the parts should be washed or irrigated daily with an antiseptic solution, dusted with some antiseptic powder, or sterilized vaselin applied. The bowel should be kept soft for two or three weeks, and wet cotton or cottonoid used as a detergent. He finds this one of the best and most reliable operative methods.

72.—This article is practically the same as that published in The Journal, xxxix, p. 244.

73.—This article appeared in The Journal, Aug. 23, 1902.

April.

78 *Neurasthenia in Relation to the Abdominal Diseases of Women. Henry E. Leake.
79 *A Study of Nature's Method for the Cure of Asiatic Cholera. W. B. McLaughlin.

78. **Neurasthenia in Women.**—Leake objects to the reflex theories of neurasthenia, holding that they have been largely overdone. Men's minds have been unduly strained in this direction. The nervous and physical weaknesses so often accompanying abdominal disease in women is not true neurasthenia or strictly pelvic reflexes. He mentions especially, as one of the most intractable symptoms in neurasthenic women, mucomembranous colitis, which is so common that he invariably assumes it to be present in some degree. His experience with it has been large, but not always satisfactory. He protests against the prevailing indiscriminate operations in abdominal conditions.

79. **Asiatic Cholera.**—McLaughlin considers the cholera germ especially sensitive to heat, and believes that Nature attempts to rid the organism of it by vomiting and purgation. If she can not accomplish this by these alone she raises the bodily temperature to a point that interferes with or inhibits its growth. These processes, however, are a severe tax on the vitality, and the febrile process once started may refuse to be controlled, and the patient dies of hyperpyrexia. In McLaughlin's opinion, heat in cholera is an analogue of Behring's antitoxin in diphtheria. Thus he reasons that by causing an early rise of temperature in cholera patients we also lower the mortality. He reports the results of the use of normal salt solution at 112, injecting above the sigmoid flexure in five cases. The first case was moribund at the time and died, the second died within ten hours of hyperpyrexia. After this the temperature of the injection was reduced from 112 to 110 and an ice bag applied to the patient's head during its administration. The three remaining cases made good recoveries, entering the stage of reaction in each case within an hour of the administration of the injection. Illness compelled him to leave the Philippines at this time, and he has had no opportunity to give the method a further trial.

11 The Physiological Laboratory of McGill University, Montreal W S Morrow

1 **Diagnosis of Pregnancy.**—Griffith calls attention to what he considers the leading points in the diagnosis, which are, first, amenorrhea, which is sudden and not gradual in appearance, development of the breasts and their marked activity, enlargement of the uterus reaching above the pubis, allowing one half inch for each completed month of pregnancy The fetal heart beat, of course, is conclusive, but it must be sought for according to the position of the fetus

2. **Recurrent Abortion.**—What Taylor calls recurrent abortion includes only those cases where from the beginning or some definite epoch the patient has aborted with every succeeding pregnancy, and in his own usage here, with one exception, he has restricted it to cases of initial or primary recurrent abortion, that is, the patients have never had a living child Syphilis is undoubtedly the principal cause, but there are other rare ones, such as those due to intraperitoneal adhesions, especially associated with chronic appendicitis Most intraperitoneal adhesions involving the uterus either stretch or give way or are put up with by the growing organ, but some will not allow of this, and especially those graver ones which fix the cecum and appendix to the right appendages and uterus There comes a time when the uterus can not enlarge further without starting fresh and sometimes fatal mischief, and then the uterus either empties itself or peritonitis occurs, or both abortion and peritonitis may occur simultaneously Another occasional cause of recurrent abortion is deep cervical laceration, and, of course, the criminal cases must be remembered He especially speaks here of a class of cases of nearly equal importance to those belonging to syphilis where the distinguishing features are the indications of a low vitality on the part of the mother or father, or both parents, a "strumous" family history, and what he may call the remarkable result of an essentially anti strumous" treatment when carried on for a long period of time or throughout the whole of the pregnancy He tabulates twelve cases of this class, in the majority of which there is a fairly clear history of "strumous" disease on one or both sides He treated these cases with compound syrup of phosphates, 1 dram, three times a day, and increasing doses of cod liver oil, 1 dram to one half ounce, during the whole time, also the use of viburnum, and succeeded in several of his cases in carrying a child to term In conclusion he

mentions syphilitic abortions and their difference from the type just mentioned. In the syphilitic class the tendency is an upward one, each succeeding abortion is at a later period of pregnancy and finally the child is carried to term. A dead child is usually born, but finally a living one may be expected. Secondly, the clinical history of the miscarriages themselves is different. There is almost always some difficulty connected with them, retention of products, sepsis, etc. There is also a difference in the general character of the abortion, a thicker, larger and fleshier placenta, etc. In cases where he has succeeded in carrying the child to term in the "strumous" type the children have been healthy, and he is inclined to attach a different importance to defective vitality of the mother in these cases. Everything that tends to improve her health and that of the child, including the persistent administration of lime salts and easily digested fats, is of the utmost importance.

3. **Puerperal Eclampsia.**—Helme discusses the theories of eclampsia and its treatment. He has lately employed for emptying the uterus Bossi's dilator, which, he thinks, is a powerful instrument and, if used with care, is safe and effective. He asks the advisability of ending pregnancy when convulsions occur and if the existence of pregnancy is not a vital factor in the production of eclampsia and its cessation an important feature of treatment. Another question is in regard to the wisdom of large doses of morphin hypodermically. The present day practice seems to be to administer morphin in nephritis where there is not too much destruction of renal epithelium, as in the acute forms, but to withhold it where degeneration has advanced. Does not the same apply to eclampsia?

19 A Case of Goiter in an Abnormal Thyroid Gland. Harold S. Barwell.

12. **Infective Endocarditis.**—Glynn divides infective endocarditis, according to the facts thus far ascertained, into two principal classes: 1. Rheumatic, due to the specific organisms of rheumatism, and 2, septic, due to pyococci. In the former, according to Litten, the temperature may be high or low, the spleen enlarged, the urine gives the diazo reaction and petechial and retinal hemorrhages are common, but suppurative infarcts never occur. The lesions localize themselves and tend to develop into fibrous tissue, the infective character being gradually lost. The endocarditis, though infective in origin, is not in itself infective. In malignant endocarditis, on the other hand, the lesions preserve their infective character and tend to diffuse themselves and are not associated with the development of plastic tissue, but, rather, with necrosis. He discusses the propriety of the nomenclature, holding that "malignant" would be better than "infective" for the latter class. The etiology is discussed, and in the majority he finds general debility a precursor and chlorosis and anemia often attend it. Sometimes it is difficult to decide whether they are the cause or complications. It is found that Bright's disease may predispose to infective endocarditis, and Osler has collected numerous cases preceded by pneumonia. In his own cases there was a rheumatic history in 53 per cent. of males and 71 per cent. of females. There was postmortem evidence of chronic disease of the heart in 83 per cent. of his patients, including 8.4 per cent. where the lesion was congenital. Orth goes so far as to say that infective endocarditis does not develop on sound valves.

13. **Mastoid Suppuration.**—Ballance discusses the treatment and advocates radical measures. The ideal plan would involve in one operation all the following details: 1. Complete removal of the disease; 2, fastening of flap from the membranous meatus without causing deformity of the concha; 3, the epithelial grafting of the inner and outer surfaces of the operation cavity; and 4, the complete suture of the mastoid wound—the subsequent after-treatment being carried out by dry gauze tamponing through the meatus. All this, however, is rather impracticable, and an attempt to do too much is to be deprecated. Each step should be done thoroughly before proceeding to another. The plan of treatment which he practices is carried out in three stages; in the first stage of the operation he uses the gouge and burr for the bone operation. In dealing with the membranous meatus the flap is fashioned out of the meatus alone. The cartilage is removed from the flap, the flap is sutured to the raw surface of the mastoid flap with gossamer silkworm gut, which can be removed at the second operation. He finds when the burr is used the patients are less prone to sickness than when the gouge and chisel alone are employed. One week after the first operation the epithelial grafting operation is performed. A few days later, the earlier the better, removal of the dead portion of the graft is done and dry gauze tamponing through the meatus kept up until the gauze comes away unstained. He finds in from five to six weeks from the first operation in the majority of cases the cavity is soundly healed.

15. **Hypnotics.**—Tirard calls attention to the use of various hypnotics, even the mildest having their bad effects. His conviction is that, in the employment and selection of hypnotics, sleeplessness is the least important factor to be considered. The cause must be ascertained and the possibility of idiosyncrasy. The coexistence of other diseases must influence the selection of hypnotics. The risks of repeating moderate doses must be borne in mind. Generally the dose has to be gradually increased, but with some drugs like sulphonal, trional and tetronal, the danger appears to lie in the total quantity taken, though each dose may have been small. The greatest danger, however, is, when patients are given prescriptions for hypnotics, in the risk of setting up a drug habit. In this they are analogous to alcohol. He is in favor of any step that would tend to prevent their administration except under medical advice or under the physician's immediate directions. He would allow them to be dispensed only by a specially dated prescription, which would be retained by the druggist or returned to the prescriber, or would prohibit their sale to the public altogether.

16. **Puerperal Pyemia.**—Michels reports a case in which there was a postpartum fever, while the local condition of the pelvic organs was improved. There was a fulness indicating trouble in the left inguinal region, first attributed to fecal accumulation, but it remained unaltered in spite of thorough evacuation of the bowels. It increased and became slightly tender and the possibility of thrombosis of the ovarian veins was suggested. Later the patient had rigors and high temperature. Operation was performed, revealing a considerably thickened and dilated ovarian vein, which was ligated in two places, and the vein was then slit open and a fetid mass of softened thrombus was removed from its interior and small accumulations of pus evacuated. The effect was immediate. The patient rapidly improved and had an uninterrupted recovery. He says while one case is of very little value, it is suggestive and worthy of reporting in this instance.

36. **Femoro-Patellar Osteoplastic Amputation.**—Bussière has modified somewhat Gritti's original technic to avoid retraction of the muscles and fixation of the patella in a bad position. He preserves the tendons and the tendon processes and also the tendons of the thigh inserted on the tibia. He also sutures the patellar ligament to the tendons or muscles of the posterior region of the thigh with a U suture. The tendon processes and remaining portions of the fibrous or aponeurosis tissues are sutured to fill up the spaces left in cutting the stump. Silver wire is also used to ensure the fixation of the patella to the femur, by two lateral sutures By this method of amputating the stump is strong and movable. One of his patients, operated on in 1899, can be hit a violent blow on the end of the stump without experiencing the slightest pain. The stump does not become emaciated, and there is no retraction of muscles or tendons. He illustrates the various steps of the intervention and the aspect of the stump.

38. **Combination of Autoplastic Operations and Prothesis for the Face.**—In the case described the conditions resulting from having part of the jaws and tongue shot away at close contact two years before were remedied, 1, by resection of the deformed stump of the lower jaw and appropriate prothesis, and 2, by correction of the functional troubles resulting from the adhesion of the stump of the tongue to the roof of the mouth. This was finally accomplished by progressive stretching of the cicatrix by heavy apparatus. 3. By correction of the prognathism of the upper jaw, accomplished by retropulsion of the median fragment after liberal unilateral osteotomy. A slanting strip of bone, 15 millimeters wide, comprising the two premolars, was resected. This liberated the median fragment and rendered retropulsion possible. a new procedure in such cases. The results of the three-fold intervention have been very satisfactory.

42. **Pancreas in Cirrhosis of Liver.**—Klippel is convinced that cirrhosis in the liver is merely one manifestation of an affection which in fact primarily involves, at the same time as the liver, the gastrointestinal glands, the spleen and the pancreas. In some of the eight cases that came to autopsy he found the pancreas even more profoundly affected than the liver, while in others both organs seemed to participate in equal degree in the morbid process.

46. **Articulomotor Nerves of the Limbs.**—Grasset reviews the three-fold action of these nerves on the muscles, contracting, stretching and holding them, and argues that they should be designated differently from the titles now in vogue. Instead of naming them by their topographic arrangement at the periphery they should be grouped into functional units with their cortical centers. We should not call them spinal and cranial nerves as all are cranial. The brain, the cerebellum and the spinal cord should not be studied separately, but, instead, we should speak of and study the ten great nervous apparatus of the body: 1, the nerve apparatus of thought; 2, the general sensory-motor nerve apparatus; 3, the nerve apparatus of orientation and equilibrium; 4, of language; 5 to 8, of the special senses; 9, of circulation, secretion and nutrition, and 10, of digestion and respiration.

48. **Juxtalaryngeal Abscesses.**—The larynx, like the epigastric region, the utero-ovarian and the perineoscrotal, is an important reflex-generating zone. Exploration and attempts to operate are liable to induce fatal syncope, especially in case of a juxtalaryngeal abscess. It may run a latent course, with no signs of tumefaction, redness or fluctuation. Dyspnea and stridor are no positive evidence of pus, as they may be due to the underlying laryngitis. If syncope occurs when the abscess is being explored or incised, no time should be lost, but tracheotomy should be done at once and artificial respiration commenced, as otherwise the reflex inhibitory action on the heart and respiration centers may prove rapidly fatal. Seven cases are reported.

49. **Splitting of the Second Sound of the Heart.**—Cuffer calls attention to the importance of the constant or transient breaking up into two sounds of the second heart sound, corresponding to the hypertension of the systemic circulation. He regards it as an early sign of the stage of infectious diseases just preceding the establishment of lesions.

50. **"Antitoxin" Treatment of Tuberculosis.**—Guerder reasons that beside the products of bacterial origin, which successfully induce immunity when subjects are vaccinated with them, there must be other substances, likewise derived from organic living cells, possessed of the same or similar properties. They probably will not prove so powerful as those of direct bacterial origin, but still sufficiently so to answer the purpose. He has been seeking for such a substance, and believes that he has found it in cod liver oil. This is the product of the living cells of the cod's liver, and he has established that when injected into the heart of an external tuberculous lesion it annuls the inhibiting effect previously exerted by the tubercle bacilli on phagocytosis. The general beneficial effect of these local injections of the active principles elaborated by the cod liver cells is most remarkable, he states. It is partially direct but mostly indirect and consecutive to its local action. Subcutaneous injection of cod liver oil in and around a fresh tuberculous lesion may induce it to heal without leaving a trace. In tuberculous affections of the joints it renders immobilization unnecessary, and it has cured many desperate cases in which the patient was in advanced cachexia. He reports 60 cases in which he has applied this "antitoxin" treatment, as he calls it. One patient succumbed to the results of amputation, another to diabetic gangrene, and one to albuminuria, a total of 4 deaths. As 18 are still under treatment, he can make a definite report of only 42 cases. Omitting the 2 deaths from complications, his record is now 40 cured in 42 cases. The affection was a non-suppurating osteitis in 8, coxalgia in 7, enlarged ganglia in 2, and anal or cutaneous tuberculosis in 2 each. Of the suppurating lesions there were 10 of osteitis and osteoarthritis, 4 of coxalgia and 5 of ganglionary lesions. He injected 1 or 2 gm. every fourth or fifth day in the immediate vicinity of the lesion or into the fistula. The fistulas are hardest to cure, and he has found it necessary sometimes to fill them with the oil every day, injecting it into the vicinity about once a week. In a suppurating lesion it usually induces the formation of an abscess which requires evacuation, after

which the healing proceeds rapidly. The mode of action of the injections is singularly like that of a natural, spontaneous healing process as observed in the healthy cells immediately surrounding the lesion.

52. **Phenomenon of Recall.**—Rueff remarks that a lesion of the nerve centers hitherto compensated or latent, with or without previous manifestations, may suddenly become manifest on the occasion of some disturbance in the local cellular nutrition. The manifestations that follow may be a minute reproduction of some previous clinical syndrome, or they may assume a form showing that they are merely the external realization of some idea or psychic image evolved during the first manifestation of the lesion, retained in the brain during the interim and, when realized, usually becoming the starting point for a new series of morbid phenomena. The communication issues from Bernheim's clinic at Nancy.

56. **Certain Causes of Coughs and Coryza.**—Instead of ascribing to "nervousness" certain coughs and colds of obscure origin, Rosenfeld thinks we could determine and remove the cause by seeking for it. In some cases he describes the conditions always coincided with the blossoming of plane trees, and in another with the care of a parrot. He gives a view of the feather dust from the parrot, under the microscope, which well shows its irritating character.

59. **Immunity and Narcosis.**—Snel undertook, at Talma's suggestion, to discover whether narcosis reduced the resisting power of guinea-pigs. He found that it does so, but only for the time being. Narcosis suspends immunity and annihilates or temporarily suspends the saving normal bactericidal powers. These findings explain post-operative pneumonia. The narcosis annuls for the time being the bactericidal properties of the normal lungs, and the bacteria in them are thus enabled to exert their pathogenic power. During an operation, also, bacteria are more liable to be inhaled than under ordinary circumstances As the mucosa is not sensitive, coughing is not induced which would expel the saliva, mucus, etc., flowing into the throat. The surgeon, therefore, should assume the responsibility of disinfecting the mouth and throat as scrupulously as the field of operation before undertaking any surgical intervention requiring narcosis. The air to be breathed during the operation should also be as germ-free as possible, especially in case of a tracheotomy. A contrivance to filter the air as it enters the tracheal canula might ward off threatening complications from this source.

60. **Mercury Not a Factor in Tabes.**—In 86 male patients with tabes at Mendel's polyclinic 61 had a history of venereal ulcers, but only 23 had received mercurial treatment of any kind. In 31 female patients only 5 had ever been treated with mercury. The syphilitic infection had been mild or even latent in all cases.

63. **The Campaign Against Tuberculosis.**—Behring asserts that he has not yet attempted on man any therapeutic measures along the line of his immunization of cattle, and thinks that probably a long time will elapse before he can proceed to anything of the kind. He found that a hypersusceptibility to intravenous injection of tubercle bacilli on the part of the cattle, always coincided with agglutinating properties in the blood. He believes that the same parallelism would be observed in case of tuberculin if it were injected into a vein, as described in the last two issues of The Journal, pp. 1083 and 1178. He thinks that there must be some causal relation between these three phenomena, the agglutinating power of the blood, the hypersensibility to intravenous injection of tubercle bacilli and the reaction to tuberculin. If this assumption be confirmed, then it corroborates Koch's idea that the agglutinating property is an index of the resisting powers of the organism, and would apply also to the susceptibility to tuberculin. It is important, however, Behring remarks, not to confound the diagnostic and prognostic significance of the tuberculin test. The prospect of immunizing human beings by feeding infants with milk from immunized cows is sustained by his experiences with young calves suckled by immunized cows. Recently, for instance, a sucking calf, 14 days old, was vaccinated by his method and no appreciable reaction followed. Other facts that sustain his views are: 1, that several of the immunized cattle kept in infected herds for a year and a half after they had been vaccinated showed no signs of tuberculosis when slaughtered; 2, large numbers of immunized cattle have been slaughtered on stock farms and none has shown signs of tuberculosis; 3, tuberculin tests of 3 immunized cattle one year after vaccination resulted negatively when all the other cattle in the herd reacted positively, and 4, his experiences have been brilliantly corroborated by the results of Thomassen's successful experiments at Utrecht. Behring, in conclusion, qualifies all that has been hitherto accomplished in the campaign against tuberculosis, the sanatoriums, etc., as merely palliative, minor measures, no matter on how extensive a scale they may be organized, even Germany's 57 sanatoriums in active operation, with 27 on the verge of completion, and 4 seaside convalescent homes. The sanatorium movement has accomplished much good, but he proclaims that still more would be realized by isolation of the incurables. The world owes the rarity of leprosy at the present day to the policy of isolating the lepers enforced during the Middle Ages. Model dwelling houses and the strictest hygiene will not prevent tuberculosis infection so long as persons with "open" tuberculosis are housed under the same roof—or, at least, this has been his experience with cattle. Adults are not so much exposed to infection, but newborn infants are so exposed and unprotected that he does not believe it is possible for an infant to avoid infection if kept in a room with a coughing consumptive. He is confident that the young are born free from tuberculosis, but acquire it from tuberculous parents, grandparents or others. He has found that three months may elapse after a calf has been infected before it reacts to tuberculin, while years may pass before clinical manifestations become evident, if they ever do. He has noticed that circumstances depressing the vitality of the cattle were always necessary for the transformation of an animal, merely shown to be infected by the tuberculin test, into a phthisical animal. Cornet, fourteen years ago, demonstrated that the mucous membrane might allow the passage of tubercle bacilli without a local lesion. In harmony with this fact is Behring's experience that in young cattle tuberculosis infection is almost without exception localized in the abdomen, but not in the intestines; it is rather a primary tuberculosis of the glands. He announces that his laboratory research on the immunization of cattle is now at an end, as he has accomplished what he sought. The results have been so invariably successful with animals that he asks: "Shall we not do as much for our children?"

65. **Carcinoma and Diabetes.**—Boas states that there are 6 cases on record in which the patient died in diabetic coma soon after an operation for the removal of a cancer, although for several months or years previously he had been entirely free from sugar. Israel has published 5 cases of carcinoma of the breast in diabetics successfully operated on. In Boas' experi-

ence he has encountered 7 diabetics in 55 patients with carcinoma of the rectum; 2 diabetics with carcinoma of esophagus, and 2 with gastric carcinoma, and 1 of the liver and omentum. All were men. This is a total of 12 cases of carcinoma in diabetics in his total of 366 cases of intestinal carcinoma. In one case an easily operable carcinoma of the rectum in a diabetic, with some sugar and acetone, was extirpated and the patient died in coma three days later. A latent diabetes, he finds, may remain latent after an operation or it may flare up into a fatal coma.

70. **Influenza.**—Stekel is convinced that quinin has an almost specific action in influenza, and has known two doses of a gram each of quinin sulphate completely abort an established attack in the first hours. He usually gives .5 gm. of quinin hydrochlorate or sulphate, repeated in half an hour and once more after the same interval, three doses in all. For children under 6 he gives the quinin tan., as many decigrams as the child is years old, two doses. If he does not see the patient until the second or third day, he refrains entirely from quinin medication, as it is seldom effective at this stage. When there is violent frontal sinus headache he gives a combination of .01 gm. morphin hydrochlorate and .5 gm. each of antipyrin and sodium salicylate. Patients must stay in bed until the heart and pulse are normal. in case of influenza. In some instances the influenza assumes a latent or abortive form, but with marked depression, suggesting neurasthenia. One of his patients, after a five-day attack of influenza, was tormented by ideas of suicide for eight weeks, with no cause except the preceding influenza. In these cases the influenza toxins must be eliminated as completely as possible. The influenza bacillus aggravates the action of measles and scarlet fever, but, on the other hand, seems to be antagonistic to certain other infections, possibly the diphtheria bacillus. In one case a patient with gonorrheal cystitis found himself cured after an intercurrent attack of influenza. He suggests that possibly the lesser mortality from diphtheria in late years may be due to the influence of la grippe.

74. **Eczema of the Leg.**—Behrmann advocates open treatment of eczema of the leg with removal of the cause, which may be excessive walking or standing. genu valgum or pes varus, as indirect causes, and hyperidrosis, dilatation of the veins and trauma as the direct. He describes a case in detail to demonstrate the benefits to be derived from staying in bed and refraining from dressings of any kind, merely applying a salve from time to time, zinc at first and later tar. The eczema rapidly healed under this open treatment, and to prevent recurrence the patient wore a tricot stocking leg thereafter. The tricot supplied an imitation of the natural tonus of the parts and kept the pathologic tendency under control. It was left off at night. Behrmann has been very successful with this mode of treatment. He calls attention to the frequency of eczema in persons exposed to tuberculosis.

78. **Intravenous Therapy.**—Patella's article reviews the history and experiences to date of this method of therapeutics, which the Italians have most exploited. Remarkably favorable results have been obtained in threatening general anthrax infection from intravenous injections of sublimate. Corseri saved a woman of 50 stated to be already in extremis; 12 and 10 mg. of sublimate were injected in this case. Experimental intravenous injection of sublimate does not protect against anthrax infection, and intravenous injection of carbolic acid in tetanus, which has been effective in the clinic, is likewise powerless in the laboratory. This is possibly owing to the fact that experimental tetanus is always stormy and rapid, never subacute and gradual, as in the clinical cases benefited by the injections. Colloid silver is most effective in intravenous injection. Patella has tried Landerer's cinnamic acid treatment of tuberculosis by the intravenous route, but derived no benefit from it although his experience confirmed its absolute harmlessness. This was also established in regard to sodium cacodylate and the iodo-iodid solution. Spolverini has obtained wonderful results from the latter in numerous cases of tuberculosis in children, severe rheumatism and tertiary lues, without any local drawbacks. Patella has successfully injected diphtheria serum by way of the veins and also Sclavo's serum in a severe case of anthrax bacteriemia. Kramitzki has reported that intravenous injection of a filtered and diluted warm emulsion of rabies toxin is not only harmless but rapidly renders the animals immune. Silvestri has recently proclaimed that intravenous injection of calcium chlorid is among the most powerful hemostatic measures known. Patella's experience with intravenous injection of iron has not been favorable. In his tests of intravenous injections of sublimate on healthy persons he noted a considerable leucocytosis which lasted for thirty-six hours, thus mobilizing the elements most effective for the struggle with an invading affection. The intravenous sublimate injections were first used for syphilis, and recent writers have reported excellent effects from them in syphilis of the eyes. Renault has cured cases of lues of the central nervous system with the cyanid, which he has also found effective in tabic crises. Tommasoli's success in aborting syphilis by intravenous mercurial injections has been described in these columns. Patella has applied the sublimate injections in 9 cases of articular rheumatism. In one very severe case, rebellious to sodium salicylate, 2 mg. were injected the first day and 2 mg. morning and evening on the four following days. All the severe general and local symptoms entirely vanished after the third injection. The injected vein was indurated after the second injection, but this soon passed away. In 4 other cases, one also rebellious to the salicylate, the results were equally striking. Each injection was followed by a profuse sweat. In another case a man of 32 had a very painful, recurring articular rheumatism. The leucocytes increased from 9,000 to 12,200 after the first injection and general improvement was apparent. The patient refused further injections and returned to the salicylate with recurrence of the symptoms. He allowed later an intravenous injection of 3 mg. of sublimate and improved so rapidly that he could get up in three days. Patella believes that the success of intravenous injection of sublimate depends on the leucocytosis induced. If this is not produced by the first injection, little benefit may be anticipated from continuing in such cases. The intravenous route should not be chosen for general use, but in urgent cases it may prove an invaluable resource, especially in those rebellious to medication by other methods Intravenous injections are painless. If thrombi develop they are certainly due to defective technic.

81. **Is Diphtheria Serum Effective in Other Diseases?**—Hirsch has derived great benefit from it in cases of eczema, enlarged glands and prurigo, as he describes in detail.

86. **Colpeurysis for Incarcerated Gravid Uterus.**—Albert expatiates on the great value of the colpeurynter in case of a retroflexed gravid uterus. He uses it exclusively and has always cured the condition without the slightest trouble. The uterus is gently lifted, as on a cushion, without injury to it or to its contents. In one of his 5 cases the uterus had been incarcerated for three weeks, but was replaced in normal position in two hours by the colpeurynter. If the pregnancy has not passed the fourth month he usually inserts a pessary. After this stage it is not necessary. Lying on the side or abdomen and frequently emptying the bladder will prevent recurrence. He urges the importance of catheterization of the bladder as a routine diagnostic measure in all cases suggesting this condition.

93. **Influenza Prophylaxis.**—Ebstein insists on the necessity of scrupulous cleanliness to prevent infection of others in case of influenza. The "walking" cases are much more dangerous in this respect than the severe ones in which the subjects stay in bed under proper care. The same prophylactic measures as for tuberculosis should be applied to the sputa. He prefers tonics in treatment, with quinin, although he does not think there is any specific for it. Persons should not visit friends with influenza. The article is a comprehensive historical and bacteriologic study.

94. **Operative Treatment of Uterine Carcinoma.**—Klein reviews the statistics that have been published to date and deplores that even the best show that only 13.4 per cent. of the patients are permanently cured. The remedy lies in earlier diagnosis. He proclaims that it were better to curette 100 women unnecessarily than allow one woman to succumb to cancer from neglect of curetting. He hails the woman physician as the solution of part of the problem, as he thinks women will allow examination by another woman more promptly than by a man, and not postpone it until too late. He urges stricter regulations against charlatans so that time will not be wasted on them. If women consult the physician earlier, and if they are carefully examined, if necessary with exploratory incision and curette, there is no doubt that the proportion of permanent cures will be much increased.

96. **Treatment of Laryngeal Stenosis.**—Trumpp illustrates the elastic tubes he uses for intubation. They are made as if with a deep spiral screw thread, which imparts great elasticity.

98. **Regeneration of the Blood.**—Schmidt proclaims that basophile granulations and polychromatophilia usually appear during convalescence from anemia, at a time when the general health is improving. This is true not only of toxic but also of traumatic anemia, due to loss of blood. The results of experiments with rabbits also all point to the same thing, namely, that the basophile granules are derived from nuclei and are thus a sign of regeneration of the blood, and that polychromasia of the red corpuscles results from the mixing of the dissolved substance of the nuclei with the hemoglobin, whether this dissolving occurs directly in the nuclei or a stage of basophilous granulation intervenes. Both the basophile granulated and the polychromatic reds are young forms of blood corpuscles and are thus a sign of regeneration of the blood. In a case he had occasion recently to examine, the blood was normal on the day of a severe accident entailing profuse loss of blood to absolute pulselessness. On the sixth day afterward polychromatic and basophile granulated red corpuscles were numerous and remained so for three weeks. An increase in the hemoglobin of 50 to 75 per cent. paralleled these signs of regeneration.

99. **Eosinophilia with Hydatid Cysts.**—Sabrazès investigated the blood of 7 patients with hydatid cysts and found that the echinococci have a remarkable positive chemotactic attraction for the eosinophiles. In one case the eosinophiles had penetrated into the cyst, and also surrounded it with a concentric layer nearly 1 cm. thick. The almost exclusive presence of eosinophiles in the cyst fluid suggested the diagnosis, confirmed by the operation. The leucocytosis was 11,160 and 15,500 in the cases of large cysts in the liver, and was 17,360 with multiple cysts in the abdomen. The eosinophiles were prominent in every case, and usually nine or ten times the physiologic average. If the membrane of the cyst is partially degenerated the eosinophiles penetrate into the cyst and, associated with Charcot-Leyden crystals, serve to differentiate the lesion.

100. **Differentiation of Gastric Ulcer by Percussion.**—Mendel states that lightly tapping the epigastrium with the percussion hammer is not painful to anyone under normal conditions, but in case of an ulcer, a certain region, usually circular in outline, is found to be extremely painful when tapped. It is surprising how rapidly this circular sensitive area diminishes in size when proper treatment is instituted. As this can not be due to the healing of the ulcer in so brief a time, it is probably to be explained by the subsidence of the surrounding zone of inflammation as the stomach is rested. It is possible by this percussion not only to differentiate a gastric ulcer wherever located, but also to supervise its healing and be able to tell with precision when the last trace of it has disappeared. The same measure and deductions apply in the same way to ulcer in the duodenum. In every case of duodenal ulcer a sharply circumscribed painful area will be found by this percussion on the right, close to the linea alba, somewhat below the center of a line from the costal arch to the umbilicus. It is generally about the size of a half dollar, and like the similar area in case of gastric ulcer, gradually shrinks in size and finally disappears under appropriate treatment. Other lesions in the abdomen and epigastrium will be accompanied by an area of pain on percussion, but none of the others shows such a sharply circumscribed sensitive area as ulcers in the stomach and duodenum. The percussion never caused the slightest harm, but in case of a recent hemorrhage caution would be advisable. The area of pain does not necessarily locate the ulcer, but it always occurs at the same place.

102. **Importance of Nose Breathing.**—Trautmann reports a case in which the operative restoration of nose breathing was followed by the spontaneous cure of severe and previously intractable throat lesions. He warns against curetting and other destructive measures on the nasal passages, as they deprive the nose of its natural protective properties and render it as defenseless as the passages below.

110 **Intestinal Peristalsis.**—From a series of experimental investigations, the methods of which are described, and from a general discussion of the literature, Simon reaches the following conclusions: 1. In the small intestine the direction of the movement is always peristaltic. There is no antiperistalsis. 2. The movement of peristalsis in the small intestine is more rapid in the upper portion than in the inferior, both in physiologic and pathologic conditions, and is slowest in the large intestine. 3. The velocity of movement varies according to the nature of the food. 4. The introduction of food into the stomach and stimulation of the rectum and small intestine are conditions that cause the phenomena of inhibition of intestinal peristalsis.

116. **Hernia of the Diaphragm.**—Hurtado's patient was a woman of 50, five months pregnant, who exhibited symptoms of acute intestinal occlusion, suggesting internal hernia. There was no fecal vomiting and the conditions were masked by preceding administration of vigorous purgatives which had failed to purge. An artificial anus was made in the cecum, which relieved the conditions, but nothing was found to explain the occlusion. Abortion followed the next day. The opening into the abdomen had been small, as the surgeon feared the effects of a laparotomy. The patient was free from symptoms after the abortion, except that an attempt to give an anesthetic, in order to explore conditions further, caused dyspnea and was abandoned. Intense pain suddenly developed in the epigastrium and left hypochondriac region, and the patient died in a few hours. The autopsy revealed traces of old pleurisy of the diaphragm, with adhesions and a perforation resulting from an old ulceration Through this hole nearly 60 cm. of the intestine, including the transverse colon, had irrupted into the thorax. Four years before she had complained of occasional attacks of dyspnea, which had gradually become less intense and less numerous, but still recurred every one to three weeks. She was unable to sleep on the left side, as this position caused dyspnea and she had also complained since this time of a constant pain in the left side at the seventh and eighth ribs, on the axillary line. Pain from this point radiated through the left lung. This pain was always most marked in the afternoon, after eating heartily or after an emotion. The present illness commenced with an exacerbation of this pain and constipation, with occasional vomiting, not fecal. No pain in abdomen. A blister was applied to the spot and vigorous purgatives given, but without benefit. Two other cases of hernia of the diaphragm are described, both traumatic, and, in conclusion, E. Fletcher Ingals' article on the subject in THE JOURNAL, xxxvi, p. 1770, is reproduced in full in Spanish.

122. **Deformed Pelves in Mexico.**—Duque de Estrada is chief of the maternity at Mexico, and reviews his extensive experience in this monograph, which is continued as an illustrated supplement throughout the year. He does not find the general type of pelvis different from that of Europe. When a pelvis is deformed it is usually the result of imperfect development, and this condition is frequent. He has never seen elsewhere, however, a contracted pelvis, such as some of the specimens he illustrates, in which the transverse diameters were unusually short but only in the lower part of the excavation. He suggests the term "infundibuliform" for this variety. He also notes that he has never found traces of rachitis in the pelves he has examined, and, in fact, he remarks, there are no clinical records of the existence of this affection in Mexico. He ascribes the deformities observed to defective development from the lack of hygiene, the sedentary and confined life of some, hard work of others, early marriages before the skeleton is formed, and certain occupations, such as making tortillas, washing, etc., followed from girlhood. The pelvis was contracted at the inlet in .58 per cent., but a contracted outlet was much more frequent.

125. **Pilocarpin in Traumatic Tetanus.**—Garcia attributes the recovery of a patient in a case of severe strychnin intoxication to his administration of pilocarpin. The symptoms were alleviated at once after the sweating and salivation induced by it. He has applied the same treatment recently in a case of intense traumatic tetanus, injecting 2 cg. of pilocarpin and administering the same amount by the mouth, supplemented by 1 gm. of sulphonal at night This was continued intermittently, the symptoms diminishing gradually and always showing a slight marked improvement after each dose of the pilocarpin, which was generally given morning and evening at first. By the thirty-third day the movements were quite normal.

136. **Food Intoxication.**—Torre has been investigating the cause of a febrile indigestion noticed in children after eating certain kinds of sweets, and thinks that it is due to the toxic action of stale eggs.

138. **Paratyphoid Fever.**—Agramonte reports that paratyphoid fever occurs in Cuba and that the clinical picture is identical with that of typhoid fever except for the absence of sero-reaction and the results of cultures. Typhoid fever, therefore, he remarks, is not a specific entity, as other bacilli besides Eberth's are able to produce it. In the case he describes in detail he is inclined to admit a double infection, true typhoid with the paratyphoid. The first two weeks the symptoms were those of ordinary typhoid, but from the seventeenth to the twenty-fourth day there was marked intermittency in the temperature, with a difference of several degrees between the morning and evening. Repeated examination of the blood for malaria was always negative and there were no signs of endocarditis. The sero-reaction was very faint, but agglutination with Gaertner's bacillus was pronounced, and one of the two paratyphoid bacilli isolated from the feces resembled this bacillus. He reviews the history of paratyphoid, and notes that the intermittent character of the temperature after the twelfth or fifteenth day was noted in nearly all the 46 cases on record.

New Patents.

Patents of interest to physicians, March 31 and April 7:

724382. Tubular metal crutch. Joshua Conn, Dunkirk, N. Y.

723847. Lifter and conveyer for invalids. Priscilla W. Dohoney, Columbia, Ky.

724289. Hot water bag. John H. Holt, Washington, D. C.

724186. Electric apparatus for therapeutic work. Howard Jackson, Newton, Mass.

724014. Truss. Manuel E. Jasper, Wiarton, Ont., Can.

724034. Hemostatic forceps. Wm. L. Nuttall, Newcastle, Ky.

724125. Combined cabinet and examining or operating table. Gilbert H. Prindle, Washington, D. C.

724046. Instrument for intubation of the larynx. Frank E. Sampson, Creston, Iowa.

723929. Aural instrument. Richard M. Sahffer, Baltimore.

724215. Photochemical and electrotherapeutic apparatus. Albert E. Sterne, Indianapolis.

724808. Surgical truss. Blanchard Chamberlain, Bellefontaine, Ohio.

724812. Device for correcting facial defects. Anna C. Cloud.

724680. Inhaler. Alonzo Dow, Wooster, Ohio.

724889. Hernial forceps. John H. Kochenderfer, Galion, Ohio.

724913. Syringe nozzle. John T. Montgomery, Charleston, Ill.

724500. Truss. Alfred A. Raymond, Chicago.

724522. Vaccinating needle. Onesime Thomas, Paris.

724643. Hypodermic syringe case. Benjamin T. Winchester, Baltimore.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

The Public Service.

Navy Changes.

Changes in the Medical Corps of the Navy, week ending April 18:

Surgeon H. N. T. Harris, detached from the *Monocacy* and ordered to the *Glacier*, at Manila, P. I.

Surgeon N. H. Drake, detached from the *Solace* and ordered to the *New York*, as fleet surgeon of the Pacific Station.

Surgeon A. C. H. Russell, detached from the Naval Museum of Hygiene and Medical School, and ordered to the *Newark*, as fleet surgeon, South Atlantic Station..

Surgeon F. J. B. Cordeiro, detached from the Naval Training Station, Newport, R. I., and ordered to the *Solace*.

Surgeon G. H. Barber, detached from the *Monongahela* and ordered to the Training Station, Newport, R. I.

P. A. Surgeon C. D. Langhorne, detached from the Naval Hospital, Port Royal, S. C., and ordered to the *Monongahela*.

Marine-Hospital Changes.

Official list of the changes of station and Duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended April 16, 1903:

Assistant Surgeon-General L. L. Williams, granted leave of absence for eight days from April 11.

Surgeon Irwin Fairfax, to proceed to Washington, D. C., for special temporary duty.

Asst.-Surgeon H. C. Russell, relieved from temporary duty at the Immigration Depot, and directed to rejoin his station at Stapleton, N. Y.

Asst.-Surgeon W. C. Billings, to proceed to Quebec, Can., for duty in the office of the U. S. Commissioner of Immigration.

Asst.-Surgeon B. S. Warren, granted leave of absence for, five days from April 16.

Asst.-Surgeon A. D. Foster, to proceed to Southport, N. C., and assume temporary command of the station at that port during absence on leave of Asst.-Surgeon B. S. Warren.

A. A. Surgeon John Devereux, granted leave of absence for twenty-three days from April 2.

A. A. Surgeon A. P. McConnell, granted leave of absence for three days from April 20.

A. A. Surgeon E. F. McConnell, granted leave of absence, on account of sickness, for 30 days.

A. A. Surgeon A. W. Slaughter, granted leave of absence for six days from May 5.

A. A. Surgeon R. T. Walker, granted leave of absence for thirty days from April 8.

BOARD CONVENED.

Board convened at Washington, D. C., April 15, 1903, for the physical examination of an officer of the Revenue Cutter Service. Detail for the Board: Assistant Surgeon-General W. J. Pettus, chairman; Assistant Surgeon-General H. D. Geddings, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended April 18, 1903:

SMALLPOX—UNITED STATES.

Alabama: Mobile, April 4-11, 2 cases.

California: San Francisco, March 29-April 5, 10 cases.

Colorado: Denver, March 28-April 4, 27 cases.

Florida: April 4-11, DeSoto County, 28 cases; Duval County, Jacksonville included, 6 cases.

Georgia: Atlanta, March 4-April 15, 30 cases; Lumpkin, April 7, 6 cases.

Illinois: Belleville, April 4-11, 1 case; Chicago, March 28-April 11, 37 cases, 3 deaths; Galesburg, April 4-11, 2 cases.

Indiana: April 4-11, Evansville, 2 cases; Indianapolis, 4 cases.

Kansas: Wichita: April 4-11, 3 cases.

Louisiana: New Orleans, April 4-11, 5 cases (2 imported), 2 deaths.

Maine: Biddeford, April 4-11, 1 case.

Maryland: Baltimore, April 4-11, 1 death.

Massachusetts: April 4-11, Fall River, 1 case; Lowell, 3 cases; Northampton, 1 case.

Michigan: April 4-11, Ann Arbor, 1 case; Detroit, 7 cases; Grand Rapids, 4 cases; Port Huron, 1 case.

Mississippi: Natches, April 4-11, 1 case.

Missouri: April 5-12, Kansas City, 2 cases; St. Louis, 5 cases.

Nebraska: Omaha, April 4-11, 2 cases.

New Hampshire: April 4-11, Manchester, 7 cases; Nashua, 5 cases.

New Jersey: Newark April 4-11, 1 case.

New York: Binghamton, March 28-April 4, 1 case, imported; Buffalo, April 4-11, 2 cases; Rochester, March 31-April 14, 16 cases, 1 death.

Ohio: Dayton, April 4-11, 3 cases

Pennsylvania: Altoona, March 28-April 11, 5 cases; Butler, April 4-11, 1 case; Carbondale, March 31-April 7, 1 case; Johnstown, April 4-11, 1 case; Philadelphia, March 28-April 11, 43 cases, 7 deaths; Pittsburg, April 4-11, 29 cases (2 imported), 3 deaths; Williamsport, April 4-11, 1 case.

Tennessee: Memphis, March 28-April 11, 13 cases; Nashville, March 28-April 4, 2 cases.

Utah: Salt Lake City, March 28-April 11, 17 cases.

Wisconsin: Milwaukee, March 28-April 11, 3 cases.

SMALLPOX—FOREIGN.

Austria: Prague, March 14-28, 13 cases.

Belgium: Antwerp, March 14-21, 2 cases, 1 death; Brussels, March 14-28, 6 deaths.

Brazil: Rio de Janeiro, March 6-13, 5 deaths.

Canary Islands: Las Palmas, March 7-21, 44 cases.

Colombia: Barranquilla, March 15-22, 2 deaths.

France: Roubaix, March 1-31, 1 death.

Great Britain: Dublin, March 14-28, 33 cases, 1 death; Hebburn-on-Tyne, March 14-21, 1 case; Leeds, March 14-28, 26 cases; Liverpool, to March 28, 68 cases, 7 deaths; London, March 21-28, 5 cases; Manchester, March 21-28, 18 cases, 1 death; Newcastle-on-Tyne, March 14-21, 2 cases; Nottingham, March 7-28, 11 cases; Sheffield, March 7-21, 4 cases; Walker-on-Tyne, March 14-21, 2 cases; Wallsend-on-Tyne, March 14-21, 2 cases.

India: Bombay, March 3-17, 157 deaths; Calcutta, Feb. 28-March 14, 1 death; Madras, Feb. 28-March 6, 1 death.

Mexico: City of Mexico, March 22-29, 7 cases, 4 deaths.

Netherlands: Flushing, March 21-28, 1 case.

Russia: Moscow, March 14-21, 4 cases, 1 death; Odessa, March 14-21, 6 cases, 1 death; St. Petersburg, March 14-28, 169 cases, 9 deaths; Warsaw, March 14-21, 3 deaths.

Turkey: Alexandrette, March 14-21, 3 cases, 1 death; Constantinople, March 15-22, 1 death; Smyrna, March 1-8, 1 death.

YELLOW FEVER.

Brazil: Rio de Janeiro, March 6-13, 38 deaths.

Colombia: Panama, March 26-April 2, 4 cases, 1 death.

Ecuador: Guayaquil, March 14-21, 4 deaths.

Mexico: Vera Cruz, March 28-April 11, 12 cases, 2 deaths.

CHOLERA—INSULAR.

Philippine Islands: Provinces, Feb. 14-21, 172 cases, 117 deaths. Not previously reported, 953 cases, 736 deaths.

CHOLERA—FOREIGN.

India: Calcutta, Feb. 28-March 14, 159 deaths.

PLAGUE—INSULAR.

Philippine Islands: Manila, Feb. 14-21, 2 deaths.

PLAGUE—FOREIGN.

Brazil: Rio de Janeiro, March 6-13, 1 death.

China: Hongkong, Feb. 14-28, 15 cases, 15 deaths.

India: Bombay, March 3-17, 2,300 deaths; Calcutta, Feb. 28-March 14, 1,574 deaths; Karachi, March 8-15, 199 cases, 160 deaths.

Mexico: March 8-22, Siqueros, 3 cases, 2 deaths; *Villa Union*, 3 cases, 1 death.

The Journal of the American Medical Association

Published under the Auspices of the Board of Trustees

Vol. XL. CHICAGO, ILLINOIS, MAY 9, 1903. No 19.

Address.

MEDICAL EDUCATION IN THE UNITED STATES.

PRESIDENT'S ADDRESS, DELIVERED AT THE FIFTY-FOURTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, AT NEW ORLEANS, MAY 5-8, 1903.

FRANK BILLINGS, M.S., M.D.
CHICAGO.

One of the chief objects of the organization of the American Medical Association was the elevation of the standard of medical education in the United States. In the president's address, the Father of the Association, Dr. N. S. Davis, stated that "the purpose of the organization was the improvement of our system of medical education and the direct advancement of medical science and practice."[1] That medical education in that day was defective, as recognized by the founders of the Association, is shown by the report of the Committee on Medical Education in the year 1850. The committee said, in part, as follows: "Medical education is defective because there are too many medical schools; the teachers are too few. There are too many students. The quantity of medicine taught is too limited; the quality too superficial, and the mode of bestowal of the honors of medicine too profuse and too unrestricted."

For many years the Association showed its interest in and attempted to influence the elevation of the standard of medical education through a committee on medical education. The Transactions of the Association of the earlier years show many reports of this committee, which display much thought and effort on the part of the Association to improve the status of medical education at that period of time. James R. Wood, as chairman of the committee, in the year 1858, recommended that the various medical colleges of America be requested to send delegates to a convention of medical colleges, to consider the matter of medical education. This movement finally resulted in the formation of the Association of American Medical Colleges, which thereafter represented, to a degree at least, the American Medical Association in its efforts to improve medical education. Later, the Southern Medical College Association was formed. Together these associations represent about 80 per cent. of the regular medical schools of the country, and these colleges have, in a general way at least, fulfilled the minimum requirements prescribed by the rules of the associations in regard to the preliminary education of students, the length of the college course, and the character of the curriculum.

About twenty-five years ago the Illinois State Board of Health, through the splendid efforts of Dr. J. H. Rauch, its secretary, made a report on the number and character of the medical schools of the country. This board adopted a minimum of requirements of medical schools as a necessary step toward the recognition of their diplomas by the State Board of Health of Illinois. This minimum requirement of the State Board of Health was gradually increased from time to time, with the result that many of the medical schools were obliged to raise the standard of medical education to enable their graduates to obtain licenses to practice in Illinois. Other states followed Illinois in requirements for better methods of medical education, with the result that the standard of education in the country was very much improved.

MEDICAL SCHOOLS OF THE COUNTRY.

In the earlier days of our country, the need of physicians was met by the organization of medical schools, which were, as a rule, proprietary in character. These schools attempted the education of physicians on the then existing conditions of medicine by teaching in a didactic way the principles and theories of medicine and surgery. The branches usually taught at that time consisted of anatomy, physiology, chemistry, materia medica, obstetrics, the practice of medicine and of surgery. But little opportunity was offered in the great majority of the schools for extensive, practical teaching in anatomy or chemistry, and but a moderate amount of clinical work in the so-called practical chairs. The course of medicine in the college consisted of two annual sessions of four or five months. The course was not graded. The student attended all the lectures and clinics taught during his first year, and the second year was a repetition of the first. This class of schools was rapidly increased in the course of time. The chief reasons therefor were the fact that it was recognized that a connection with a medical school was profitable, directly and indirectly. The prestige which the teacher enjoyed among the graduates and the laity brought him a remunerative consultation and private practice. In most of the states it was easy to incorporate and obtain a charter for a medical college. It cost comparatively little to conduct and maintain the institution. Lecture rooms were obtained at trifling cost. The dissecting room was not worthy of the name of a laboratory, and the chief expense in maintaining it was the cost of dissecting material, which was usually deficient in quantity and poor in quality. Medical schools were organized all over the country, without reference to the needs of the people. Medical education was prostituted. To obtain a sufficient number of students many institutions showed a most degraded disregard of the moral and mental qualifications of the matriculates. The income of the school was wholly derived from the tuition of students, and no applicant was

APPLIED MEDICINE AND SURGERY.

To enable the student to utilize the knowledge of a thorough training in anatomy, physiology, chemistry, pharmacology, physiologic and physical chemistry, embryology, neurology and pathology, he should be afforded facilities of equal rank in clinical medicine and surgery. To supply the student with proper clinical facilities involves several important features. Special hospitals, which would be absolutely under the control of the medical school, would be necessary. The hospital should be constructed with a definite idea of teaching students and of making researches into the nature, causes and treatment of disease, as well as to care for a definite number of patients. Hospitals for general medicine, surgery and obstetrics would be essential. Such hospitals, with laboratories and equipped with instruments, apparatus and library, would cost for their building and maintenance a very large sum of money. With such hospitals it would be necessary to choose the professors of medicine, of surgery, and of obstetrics, with competent assistants, of the same type as the teacher of the fundamental sciences. They should give their whole time to the work of teaching and to original research in the hospital. They should be men who have proved their scientific fitness for the important positions by the contributions they have made to medical knowledge. They should rank with and receive the pay given to professors of important departments in arts, philosophy and science. When so paid, they would be free to expend all their energy to teaching, and to experimental medicine—a career which would enable one to be of the greatest possible service to mankind. No life's work could be fuller or of greater self-satisfaction, and surely none would be more honorable. From these teachers and investigators the student would obtain instruction of the same systematic methods of accurate observation and investigation which were employed in the fundamental branches. He would receive thorough, conscientious drill in the fundamental methods of examination of patients, and his knowledge of the fundamental sciences would be constantly applied in this work. The trained clinical teachers would direct the student in thorough, careful observation in the wards and at the operating table, would collect data to be submitted to experimental tests, and would conscientiously carry out the experiments in the laboratories of the hospital.

The brilliant discoveries which have made our knowledge of the cause and means of transmission of many of the infectious diseases have been chiefly due to the introduction of the experimental method of investigation. Teachers and investigators of the type mentioned will have the opportunity to make equally important discoveries in the broad field of the unknown in medicine. They will train students in the methods of research work and constantly increase the number of investigators in the domain of medicine. And there is need for such men. We may give the great practitioners who have taught clinical medicine their due meed of credit for their excellent, painstaking, unselfish efforts as teachers. They have added to the sum total of our clinical data, have utilized the knowledge of the pathologist and the physiologist in diagnosis, and have tested and judged the worth of therapeutic aids in the treatment of disease. But as teachers they have not made students investigators or experimenters. Not one of the recent great discoveries in medicine has been made by such a man. He has used as clinical material hundreds of cases of pneumonia, rheumatic fever, tuberculosis and chronic diseases by the score; his experience has taught him to recognize these diseases, even when the clinical manifestations are obscure, but he is no more successful than when he began to practice, in saving the life of the patient with pneumonia, in preventing endocarditis in rheumatism, in curing tuberculosis, or in checking the advance of a chronic hepatitis. It is time, therefore, that the clinical teacher should have the knowledge necessary to carry on experimental investigation, with hospital facilities for the work that the profession may become purged of the shame of helplessness in curing so many of the common diseases of mankind.

The patients who will be received in these hospitals will be fortunate. They will receive the most painstaking examination and study, and the experiments made on animals in the laboratory will benefit the patients directly, inasmuch as more rational therapeutic measures will be applied in cases so investigated. In addition to the clinical teachers, who will devote all their time to teaching and research work in the special hospitals, there will be quite as much need for the clinical teacher, who is in private practice, in the general hospitals. Under his direction the student may himself investigate a hospital or ambulatory case, and undertake the care of the patient. His rich and varied experience in hospital and private practice will enable him to round out the student's college education. He will impart to the student a better idea of medicine as a whole. He will coordinate and arrange the isolated facts of clinical and laboratory investigation, and give them their true and relative value. He will teach the student the art of medicine; he will teach him that human sympathy and encouragement of the sick and dying are a part of his duty as a physician.

It would be most practical to make the clinical work of the third year a clinical drill and experimental course, given in the special hospitals, and assign the students of the fourth year to the general hospitals and to the clinical teachers who are in private practice. All the general hospitals and dispensaries controlled by the medical schools could be utilized in the fourth year for this purpose, and afford the student an abundance of clinical material and the benefit of the experience of many clinical teachers. Many of the assistants in the special hospitals, of the third year course, would doubtless engage ultimately in private practice, and would, because of their scientific attainments, make excellent clinical teachers in the fourth year. A medical school conducted on the high plane advocated must necessarily be under the control of a university. Such a medical school would cost an enormous amount of money, and this can be commanded only by the trustees of a university of the highest order. That the money for the purpose of establishing and maintaining university medical schools with research hospitals and university clinical courses will be forthcoming can not be doubted. The world is awake to the great discoveries recently made in medicine. The wealthy men of this country have had their interest aroused as never before in reference to the possibilities and benefits which medical investigation will give to mankind. They now recognize that they and all posterity will be benefited by every new fact discovered in medicine, and that physicians thoroughly and scientifically trained are necessary to conserve the health of the people.

Three years ago Prof. W. W. Keen, in his address as President, deplored the fact that medical schools received relatively little aid in the form of endowments as compared with universities and colleges of philosophy, art and theology. Since that time several millions of dollars have been given for medical education and scientific research. The signs of the times point to a brighter future of medicine in America.

EDUCATION PRELIMINARY TO MEDICAL STUDY.

The subject of the educational requirements for matriculation in medical schools has been discussed at many meetings of this Association in its earlier years, and later by the college associations, by the American Academy of Medicine and by the various state boards of health.

The requirements were at first lamentably low, and the efforts of the Committee on Education of the American Medican Association and of the college associations had but little effect, because they possessed no legal power to control the schools.

The influence of the various boards of health of several states, notably Illinois, was more marked, inasmuch as these state boards possessed a mandatory power. The colleges were forced to adopt the minimum educational requirements of the state boards of health if their diplomas were to be recognized by the respective state boards.

These moral and legal influences to improve the preliminary requirements were almost nullified by the practice of a majority of the medical schools in admitting students whose educational status was examined into and judged by a committee of the college faculty.

This practice is still followed by a majority of the medical schools, and results in the admission of many students who are unable to fulfill the prescribed requirements. As a subterfuge, students are often matriculated conditioned in one or even several subjects. Then the student and the faculty committee forget all about the subject, and the student completes his course, goes into practice, and dies with the conditions still undischarged.

The present requirements of the college associations and of the various state medical examining boards and state boards of health amount, on the average, to a high-school education. The curricula and length of course of the high schools of the different states, and even in the same state, differ very substantially. However, if the medical schools now in existence would honestly require as a minimum education the diploma of a high school, without regard to the rank, it would be a marked advance over the present requirements as practiced by most schools.

We must admit, too, that there are medical schools of such a low educational grade that they have no right to demand of their matriculates as much even as a common school education. This fact that low-grade medical colleges exist is one of the most satisfactory explanations of the difficulty encountered in elevating the standard of preliminary requirements.

To get at the root of the matter the medical college must be brought up to the proper educational standard, and then, and then only, can be made a proper preliminary educational requirement.

UNIVERSITY MEDICAL COLLEGE.

The present status of medical science requires and demands a university medical college course. By university medical college is meant a medical school which is directly connected with and a part of a university; the university fixing the requirements and controlling the admission of students to the medical department. The method of teaching both the fundamental and the clinical branches is on the principles outlined above. To properly prepare for such a course the student should have, as a minimum preparation, at least two years of study in a good college or university. The requirements to enter a good college or university would insure a sufficient knowledge of the ordinary school branches and also Latin or Greek. During the two years' course in college his time would be well spent in the study of English, French, German, mathematics, history, philosophy, physics, chemistry, general and organic, and qualitative analysis, comparative anatomy and general biology. The amount of time to be devoted to each of these subjects would be the same as that of students of general science, as arranged in all college curricula, with the exception of a much more thorough course in chemistry, biology, physics and comparative anatomy.

So prepared, the medical matriculate would be able to grasp all the intricacies of the subjects of the fundamental branches of medicine. With the addition of the full medical college course, as outlined above, his education would be equal in culture to that of the graduate in arts and philosophy. At the same time, it would be practical and especially fit him for his work as a scientific investigator or practitioner, or for both.

With the medical profession so educated a physician would be, in truth, a member of a learned profession. From an educational point of view he would rank as an equal with the scholar in philosophy, law and theology. As a man he would be recognized as the greatest benefactor of mankind.

With the establishment of university medical schools the first two years of work in the medical school will consist of courses in pure science. Then, doubtless, all universities will adopt the plan which two or three universities have already put in practice. That is, that the student who completes the two first years of the science course of a university, or at a college of good standing, may enter the sophomore year of the university and take the first two years' work in medicine, as the sophomore and senior years of the bachelor's course, when he would receive the degree of S.B. The student who completes the three years of the arts or philosophy course at a university, during which he should take a large amount of work in physics, chemistry and biology, could then enter the medical college and after two years receive the degree of A.B. or Ph.B. After two years spent in the clinical school he would receive the degree of M.D.

This telescoping of the literary and medical courses affords the advantage of an economy of time, while it does not in any way lessen the value of the result to the student. In the one case the student secures the degrees of S.B. and M.D. after about six years of study, and in the other the degrees of A.B., or Ph.B., and the degree of M.D. at the end of seven years' study.

THE OUTLOOK OF MEDICAL EDUCATION IN THE UNITED STATES.

Medical education must advance to its proper level if it complies with the present status of the medical sciences and the demands which continued evolution in medicine promises.

What does this imply? It means that the private—the proprietary—medical school which is conducted for commercial reasons must go. Acknowledge, as we must, the great value which the best of these schools have been to the profession and to the country, all such schools have lived past the time when they can be of value. The continuation of these institutions henceforth will be harmful. They can not command the money to build, equip and maintain the laboratories and hospitals which a proper and adequate medical education demands. In the past their graduates have furnished the many great and influential medical and surgical clinicians of this country. In former days a graduate poorly prepared has been able, by indefatigable labor and post-graduate work, to place himself in the front rank as a clinical physician and surgeon.

To-day medical science demands primary instruction to fit a man as an investigator and scientific physician. If not properly educated he can not grasp the great problems which medicine presents to-day as he did the more simple clinical facts which comprised the art of medicine and surgery a few years ago. In the future medicine must be taught in the large universities of the country and in the state universities which are situated in or near large cities, where an abundance of clinical material may be commanded.

The state university and the college which desires to teach medicine, and is so situated that it can not command clinical material, should confine itself to teaching the sciences fundamental to medicine. These should be taught as pure sciences, and should be included in the course for the degree of S.B. A college or state university ambitious to teach the medical sciences can do so without great cost. To attempt to teach applied medicine without proper and adequate hospitals, and with an insufficient number of patients, would be irrational, nor can they command the necessary funds with which to do it. From such colleges and state universities the students could go to the larger institutions which are able to furnish the proper facilities for teaching applied medicine and surgery.

The general hospitals of many of the cities, now used by proprietary schools, could be utilized as clinical schools for both undergraduate and post-graduate teaching, conducted by the clinical teachers in the existing proprietary schools. Indeed, these hospitals could be utilized as university extension clinical courses. Necessarily they would have to be under the control and direction of a university medical school.

How many schools may be necessary to educate the number of doctors of medicine required annually in the United States? The question one can not answer, but it is safe to say that 2,500 graduates annually will fully supply the demand. This would imply about 10,000 to 12,000 matriculates. A minimum number of twenty-five and a maximum number of thirty-five medical schools should offer sufficient facilities to educate 10,000 students. The various state universities and the colleges which offer adequate science courses would educate a great number of students in the fundamental branches, or in the first two years of the medical course.

MEDICAL RECIPROCITY BETWEEN THE STATES OF THE UNION.

The low requirements of some medical colleges, and the want of uniformity in the requirements for a license to practice in the different states, has resulted in a condition which entails much hardship on a physician who desires to remove from one and to engage in practice in another state. The rules of most state boards of medical examination and of health are so stringent that a physician or surgeon of years of experience and of acknowledged skill and education, and the specialist who may be renowned in his field of work, are obliged, like the recent graduate, to take an examination in all of the branches of medicine and surgery in order to secure a license to practice in the state of his adoption.

To correct this evil it has been suggested by a member of the American Medical Association, and concurred in by others, that a national board of medical examiners be organized; that the board hold examinations at different seasons of the year in the various large cities, and that the diploma so obtained shall be recognized as a license to practice in any one or all of the states and territories. The measure suggested seems to be practical and feasible.

In addition to this plan, it remains to be said that the degree granted by the future university medical school will be undoubtedly recognized as an evidence of fitness to practice in any state in the Union. When we shall have a less number of schools and annual graduates the various states may safely and rationally become more liberal and discriminating in the conduct of their office.

THE INFLUENCE OF THE AMERICAN MEDICAL ASSOCIATION.

The American Medical Association should maintain its interest in the elevation of the standard of medical education, one of the chief reasons of its organization. Its influence in former years was principally moral. This was of considerable value, for the reason chiefly of the high ideals of the founders and first members of the Association, who advocated and fought for a higher standard of medical education. In the future its influence should be many fold that of the past, for with the reorganization of the profession, the better methods of conducting its affairs, the increased and probably very large membership, and its great medical journal, it should wield a great influence for good.

As the direct agent by which the American Medical Association may exert its influence in the elevation and control of medical education, the Committee on Medical Colleges and Medical Education should be made permanent and should be given adequate power and sufficient annual appropriation to make its work effective.

This Association should, therefore, stand for, and should use its whole power to improve, medical education in this country. It is said that we never exceed our ideals in practice, and that if we lower our ideals our conduct sinks to a lower level.

The American Medical Association should take as its ideal and standard of medical education the university medical college, with all the name implies in regard to the fundamental medical sciences, and to the clinical branches. It should use its influence to drive out of existence those proprietary medical schools which are conducted solely as money-making institutions. These measures can not be accomplished at once; but medical science demands it, the profession demand it, the people demand it, and look to the American Medical Association as the chief influence which shall accomplish this end.

To Whom Does a Prescription Belong?—In France it is the custom to give the prescription to the one who pays for it, according to a recent article on this subject by Carles in the *"Journ. de Méd. de Bordeaux."* The pharmacist in the cities merely keeps a copy of it and the prescription is given up with the medicine as it is paid for. In the country, the proportion of illiterate is so large that the pharmacist is always urged to keep the paper, and this is now the custom. The prescriptions are also kept when dispensed to members of benefit societies, as payment is made by the treasurer on presentation of the prescriptions. In case secrecy is desired the member can pay for his medicine out of his own pocket and thus claim the prescription. The pharmacist also keeps the prescription if he discovers that the physician signing it has made a mistake, rendering it impossible for him to dispense the medicine called for, until after consultation with the physician.

Orations.

CANCER AND IMMUNITY.

ORATION IN SURGERY, DELIVERED AT THE FIFTY-FOURTH ANNUAL MEETING OF THE AMERICAN MEDICAL ASSOCIATION, HELD AT NEW ORLEANS, MAY 5 TO 8, 1903.

A. F. JONAS, M.D.
OMAHA.

On such occasions as this we take great pleasure in recalling the past and dwell with great delight on the achievements along the lines that have most engaged our attention. We, as surgeons, especially those whose professional activity began in the pre-antiseptic period, review the successive changes from that period of expectancy to the present period of aseptic accuracy with the greatest satisfaction. No one can fully appreciate the present status of surgery who is not personally familiar with the period when wound complications were the rule and when faith was pinned on the belief in "laudable pus."

However great the change has been in surgical mortality, in the great improvement in wound repair and in the comparative freedom from wound complications at present, when we consider the number of diseases treated surgically we must confess that many problems remain unsolved. We are not prepared to say, even now, as Boyer did in his great work, Traite des Maladies Chirurgicales (1814-1822), that he believed that surgery had reached perfection. The great advances of the past have taught us the imperfections of the present and have pointed out to us the lines of research for the future.

At the outset, we are not unconscious of the fact that the profession itself is not yet agreed on many well-founded propositions. Many still cling with too much tenacity to old and deeply-rooted doctrines. Progress has been so rapid. The surgeon has, perhaps, been in advance of the physician along scientific and practical lines. The physician has observed that the surgeon has gradually invaded his field, thus creating some antagonism, but it has become less apparent and more co-operation has been the rule since bedside observation and a clearer pathology have demonstrated the actual conditions.

In this connection, we are convinced that there is still too much difference of opinion between the physician and the surgeon regarding the so-called borderland cases. In that class of affections which primarily are so-called medical, and later may become surgical, in which the early stages are obscure, where no positive diagnosis can be made, where there is no improvement from the usual internal treatment, these constitute a class where an exploratory incision would not only make a diagnosis clear, but would frequently lead to a cure.

Still, too much time is wasted in the medicinal treatment of such affections as goiter, tubercular lymph nodes, pulmonary abscesses and gangrene, empyema, abscesses and tumors of the liver, obstruction of the biliary passages, diseases of the pancreas and tubercular peritonitis. Chronic Bright's disease and ascites due to hepatic affections, always believed to be purely medical, have recently received the attention of surgeons and the success has been sufficient to give much encouragement. The foregoing constitute a class of borderland cases in which it is often impossible to state where medical management ends and where surgical treatment begins.

Surgical advancement in the future will not consist so much in the radical changes in operative technic as in improvement in diagnosis and diagnostic aids. Many of our diagnostic formulæ are even now undergoing complete changes, and the future will lead us to a precision in the recognition of disease that we little dream of now. The early recognition of malignant disease is a problem of future development, especially malignancy affecting the internal organs. With our present aids it is impossible to recognize internal cancers sufficiently early to do a radical operation. Our only course at the present is an exploratory incision as soon as reasonable grounds for malignancy exist.

The field that seems full of promise and gives us hopes for great expectations in the future is that of immunity and immunization. It now seems that many tissue changes will be solved along these lines.

From our present viewpoint the question of immunity seems to tower above and overshadow all others. It involves the greatest problems for the future investigator to solve. Out of these researches will be evolved methods for the exact treatment of that great list of surgical affections which, at present, we can fortunately, to a great measure, avoid by exact asepsis and can control, to a great extent, by antiseptic measures when once developed. But we still stand helpless in the presence of severe forms of septicemia, pyemia, tetanus and other toxic invasions. Infections sometimes occur after the most carefully executed operative procedures. Accidental infections will always comprise a large proportion of our surgical material, a group of cases that furnishes a fatality all too great.

Our present helplessness in the presence of extreme toxemia, we must confess, lies in our imperfect knowledge of the exact conditions under which the toxins operate. We may say, in a general way, that toxic bodies attack and destroy cellular elements. When, however, we study this question of infection in a more serious manner, we find that a flood of light has been thrown on this problem by Ehrlich and his followers.

The two greatest problems of the future, cancer and immunity, shall engage our attention to-day. Malignant disease seems to be on the increase. We stand so helpless in its presence when fully developed that we exert our feeble energies and grasp eagerly for any fact that seems to offer new light for its better understanding. It will be our effort at this time to review, as briefly as possible, the more important facts known regarding the etiology of cancer and then, after making clear to ourselves the revelations thus far made in the recent studies of immunity, determine, if possible, what relations, if any, exist between the two.

These considerations were prompted by personal observations made in a number of cases of undoubted malignancy that indicated the probable infectiousness of cancer. It is well known to us all that the infectiousness of most infectious diseases was first determined clinically and that the clinical observations were later determined and confirmed microscopically and experimentally. The cases to be here related came under the author's personal care, and it is hoped that they may serve as contributory evidence to the observations already recorded by others *that malignant disease, under certain conditions, is infectious.*

Case 1.—Mrs. H., aged 40, of spare build, very small amount of adipose tissue, presented in the outer and upper quadrant of the left breast a hard, nodular, painful, movable, walnut-sized growth, of one year's duration. In the axilla could be felt a hazelnut-sized nodule. She had frequent lancinating, radiating pains in the breast. There were no evidences of acute or subacute inflammatory signs, no local redness or elevation of temperature. The clinical diagnosis of cancer of the breast was made and a radical operation was advised Various family matters prevented her from submitting to an immediate operation, so that several months passed, after which it was observed that the neoplasm had diminished in size and it finally disappeared.

It may be urged that this may not have been a cancer or that no one should make a diagnosis unless there be a confirmation by the microscope. Is the microscope always certain? We have all observed cases that ran a clinical course of malignancy after the microscopic findings indicated benignancy, and vice versa. The pathologist always inquires after the clinical features. He is disinclined to give an opinion unless he can know something of the history and symptomatology. The above case, in every detail, resembled many others that were demonstrated microscopically to be malignant, consequently it would appear that we are justified in the clinical diagnosis of cancer.

Case 2.—Mrs. J., age 35, presented herself with an inoperable, extensively ulcerating carcinoma, involving the outer half of the right breast. The breast was unusually large. The outer portion of the ulcerating surface had been in constant contact with the upper and inner side of the arm. Portions from both breast and arm were removed for microscopic examination and proved to be alveolar carcinoma. No operation. She died in three months.

Case 3.—Mrs. D., age 35. She came under observation with a typical epithelioma of the cervix uteri. The vagina was large and relaxed, so that the neoplasm rested in contact with the lower portion of the posterior vaginal wall. Hysterectomy was recommended, but was refused. She presented herself again in two months, in which time there had developed an epithelioma at the point of contact between the cervical growth and the posterior vaginal wall. An operation was done, but the patient died from recurrence eight months later.

Case 4.—Mrs. G., age 45. Came under observation with a typical cauliflower growth involving the cervix uteri. Small particles were removed, which proved, microscopically, to be carcinoma. The uterus was fixed, the growth appearing to be too extensive for operative interference. No operation was advised. After several months the neoplasm became smaller and gradually disappeared, the uterus becoming movable. At the present time, eight years later, she appears well.

Here we have four cases of undoubted cancer, each one of which presented some of the features of an infection, as in lupus or syphilis. Cancer is extremely slow in its development, its premalignant stage often lasting many years. This fact possibly may account for the negative outcome of inoculative experiments hitherto conducted. This long developmental stage is not unlike lupus, leprosy and other forms of undoubted infection. In two of our cases we observed secondary growths which appeared at points where the primary neoplasm was brought, more or less continuously, in contact with previously healthy surfaces, a very common occurrence in nearly all forms of infection. In two of our cases the neoplasm disappeared spontaneously, the disappearance depending, no doubt, on some form of katabolism not yet understood. The elucidation of this form of cytomorphosis will give the key to the control, inhibition and elimination of the atypical cell proliferation which constitutes malignancy.

The term cancer, so commonly employed, refers to growths made up chiefly of epithelial cells. There is really no good reason why the term cancer should be limited to epithelial growths. Cancer signifies "crab." It was originally used to signify malignancy and meant connective tissue growths as well as those of epithelial origin. For our purpose at this time we will limit the term cancer to epithelial neoplasms and we will confine these considerations to its etiologic factors.

The mystery of its origin seems as deep almost as in the days when cellular pathology was unknown. No problem in pathology has received more thought and speculation, no subject has had bestowed on it more earnest effort and unremitting toil. Regarding its etiologic evidence we must confess that we have only a mass of negative proof. When observers believed that they had found the specific organisms, scores of workers in the same field soon demonstrated their error. So, today, we can only say that the evidence which shows what we do *not* know of the cause of cancer is voluminous, and we must admit that we know little of its etiology.

We know something of its cell characteristics. We know that malignant disease is essentially a cell proliferation that has, biologically, many features that are opposed to the physiologic tissues in which they take their origin. We find an atypical life history in the cancer cells. The nucleus divides in an asymmetrical way. We note that unusual karyokinetic figures in the nucleus are usual in new growths, pointing to changes in the cellular life history. Regarding carcinoma, certain bodies have been demonstrated, believed by some to be parasites, having some causal relation to the cell changes.

It is a well-established fact that the nucleus perpetuates the nature and function of the cell, and any change in the nucleus changes the cell in its function and process of division. According to W. V. Shaw, "the growth of cancer cells is then to be looked on as an effort of reproduction in damaged tissue, the incidence of the damage falling on the nuclear structures."[1]

This statement is based on observations made by him in connection with experiments on free swimming larvæ which developed from the stimulation of ova of certain lowly organized animals, causing a proliferation of cells. The ova had not been fertilized by spermatozoa. Adult organisms were not developed, but larvæ capable of independent life. These results were obtained by stimulating the ova with strychnia and by mechanical movements of the ova. This cell growth was compared to growth of tissue in partially damaged structures. Shaw believes that such damage alters the nature of these cell structures so that the vegetative functions of the cell run riot and the cells become parasitic toward the organism in which the growth is taking place. This view seems to find support in those connective tissue growths that develop in tissues that have sustained a trauma and in which the sarcoma develops; or in epithelial growths that form on surfaces that have been subject to prolonged irritation, as exemplified by the chimney-sweep's and paraffin-worker's cancer forming on an old chronic dermatitis; or a cancer forming on the site of a prolonged irritation by the smoker's pipestem on the lower lip. We have seen many times that cancer develops in epithelial tissue that has been subjected to irritation for a long time, usually extending over a period of years. We have long recognized irritation to be at least one of the causative factors. Just what metabolic disturbances take place and what the underlying causes are, is not yet clear. That cancer is infectious has been proven by many clinical observations. This has been shown by Eberth, who collected 22 cases where cancer was transmitted from lip to lip, tongue and palate. Behla reported eight instances of death from malignant growths in physicians and surgeons who were inoculated from tumors and four instances of apparent human infection from cancerous animals, dog and hen. He also alludes to a cancer epidemic among the white mice in the Pathological Institute at Freiburg as evidence of the contagiousness of cancer (Hektoen). Roswell Park believes that, for New York state at least, cancer is increasing at an alarming rate.

---

[1] The Lancet, Sept. 20, 1902.

Attempts have been made to show that cancer is endemic, peculiar to certain localities. Behla cites cases of Behrens, who found in a village ten deaths out of thirty-eight to be due to cancer. Pfeiffer, Powers and Friesinger maintain that in certain houses (cancer houses) and marshy districts in the vicinity of ditches and streams containing sluggish water, especially if the stagnant and polluted water were used for watering garden vegetables and for drinking purposes, cancer is relatively frequent (Hektoen). This would point rather to a microphyte than to a microzoon as the etiologic factor.

Since infection of living tissue is believed in every instance to be due to bacterial invasion, naturally bacteriologists directed their attention toward the discovery of a specific germ. Very soon we had a long list to enumerate. Plimmer of London examined in six years 1,298 carcinomata, and in 1,130 he believed that he found parasitic bodies. Sjöbring laid much stress on cell inclusions. Russell described his fuchsin bodies, which were spherical or oval. L. Pfeiffer of Weimar published several monographs on the protozoa as a cause of cancer. Eisen brought out his *Cancri amœbæ*. Korotneff believed that he had found an organism which he termed *Rhopalocephalus carcinomatosus*. Bosr found and described an organism that he called *Myxosporidia coccidia*. Gaylord of Buffalo described at great length bodies that he believed bore an etiologic relation to cancer. Sanfelice of the University of Cagliara emphasized the etiologic importance of bodies that he named *Saccharomyces neoformans*. A very large number of other publications on this subject made their appearance, none of which differed in any essential point from those bodies just mentioned.

While the presence of the aforesaid bodies described by the different observers can be demonstrated and are present in a large proportion of the cases of cancer, all the requirements necessary to prove them to be the organisms solely responsible for cancer have not been fulfilled. The requirements necessary are (1) the organism must be isolated; (2) a cancer must be produced when the organism is introduced into another body; (3) the organism must be recovered from the cancer produced. It has been shown that, while the first requirement has only apparently been fulfilled, the second has been, in a number of cases, seemingly produced. More careful investigations have proven that the experimental growths were not cancer. The third requirement has not been fulfilled.

All of the work mentioned above was carefully reviewed in all its details by the cancer committee, who, in their second annual report to the surgical department of the Harvard Medical School, showed conclusively that the bodies described by the various investigators under different names were not cancer nor the cause of cancer. I can do no better than to quote in full the results of their labors. They bear the marks of painstaking and conscientious work. The conclusions of the Harvard cancer committee were written by Edward H. Nichols and are as follows:

It has been claimed by the adherents of the theory of the parasitic origin of cancer that

1. A proliferation of epithelial cells analogous to the lesions seen in cancerous tumors can be produced by certain well-known protozoa (nodules caused by the Coccidium oviforme).
2. Certain skin lesions characterized by epithelial cell proliferation are due to the action of a so-called protozoon (Molluscum contagiosum).
3. Blastomycetes are constantly present in human cancers and are the cause of the lesion.
4. By experimental inoculation of animals with blastomycetes, true epithelial or cancerous nodules can be produced.
5. Finally, the well-known endocellular bodies seen in the protoplasm of cancer cells have a definite morphology, are parasites and the cause of cancer.

It has been the object of the investigators, the results of whose work appear in the preceding pages, to study each of these questions. As a result of the lines of work pursued by them under the direction of the Cancer Commission during the past year, it is concluded that:

1. The lesion produced by the Coccidium oviforme is essentially a process of chronic inflammation and is not analogous to the lesion seen in cancer.
2. The lesion of Molluscum contagiosum is characterized by certain changes in the epidermis, is not due to the action of a protozoon and is not analogous to cancer.
3. The so-called "blastomycetes" (saccharomycetes) of Sanfelice and Plimmer are torulæ.
4. The lesions produced by these "blastomycetes" (torulæ) are, essentially, nodules of peculiar granulation tissue, are not cancerous, nor, in any sense, true tumors.
5. Blastomycetes are not constantly present in human cancers.
6. The peculiar bodies seen in the protoplasm of a cancer cell are not parasites, nor the cause of the lesion, but probably are, in part at least, atypical stages of the process of secretion by glandular epithelium.

It is clear that in the present status of the etiology of cancer, bacteriologically considered, the case has not been proven. But it does not follow that it will not be shown that cancer is due to a specific and well-defined organism. It may be an organism so minute as not to have been brought within the range of the microscope. It is possible that no stains have yet been found that possess the requisite affinity for its complex molecular constitution. The necessary artificial medium for its cultivation remains for some future investigator to solve. Be it what it may, since the clinical features give strong evidence of the infectiousness of cancer, the search must and will be continued along the same lines.

In this search for a specific contagium, cellular metabolism must not be forgotten. Its consideration and study is perhaps more important than the isolation of a specific germ. It can not be denied that the more exact our knowledge of cytomorphosis becomes the clearer will be our understanding of cell proliferation. It has long been understood that there must be certain stimuli that cause cell growth and certain inhibitors that limit cell development and exercise control in accordance with the requirements of the tissues. Certain other influences bring about a disturbance of the normal equilibrium between the stimuli and the inhibitors. It is evident that the exact nature of the stimuli, the inhibitors, and the disturbers must be ascertained. This involves a study of the cell constituents and the fluids that surround it. As we see, it is a question of chemistry.

In this connection, it is important to take note of a very novel hypothesis bearing on the formation of new growths propounded by Homer Wakefield.

He believes that a neoplastic formation is not an exaggeration of anabolism, increased or excessive proliferation, but that it is a product of katabolic stasis; that is, normal cell division is unimpaired, the anabolic process continuing to the point of maturity of the cell. It attains the meridian in its life and reaches the post-meridian state when it should undergo normal katabolism, a complete dissolution and disappearance of the cell. Instead, something has supervened to check katabolic changes, the cell becomes superannuated and its existence is prolonged until finally it undergoes various degenerative changes. Normal cell production continues, but normal cell dissolution is retarded or abolished, hence the cells accumulate, producing the appearance of what is regarded as cell proliferation.

This condition Wakefield has termed katabolic stasis or subkatabolism. He states that the intercellular substance is richly alkaline and that the tissue cells are more or less soluble in it. The cells, during the period of their growth, generate sarcolactic acid and during this period they are richest in protoplasm. After the meridian the cells offer decreased resistance to the solvent powers of the alkaline medium and lose their protoplasm, the nucleus alone remaining.

He infers that, before the meridian is reached, the acidity produced by normal cellular activity protects the cells by its neutralizing effects on the intercellular alkalies and that this preserves the investment of protoplasm. Now, if from any cause, the normal alkalescence of the intercellular substance is reduced or if, in a given area, the acidity increases, katabolic stasis affects all the cells in that area. Suboxidation consequently takes place. It is therefore believed that cancer formation is an acid process.

Briefly, tumor formation, according to this hypothesis, rests on a stasis of katabolism, subkatabolism and suboxidation, in the presence of normal anabolism. The cell inclusions, observed by many investigators and regarded by them as protozoa, cancer parasites and as blastomycetes, Wakefield regards as products of disturbed nuclear division. This new hypothesis, at present, rests only on theoretical grounds, but the arguments are so thoughtful and so suggestive that they deserve careful attention. Their chief importance, at this time, consists in the bearing out and support of the methods of research along chemical lines.

We are all familiar with Virchow and the birth of cellular pathology, with Ehrenburg and the growth of bacteriology, and now we have arrived at, and are in, the humoral or chemical era. The trend of all research at the present time is beyond cells and beyond bacteria. It is to determine the chemical operations in and around the cells. This line of research began in the leucocytes because they were the most available. In their study it was possible to establish basic principles. From the leucocytes to the erythrocytes was only a step and then the epithelial and connective tissue cells received attention. This field of research is a new one. It is occupied by a vast army of patient and earnest toilers. The fruits of their labors will be beyond our greatest expectations. It is our present purpose to see if the cancer problem can be solved along these lines.

What has malignant disease to do with immunity? The entire subject of immunity has to do with infection. It has to do with its nature, mode of action and control. Has cancer any characteristics that pertain to infection? Bacteriologically we have found none. Clinically we have a mass of evidence that would seem to place cancer among the infectious diseases.

In order to have a clear understanding of the modern conception of immunity it is necessary to review as briefly as possible and in barest outlines without comment the most important features of our present knowledge of the subject. Much material that may seem essential to a complete elucidation of this great and important subject, had to be eliminated on account of the limited scope of this dissertation.

More than a century ago we find that John Hunter was familiar with some antiseptic properties of the blood. He found that a small amount of putrefying material could be added to a given quantity of fresh blood without producing putrefaction. Consequently, he advanced his doctrine of "the living principle of the blood." This, as an observation, was almost forgotten and its import was not fully realized until Nuttall, in 1888, began his systematic work in Flugge's laboratory, studying the antibacterial properties of the body fluids, especially the blood serum.

The greatest impetus to the study of immunity was given by Metschnikoff in calling attention to the participation of the leucocytes and other cells in the process of infection, establishing his well-known theory of phagocytosis. His views are so well understood that we need only to call attention to them at this time.

Following Nuttall, Pfeiffer discovered, in 1894, "the extracellular disintegration and solution of cholera spirilla in the peritoneal cavity of immunized guineapigs."

The greatest attention and interest was aroused by Behring's great discovery of antitoxic immunity. Bacteriologists at once endeavored to elucidate by elaborate researches the exact way in which immunity was established. Chief among these was Ehrlich. It was soon shown, however, that immunity in most bacterial infections did not depend, in the main, on the antitoxic principle.

Pfeiffer's phenomenon afforded a starting point from which Metschnikoff, Bordet, Ehrlich and Morgenroth began their labors and brought forth a series of discoveries that have been epoch making.

A series of antibodies were differentiated and classified as antitoxins, antienzymes, cytotoxins, agglutinins, precipitins and coagulins. Antibodies were in turn produced by these, with the exception of the antitoxins.

It was determined that to every cellular group of an animal species there appears to correspond a specific cytotoxin. These various toxins have been termed leucotoxin, neurotoxin, spermotoxin, nephrotoxin, thyrotoxin, etc.

These antibodies have been divided into two groups, first, the antitoxins which are single bodies; second, the cytolysins, whose antagonistic effects require the cooperation of two bodies.

Of these two bodies, the one which actually destroys the foreign cells is normally present in the cells or fluid of the organism, but it seems incapable of action without the intermediation of a body which is distinguished from it by a greater resistance to heat. The two elements composing cytolysins exist quite independently of each other so that one may be present without the other or be artificially removed without affecting the other.

To demonstrate the mode of action and constitution of the specific antibodies, Ehrlich has propounded the theory of receptors or side-chains. The atomic grouping of the toxin molecule, which affects the union with antitoxin as well as with a particular cell, he has designated as haptophore groups.

In view of the fact that certain molecule groups of the living protoplasm favor the taking up of certain poisons, he has termed them receptors. According to his theory of antitoxic formation, after the introduction of toxins the receptors are produced in excess and finally are thrown off into the blood as useless ballast. The free circulating receptors are the antitoxins, termed amboceptors, intermediary bodies. The action of antitoxins is explained thus. They take charge of the haptophore groups of the toxin molecules and prevent them from approaching the receptors of the tissues.[2] There are as many receptors as there are toxins, while almost every day new ones are discovered.

Behring gives the most exact and brief definition of Ehrlich's antitoxin theory: "The same substance, which, when incorporated in the cells of the living body, is the pre-requisite and condition for an intoxication, becomes the means of cure when it exists in the circulating blood." Every antiserum protects only against substances through which it becomes immunized. Every antiamboceptor protects only against its particular amboceptor.

Ehrlich and Morgenroth found, in experiments with goat's blood, thirteen different new lysins which represent so many receptors. "The receptors are in the cells, not for the purpose of linking poisons to the cells, but to seize certain foodstuffs, particularly proteids, and the toxins, bacterial and other foreign cellular substances, if capable of inducing the immunizing reaction, chance to have the requisite combining affinities for the receptors."

The living body possesses bactericidal and cytolytic substances which may protect it by destruction of invaders or may injure it by destruction of its own cells, according to the mates with which they are paired.

In considering the physiologic mechanism of the cells we find that they are designed, primarily, for the assimilation of food, and secondarily, to meet pathologic conditions, the production of antitoxins, cytolysins and other similar bodies. The receptors are in the cells for the purpose of taking up foodstuffs, chiefly proteids. The toxins and bacterial cellular substances have combining affinities for the food receptors, if they are capable of inducing an immunizing reaction.

In producing immunization against bacteria, it is the intermediary body (amboceptor) which is generated. It has been found that these antibodies have a specific relation to the substances which caused their formation, as has been shown by the injection of a specific serum into an animal at certain intervals, of toxins, against which an antitoxin is desired.

The specific nature of these antibodies is further shown in their application to serum diagnosis, as shown by the Widal agglutination test for typhoid fever and the serum test in the diagnosis of bacillus dysenteriæ Shiga, an organism shown to be the cause of acute dysenteries by Flexner, Vedder and Duval.

When Roux and Yersin discovered diphtheria antitoxin and Ehrlich the origin and mode of action of antitoxin, a lasting foundation for the study of immunity was laid. It was positively shown that "soluble toxins enter, as assimilable substances, into combination with constituents of the body cells for which they have an affinity," and are enabled to produce immunity or to exert toxic effects.

The expectations that we should soon be enabled to solve all questions regarding the action of toxins after the discovery of soluble bacterial toxins, have only partly been realized, especially regarding the action of the pyogenic micrococci, which concerns us most as surgeons.

However fruitless, hitherto, the practical results regarding toxins of many pathogenic and especially pyogenic organisms, the principle has been established, and it is only a question of method and time when all body toxins and their antitoxins shall be definitely known.

Pfeiffer directed his attention to the bacteria and found substances, toxins, in cholera spirilla, which became free only after the bacteria were dead and which were termed intracellular poisons. This was a most important step in advance, but we must acknowledge that we know as yet very little about the action and nature of intracellular bacterial poisons.

It is interesting to note from the result of Flexner's experiments with venom that their action on red blood corpuscles, leucocytes and nerve cells is like that of duplex cytotoxins, which depend on the combination of intermediary bodies contained in the venom on one hand, with corresponding complements in the cells or fluids acted on. This is shown by the addition of venoms to fresh blood, which brings about the quick destruction of the red blood corpuscles. If the fresh blood has been washed with an isotonic salt solution, so as to remove all the complement, we find that the corpuscles are not dissolved, but agglutinated. It seems that the venom serves chiefly to bring "into necessary relations with constituents of the body cells, poisons we already harbor or may generate, but which are harmless without the intervention of intermediary bodies."

Flexner and Noguchi have shown that the leucotoxic, the neurotoxic and other cytotoxic properties of venom depend on combinations of venom, intermediary bodies with complements contained in the cells poisoned by venom, or in the fluids bathing these cells, indicating that the snake venom contains only a part of the complete poison.

Flexner and Noguchi also demonstrated that hemorrhages in various tissues of the body resulting from poisoning from certain venoms is due to the presence in venom of a cytotoxin which has the power to dissolve endothelial cells, which they termed endotheliolysin (hemorrhagin). It causes extravasation of blood through its direct solvent action on capillary endothelium.

The hemolysins have been most extensively studied because of their great pathologic significance, and it has been found that many bacteria have hemolytic power. The secondary anemias, so constant in streptococcus infections, in pneumonia, typhoid fever and other diseases, afford a most striking example.

Normal blood serum contains antihemolysins which protect red blood cells from bacterial hemolytic agents. Associated with hemolysins are bacterial hemagglutinins, possessing the power to clump red corpuscles.[3]

Heuter and Klebs believed that thrombi were due to the coalescing of red blood corpuscles. Welch calls attention to hyaline thrombi formed by agglutinated red corpuscles. White corpuscles are agglutinated by certain bacteria and also by pus cells.

What is urgently needed is a separation of these poisons and a determination of their source, constitution, mode of action and degree of specificity.

It will not be out of place here to allude to the studies made of the ductless glands, because of their supposed bearing on immunity. Sajous urges that the adrenal extractives have a decided affinity for oxygen, offering a key to tissue respiration and to the functions of all other organs now classed as the ductless glands. It has been found that the red corpuscles are not the only carriers of oxygen, but that the blood plasma contains and distributes this gas. Schmiedeburg, Jacquet, Claud Bernard and others demonstrated the existence of an oxidation ferment in the plasma, and these bodies are now entertained as an oxygen-laden secretion. This secretion is believed to permeate nearly all the body elements. The blood also contains a fibrinogen body which combines in certain quantities with fixed portions of the plasma's oxygen. The changes in the temperature of the blood were traced to variations in the amount of the fibrinogen in the plasma. The adrenals have been shown to be connected with the anterior pituitary body by various sympathetic ganglia. The anterior pituitary body is regarded as the governing center of the adrenal system. Over-activity of this body increases the adrenal secretion, consequently oxidation, therefore vital resistance. Depression of the activity of the pituitary body causes decreased supply of oxygen, consequently depressed vital processes.

---

[2] Ehrlich: Schlussfolgerungen, p. 176.

[3] Heuter-Klebs, p. 731.

The thyroid secretion, thyreoidin, has been shown to sustain the efficiency of the pituitary body. Excessive thyreoidin production stimulates the pituitary body and produces exophthalmic goiter. Deficient thyreoidin production leads to myxedema. The adrenals, the pituitary body and the thyroid gland constitute the adrenal system. According to this line of research, it is believed that toxins act directly on the adrenal system, and, by decreasing or increasing its secretion, decrease or increase the oxidation process. Certain toxalbumins and many drugs stimulate the adrenal secretory powers to a certain limit, and, when exhibited in excessive doses, depress or arrest the functions of this system.

The posterior pituitary body has been shown by Berkley, Andriezen and others to be the chief functional center of the nervous system. It is the center for such emotions as shock, excitement, etc. It governs all organic functions through the nervous system. The secretions of the pancreas and spleen, according to Schiff, and later by Herzen, unite and change trypsinogen into trypsin, a solvent for the albuminous bodies in the pancreatic juice. This ferment performs an important part in immunizing processes, in that it destroys toxalbumins.

Viewing these labors in the light of Ehrlich's researches, the oxidizing substance represents the amboceptor; the spleno-pancreatic internal secretion, trypsin, represents his complement. To produce a proteolytic action of trypsin, fibrinogen and the oxidizing substances are required. These views are somewhat at variance with those commonly accepted, but are of sufficient importance to deserve consideration in this connection.

From the foregoing it would seem that the doctrine of phagocytosis plays an unimportant rôle. But we find that the French, or phagocytic school, at the head of which is Metschnikoff, recognizes the full significance of acquired immunity and the cytolytic principles represented by the co-operative action of intermediary bodies and complements. The German, or humoral school, led by Ehrlich, recognizes the leucocytes to the fullest extent.

The chief difference between the French and the German schools consists in the belief by the advocates of phagocytosis that the complements reside in the leucocytes, whereas the adherents of the humoral school believe that they exist in the blood plasma.

While, in what has here preceded, we have been concerned in the consideration of chemical problems, we must not overlook the fact that behind all is a governing force which resides in the central nervous system.

The practical outcome of these studies has been found in the production of antitoxic sera, some of which have been proven to have a definite and exact effect under certain conditions. We find these sera divided into two principal groups, (1) those that have an anti-bacterial action, and (2) those that have a purely antitoxic action. Of all the sera the diphtheritic is best known. According to Welch the mortality of diphtheria has been reduced from 40 per cent. to 15 per cent. by its use.

Antitetanus serum has been disappointing. Reports coming to us from different sources are conflicting, the mortality ranging from 0 per cent. to 70 per cent. from practically the same methods, which consist in administering the serum by the subcutaneous, intracerebral and the spinal methods. Antityphoid serum has failed to fulfill expectations even more than antitetanus serum. The antistreptococcus serum of Marmorek, while it seems to have exerted a specific effect in purely streptococcic infections, appears to exert no influence in the presence of mixed infections. The antipneumococcic serum has not yet emerged from the experimental stage. Nothing can be said of its effects. The antiplague sera of Haffkine and Yersin demonstrated that, as a preventive, it reduced the number of cases to one-twentieth and the mortality in a given number of cases was reduced from 33 per cent. to 13 per cent. (Calmette). The antitubercle serum has been shown to have a specific effect on tuberculous tissue, but remains powerless in the presence of mixed infections. The antivenom serum has been demonstrated to have a positive usefulness in certain snake bites. Calmette's antivenin has been proven to be of undoubted use in leprosy.[4]

Many other sera have been described, but their usefulness thus far has been shown to be of an uncertain nature. Consequently, we will leave them out of consideration at this time.

When we pass in review all that is positively known in relation to the question of immunity, we can not deny that some of the principles underlying this great question have, in a measure at least, been revealed. The evidence is conclusive that "the same substance which, when incorporated in the cells of the living body, is the pre-requisite and condition for an intoxication, becomes the means of cure when it exists in the circulating fluid."[5]

Ehrlich, in his investigations of diphtheria toxins, demonstrated "that soluble toxins enter as assimilable substances into direct combination with constituents of the body cells for which they have an affinity, and only thereby are enabled to bring about immunity or to exert toxic effects." Further, in connection with Metschnikoff, Bordet, Morgenroth and Ehrlich, it is shown that "the organism possesses a power to produce substances specifically antagonistic to all sorts of foreign cells, cellular products and derivatives. The substances capable of inducing this immunizing reaction appears to be mainly of an assimilable, albuminous nature, or at least intimately associated with such material."

---

[5] Behring's Definition of Ehrlich's Theory Concerning Antitoxin. Welch.

The principle of toxins and antitoxins has become as firmly established as any other in medicine or surgery. We have noted that antitoxins from pure cultures have a certain affinity for and possess immunizing power in specific infections, but fail in the presence of mixed infections. We see at once that failure to immunize does not violate the principle, but that the method of application has been at fault. We know that diphtheria toxin has a specific effect for the products of the Klebs-Loeffler bacillus, and that it controls and cures in the presence of these, but fails when there is an admixture of other forms of infection. This is shown by the 15 per cent. mortality which still exists. We have noted that antistreptococcus, tubercular and plague sera have a specific and a decided effect in pure infections, but that they fail in the presence of other specific germs. We observe with satisfaction the certainty of the action of a given antitoxin in its union with the toxin from which it was produced. It at once becomes apparent that, in the presence of several toxins or a mixed infection, it will require several antitoxic substances, a combination of antitoxic sera, or a serum containing different kinds of amboceptors, so combined as to meet and unite with the several toxins in a given case. Coley endeavored to meet such indications by combining streptococcus and bacillus prodigiosus sera in treating inoperable sarcoma.

These observations presage a revolution in therapeutics, which perforce means a refinement in diagnosis, beside which, what we do now will scarcely bear comparison.

The inferences to be drawn from the foregoing indicate that the future work will be biochemic. It appears that the solution of cell metamorphosis, as it is observed in pathologic conditions, will be in the field of chemistry. Ehrlich's theory of the side-chains has given us a working hypothesis almost as practical as the atomic theory when applied to chemistry. It is not an idle dream to believe that the revelations of the future will not only consist in a complete exposition of cells and body fluids, or a perfect understanding of the governing brain centers, but may extend to the life principle itself, although life itself may and will ever belong to the unknowable.

Our chief interest, however, will always center in the cell and its governing influence. Just what influences are responsible for normal cell division may never be known. But it is within the bounds of human possibility to know what influences may be responsible for atypical and excessive cell growth. Excessive cell growth, both in the leucocytes and connective tissue cells in acute infections, we can assume to be due to toxins that are in excess of the amboceptors. The existence of cytolysins and anticytolysins is now undisputed. The one destroys, the other protects the cells. We have noted that the chief function of a receptor molecule is to combine with nutrient molecules, a metabolic, a chemical process. The birth and growth of the cell is restricted within certain limitations and is regulated by chemical law. Now the problem depends on our ability to ascertain the exact influence that carries cell division beyond its normal bounds and causes excessive cell growth as we observe it in malignant new growths. That the process is one of localized excessive nutrition is apparent. The localities of predilection are frequently at points where the cellular elements are exposed to frequent insults, where the tissues are damaged, establishing a *locus minoris resistentiæ*, as, for example, in the mouth, gastrointestinal tract and the female reproductive organs. A point of least resistence, damaged tissue, if you please, always offers a soil for bacterial invasion. Cancer very often develops in tissues that have long been irritated, no doubt liberating a complement that unites with a specific infection when introduced under proper conditions. Such is not always the case, however. In fact, we know that in the majority of tissues that sustain irritations and almost constant traumatism for many years never become malignant. The simple traumatism does not develop cancer. A specific toxin must be introduced, probably also an intermediary body to complete the side-chain, which increases karyokinetic energy. We have noted in our studies of immunity that the life or death of the cell depends on its intra- and extra-cellular composition, so we may say that the whole process, whether it relates to normal or excessive cell growth, is chemical.

An objection may be urged at this point, which consists of the fact that the propositions of immunization thus far considered affect groups of cells extending over a wide range, i. e., the vascular, the muscular and the glandular or cerebrospinal systems. It has been shown that cancer is always at the outset, and often throughout its entire course, absolutely a local disease. It would not seem rational to attempt immunization of the entire system against a strictly local disturbance. We will naturally turn our hope toward a method that will enable us to affect local immunization.

That local immunization is possible has been demonstrated by P. Römer in the following convincing abrin-immunization experiment. As is well known, abrin, which is the toxalbumin of the jequirity bean, will produce a severe conjunctivitis in animals and men. Ehrlich had demonstrated that rabbit's conjunctivæ became immune after the instillation of abrin. Römer instilled into the right eye of the rabbit weak abrin solutions, the dosage being rapidly increased until immunization was produced. In three weeks the rabbit was killed. It was then shown that if the right conjunctiva, which had undergone severe inflammation, were rubbed and macerated with a certain amount of abrin and injected into a healthy animal, it had no effect. But, if the conjunctiva of the left eye, which had received no instillation, were rubbed and macerated with abrin and injected into an animal, death always followed. Römer concluded from this observation that in conjunctival immunizations a part of the autotoxin existed in the conjunctiva itself. A local antitoxin was produced.

It would seem that these results establish definitely the principle of local immunization in indifferent tissues. These observations have an important bearing on the adaptation of the cells in local affections. That local affections of various forms or general affections with local manifestations can be best managed by the local introduction of exceedingly small doses of the specific remedy, was shown by Professor Bouchard before a recent meeting of the Egyptian Congress. He found that articular rheumatism disappeared after the injection *in situ* of small doses of salicylic acid, in some cases only half a grain. We must conclude that local cell metabolism can be influenced by local rather than by general diffusion. The inhibition of excessive cell growth must be accomplished in the same way.

It would seem, then, that the cancer question must be solved along the lines of chemistry. Since we know that contagious or infectious energy does not depend on the bacterium itself, but on its products, which are purely chemical, it would seem that it matters little whether the specific parasite is found or not. Since the cancer germ has thus far successfully eluded the most vigilant search it becomes more and more evident that in the field of chemistry will be found the solution for our problem.

It will be difficult to rid ourselves of time-honored views. Purely theoretical speculation, like the hypothesis of cell proliferation from inclusions of embryonal matrices according to Cohnheim, must give way to the demands of modern science that insist on actual observations and practical demonstrations.

Now then, will it be unreasonable to hope, that when protoplasmic changes are thoroughly understood and when the body sera have given up their secrets and the influences that govern cell growth, that we may also find the antibodies which will inhibit cell multiplication beyond natural bounds?

The studies in the field of immunity have, as yet, only assumed the proportions of the initiatory stage. A vast unexplored wilderness lies before us. The pioneers have begun their work well. They have outfitted themselves in a manner that will, in the near future, enable them to throw unexpected light in the pathway of their conquest of discovery. They are only on the verge of this vast domain. What lies beyond the borders we can no more foretell than could Boyer know that in twenty-our years after his death we should have anesthesia and that in fifty years the world would have antiseptic surgery. And yet, in the light of our present knowledge the hope, amounting to a conviction, arises in us that even in our lifetime, if we are spared a few years more, we will have an exact bio-dynamic and bio-chemic science that will make diagnosis accurate and precise d one that will enable us to treat and control all in- tions with an exactness not now possible. While the rgeon is now constantly encroaching on the field of the internist, the time is not far distant when the physician may not only reclaim his own, but with it that large group of neoplasms known as malignant growths that from time immemorial has been the exclusive property of the surgeon.

SOCIAL CONDITIONS IN AMERICA IN THEIR RELATION TO MEDICAL PROGRESS AND DISEASE.

ORATION IN MEDICINE, DELIVERED AT THE FIFTY-FOURTH ANNUAL MEETING OF THE AMERICAN MEDICAL ASSOCIATION, HELD AT NEW ORLEANS, MAY 5 TO 8, 1903.

J. M. ANDERS, M.D., LL.D.
PHILADELPHIA.

Another spacious year with its varied channels of energy and activity in medicine has closed. While a faithful chronicle of the facts, data and achievements showing the progress of internal medicine for that brief period would have proved an appropriate topic, I have availed myself of the choice privilege granted by this Association of selecting my theme, and purpose to consider the subject of the relation of American social conditions to the progress of medicine and disease and the import of modern economic and professional tendencies in forecasting the immediate future.

The state of American society, founded on democratic ideals, is one in which the true function of the physician has ever been both intellectually and morally beneficent. It has ever been the fate of the medical profession, however, to have its past outgrown and stifled by the enthralling energy and life of its present and to forget to fix its gaze on what is grand and significant in inherited associations and opportunities. Conversely, the fundamental principle of human development, to-wit, that the present is quickly passing under the control of the future, which transcends an enlightened self-interest in the present, is yet to be fully realized and appreciated. In the life of our civilization the physician has constantly found himself in the presence of golden opportunities to render a service to the community, to add his private thought to the public opinion. His high calling and the stage of social development from which he has proceeded have ever invited to the development of an expanding and humane spirit. He has been, however, in many cases too closely chained to his special work. Per contra, the individual member of commanding worth and formidable individuality, like the Spartan and the Greek, has fortunately lent his own spirit to the genius of the great organism—the medical profession—and its higher destiny. That genius is no sluggard, and the motive of action is not the pursuit of gain or of personal aggrandizement, but an incessant advancement of our art and science and an application of the faculties to the higher interests of civilization. What is needed in medicine from the standpoint of sociology at the present day in America is the true "scientific spirit clothed with human interest," to give force and direction to the means available, not only with a view to the application of science to the healing art, but also to enable our profession to find its true place in the body politic and its intrinsic importance as a factor in modern civilization.

While there are certain things and events common to all in our psychic and social development, enlightened society will grant that the larger events in American history, assuming that "the first duty of society is the preservation of life and the comfort of its units," have not been so much dominated by legislative authority and social customs as by the march of science, more particularly medical and hygienic. In a country as vast as ours, however, there could be no uniform law covering the details of results in matters medical. These have been in the past and will in the future vary somewhat with the climate, physical conditions, degree of culture and opportunities presented by the widely separated regions. As a consequence, in displaying proportions and the practical results of scattered sections, the final adjustment of their claims only becomes perceptible and appreciable in their broader and higher generalization. The whole range of American historic data and events indicates an imperishable foundation of scientific achievement, and furthermore establishes firmly a relationship between medicine and the scientific principles underlying social conditions and phenomena that is both positive and vital. As touching the American medical history of the long past, we can see the major advances and their influence on social laws and the progress of civilization only by grouping data and established facts and applying the process of generalization to these composite phenomena. In this connection it is to be regretted that our possession of unclassified facts is increasing with uncomfortable rapidity. A comparative and historic study of the medical literature of America, taking any of the older countries as a standard of comparison, in respect to this method of generalization, can scarcely prove even measurably satisfactory. Much of the history of native medicine is crude and it were impossible to give it either crystallized or concrete form. Epoch-making discoveries and important, far-reaching scientific effort is justly the boast of the American profession. Systematic effort at a rigid classification of facts by the modern statistical method, however, has not been made, and only a partial scientific use of the ever-advancing events for the different historical periods has been attempted.

The concrete, comparative and historic method of study which alone furnishes a proper basis for generalization and serves to point out the relations of medicine to other human activities, would insure a wholly fresh treatment of the earlier medical annals of America. The physician in his economic or professional dealings has not followed his self-interest in comparison with his measure of enlightenment to an equal extent with men in other lines of human activity, but the fruits of his unselfish labors are, when taken collectively, presented in the form of a heterogeneous mass of details. It should be recollected that it is only the larger events, the accurately grouped facts after the method of generalization to which I have referred, that go to make up the bulk of medical history and medical law. The practical results of the method of simple generalization would show clearly the final utility of medical and sanitary knowledge in the social universe and manifest its relation to everyday life. Obviously in a young republic like ours something must be allowed to propinquity—to nearness to a confusing and disordered mass of facts and phenomena.

It has been well said: "A landscape is beautiful because distance has reduced its chaos of details into order."

Those endeavoring to make a personal study of the medical and sanitary requirements of our insular possessions, more especially under new and changed conditions, can not hope to gain more than a fragmentary knowledge. Much important and accurate information touching the social, climatic and medical conditions and necessities, however, is available through the Division of Insular Affairs, in the War Department at Washington. It is clearly incumbent on the organized profession of the United States to undertake studies on a larger scale than that of individual effort. Moreover, the interrelations between tropical medicine and the sciences before alluded to, i. e., social and sanitary, is a question for the immediate future; thus step by step may we hope to erect a stairway that will lead to a new temple of knowledge.

The foundation for social order, education and a fair measure of self-government under military rule having been laid both in Porto Rico and the Philippines, there is presented to the profession of the United States an opportunity amounting to an obligation to carry into those new possessions the light of modern sanitary and medical science. The peoples of those islands are as clearly entitled to the benefits offered by our science and art as they are to those pertaining to their fundamental civil and personal rights, as guaranteed by the Constitution of the United States.

From the America that Cortez invaded until the present the most treasured resource of our nation to the physician has, in a peculiar sense, been human life, and in respect to this economic principle we are, at present writing, merely following in spirit our thoughtful forebears. The medical profession never has valued life in terms employed in denomination nor by its productive power, but rather measured it from a divine and humanitarian standpoint. Certain it is that with advancing civilization there has come a higher and higher appreciation of the value of agencies intended to promote longevity and minimize disease and suffering. And this tendency to preserve human existence, apart from sentimental considerations, is born of a principle long adhered to by the medical profession and continuously unfolding itself in the individual and in organized medical bodies. It is clear, without seeming extravagance of statement, that greater justice is done by the medical profession of America to the condition of society just pointed out than in foreign lands, since it is more thoughtful for the youth and hope of our profession. It is to the flower of that youth, with its new and hidden virtues, that we must look for disclosures in the province assigned to the higher and more complex professional bodies of the future. Modern democratic institutions, including medical schools, are in the ascending scale of civilization, infusing into our profession men who are armed with potent resources from the pedagogic world.

The present-day educational facilities and developments show an ever-increasing beneficent tendency, and the standard of qualification has passed, or is passing, beyond the stage in which there is a mere desire to acquire an elemental knowledge of disease and its treatment in this country; a new character and a new vital and moral force is happily presuming to show itself in public action for the benefit of mankind. This genius stands ready to kindle its fires and materially aid in offering the means of human welfare and the revelation of new truths.

An appreciation of this fact by professional bodies is necessary in respect of the future; for medical societies organized to obtain the highest potency must compete successfully with other societies, or they will vanish from view in the stress of social and scientific evolution.

But though the obscure rival of the Goddess of Minerva, who had broken the loom of Arachne in her jealousy, executed wonderful tasks by her unaided strength, in the process of progress towards higher efficiency the individual ceases to be a factor of first importance. The process of development, whether considered in its economic, political or purely professional relations, demands the subordination of the interests of the individual to the larger interest of the organic whole. The dominant and controlling feature underlying an infinite variety and complexity of details of that upward movement of professional and social evolution is compatible with a remarkable simplicity of governing principle. Our plain duty is accordingly to endeavor to understand the nature of that governing principle which is distinctive and characteristic in that it does not regard the interest of existing members as supreme, but is seeking to establish conditions which are favorable to the interests of a larger future.

As regards the question of the relation of medical work and progress to our social system, the time is probably ripe for a revision of certain elemental and fundamental principles and customs, although it is obvious that neither social agencies nor the general public manifest a proper comprehension of its necessity. While science is telling us about the pathologic intricacies of disease processes, their bacteriologic causation and cure with unparalleled rapidity, important social and economic questions that affect especially the comfort and health of our teeming town-bred populations are subordinated. Again, in a land of popular civil government the medical profession should be organized in a manner that would render it equal to enlarged duties which naturally should devolve on it. I refer to such matters as the control and regulation of asylums for the insane, municipal health boards and the municipal hospitals for the sick poor, for contagious diseases and the like.

Certain tendencies of modern American life, considered with reference to the welfare both of the medical profession and general public, offer a most promising field for investigation and progress. The temptations of the practical, over-strenuous life of the present and past generations have left their impress on our profession. Something, however, must be ascribed to our nervous climate, reinforced by certain elements of the American spirit-aggressiveness and an unconcealed idealism. Neither should the powerof the initiative of the American, his shrewdness and his energy be overlooked. It may be doubted, however, whether there have been accomplished achievements and results commensurate with the impetuosity that characterizes all paths of professional activity. The universal spirit of haste has taken possession of our professional life; it permeates the air of the age, and the principal cause of this state of affairs is to be found in our ardent, every-day ways of living, and its cure must result from a readjustment of the home life and habits of the professional and other classes. It means a return from our present-day restlessness and rush to a quieter period, to a "Mansfield Park," with its charm of quiet village life; a return to a normal life, with natural intellectual tastes, and to calm, patient, original observation that fosters vital force and successful endeavor.

If authors and investigators were to bring forward only definitive and well-weighed pronouncements on all points at issue, it would carry us from the surface to the heart of things, and our labors would be more strongly marked by originality and power.

The spirit of undue haste which characterizes our national life is nowhere better exemplified than in American medical literature, despite its many virtues, its broad, liberal spirit and freshness. Never, in American history, whether deliberately or unconsciously, has so much current literature been placed at the disposal of physicians. Too generally medical thought and opinion, which is not of necessity medical truth, finds literary expression. The obvious weakness of it all is an enforced tendency to waste one's time in reading matter which is unapproved by common opinion. Extending this thought, it may be questioned whether to carry views and ideas beyond the domain of existing knowledge does not hinder rather than facilitate progress.

There is a list of honor among American writers, and it embraces authors whose literary product shows not only a sharp scrutiny of facts, but also the highest and most characteristic utterances in medicine. Indeed, the worth and power of American medical literature, either in its content or method, scarcely receives an unprejudiced estimate abroad.

In the field of letters we point with inordinate pride to the late Dr. Oliver Wendell Holmes, and our contemporary, Dr. S. Weir Mitchell. Fiction by medical authors lives and will live in America.

It may be questioned whether American nationalism, as evidenced by the creation of a native literature, should be the principal aim, although the consistent use of American material is to be advised and encouraged. We need to retain the conservative European spirit and keep wide ajar the door that leads to the treasures of continental literary traditions. Foreign peoples are and have been immigrating by the hundreds of thousands yearly; they have penetrated into the remotest points of this country, carrying effective training with them in many instances. Hence, admitting that the prescience of genius is the possession of many, there are fewer distinctly American medical authors than at first blush would appear.

> "The Celt is in his heart and hand,
>   The Gaul is in his brain and nerve;
> Where, cosmopolitanly planned,
>   He guards the Redskin's dry reserve."

Acknowledgment is due the great value and significance of the unparaleled heritage handed down by the older nations, particularly England, Germany and France. The path of fame for a nation no less than for an individual lies in the direction of constructive effort and sensitive receptiveness of the impressions and tendencies of the age irrespective of territorial limitations, and of a keen sympathy and close touch with the movements of the times in all lands.

Our literature is not an indigenous growth, yet stern of purpose; it is not, and, let us hope, never will be, sluggish in turning to foreign sources. It has, however, developed certain characteristic features, a distinct national flavor and a perfume "as plainly native as the arbutus."

American industry, with its attendant wealth and power, and the enlarged opportunities it offers to all classes of society for successful business enterprise, has quite generally proven attractive to and often filled with fervent hope the American physician, and with increasing means he has found his social position to improve.

In America the achievement of considerable financial success, however, is possible without taking high ground in a professional or ideal sense. The medical profession is integral in the effects of our economic evolution; it obtains stray glimpses of the avenue of glittering gold; but its central effort, if it desires to remain true to human perspective, contemplates a systematic development of its pecuniary, mental, moral and social powers.

The tendency to gregariousness in American cities is in no specific direction more evident than in the medical profession; hence, success is and will continue to be an increasing difficult problem, a circumstance to be reckoned with, no matter what our meaning and ideals as a national profession. This portends in its last analysis the necessity of better training and equipment for every-day duties of the practitioner.

America stands in need of further reform in medical education and the immediate establishment of one authority—one licensing body; and self-created schools must place themselves in a position in which they can worthily assist in the execution of a scheme of higher national medical education. Professional ascendency in future will demand the creation of a homogeneous and adequate standard of qualification for entrance into medical schools.

The relation of social conditions to disease is a topic that is becoming more and more insistent with the reflections that are the natural accompaniment of advancing knowledge.

A backward look reveals an embryo nation steeped in an arduous task, the subjugation of a continent, at the expense of unceasing physical toil. This necessitated an open-air existence, which resulted in a vigorous, hardy race. Then followed the integration of frontier villages, of larger and smaller towns, and life meanwhile became brighter and more piquant. For long generations the abandonment of rural life, the changed habits of living, the enforced pursuit of new and less healthful callings, too often from motives of personal comfort and even social expediency, and the universal tendency to overcrowding in town populations, resulted in a modification of the character and incidence of all leading diseases. It goes without saying that respecting the effects of our social conditions and climate on disease, the particular standpoint of our fathers was radically different from that of their children. Floyd M. Crandall has recently directed forcible attention to the fact "that never have such radical changes been witnessed in the habits of life and in human diseases as those in this country during the last half century."

Fortunately, agencies are at work looking to the socialization of the American agriculturist and the amelioration of the ills due to overcrowding in large municipalities. This is a movement which in the entirety of its scope embraces numerous potent forces whose federation promises to effect in time rural social regeneration. An organized effort has in several states been already initiated, and in the conferences held and in contemplation looking to the betterment of rural life, the co-operation of the medical profession is invited. Modern agencies, as improved highways, the introduction of the telephone, trolley lines, rural mail delivery, are socializers no less than economic facilities. In addition to these physical influences, marked improvement also comes from increased educational opportunities, farm organization and the various functions of the church.

These socializing influences and forces tend to counteract the current of bygone days from the farm to the city; they likewise bid fair to become a factor of first importance in minimizing, if not actually counteracting in due season, the ill effects of over-dense urban populations. It may, however, be remarked that the impoverished classes, especially the great immigrant contingent, will be far less likely to return to a rural environment than the well-to-do, and yet it will shortly affect the social and economic conditions as well as the vital statistics of the wage-earning classes. We may confidently expect a greater physical efficiency, a higher bodily standard, though municipal sanitation will be always required, and remain the principal factor in strengthening the powers of resistance to hostile environment. One point of common agreement is that as a result of the rapid advances in sanitation and improved methods of treatment, there has been a notable decrease in prevalence and fatality of most infective diseases, particularly those more or less fostered by overcrowding (e. g., phthisis, diphtheria, diarrheal diseases, etc.). Three well-defined classes, however, have, according to the census for the decade ending May 30, 1900, distinctly increased; they are cancer, affections of the kidneys and the degenerations, fatty and fibroid. Thus during an increase in the population of 50 per cent. in the United States myocardial degenerations have increased 150 per cent. and certain types of chronic nephritis have also risen in frequency to nearly 200 per cent. The determination of the causes of this rapidly increasing frequency of these morbid states is clearly the task of the medical profession.

Respecting the degenerations—myocarditis, arteriosclerotic changes and kidney diseases—Crandall says: "The power of alcohol in the form of malt liquors to produce degenerate changes is so well known to pathologists that the conclusion is irresistible that the radical increase in these diseases comes largely from changed drinking habits."

The notable increase in these morbid conditions, however, is not due to a single cause, and substantial progress can not result from too much emphasis on any one agency whose undoubted potency remains undemonstrated.

It is probable that a more universal application of refined methods of diagnosis accounts in a measure at least for the apparent disparity in the number of cases of nephritis and myocardial degeneration in recent times as compared with the showing of older statistics.

The census between 1890 and 1900 indicates an increasing prevalence of two additional diseases, in respect to both of which progress in our knowledge has been slow and never encouraging. I refer to diabetes mellitus and lobar pneumonia. The census previously referred to indicates that chronic diabetes mellitus has nearly doubled in point of frequency in a single decade.

While we shall continue to look to the bacteriologic laboratory for the discovery of the definitive cause of this metabolic ailment, and to the pathologist for a mind's-eye picture of the morbid state of the tissues, the data obtainable from an investigation of the manner and habits of life, which exert more or less etiologic influence, are of intrinsic medical importance and would serve as accessory factors in diagnosis as well as straws for the application of measures for treatment.

Although impossible to recognize a boundary line between the "variables of health" and disease in chronic diabetes mellitus, it can not be doubted that abnormalities of the glycolytic functions of the liver and pancreas, associated with inappreciable structural changes (more especially in the cells forming the islands of Langerhans) which interfere with proteid metabolism and the metabolic disturbances, are dependent in large measure on the overuse of the mind, intemperance and irregular habits of body; in a word, on improper modes of living.

Physiology has contributed much to the intricate processes involved in the nutritional diseases. Morbid physiology (general pathology) is most intimately bound up with the modes and predilections of American life, particularly of the so-called privileged classes.

TABLE I.

No.	Age.	Sex.	Nationality.	Accompanying Circulatory Lesions.	Accompanying Renal Lesions.
1	54	Male.	German.	Absent.	Absent.
2	56	Male.	Irish.	Absent.	Acute diffuse nephritis.
3	66	Female.	Irish.	Chronic endocarditis, mitral and aortic.	Chronic interstitial nephritis.
4	35	Male.	American.	Hypertrophy with dilatation.	Chronic interstitial nephritis.
5	68	Male.	American.	Hypertrophy with dilatation.	Absent.

Diseases and conditions that are successfully treated by a correction of the mode of life are apt to be regarded as functional in nature, when, in reality, definite although undiscoverable structural lesions already exist, the foundation of an insidious and progressive disease already laid.

Now it is conceivable that a broader application of data as yielded by vital statistics would render more clearly recognizable the terrible significance of an enlightened public, living in idle acquiescence to positively injurious prevailing customs. A federation of forces, however, in connection with the investigation of special diseases even, is necessary to make this branch of inquiry productive of really important information; for example, the co-operation of committees on vital statistics with the creation of centers under the auspices of a national organization, such as the American Medical Association, would prove effective. I would instance lobar pneumonia, which, as before stated, is increasing in prevalence, as a disease in which the light of future investigation after this method of research would prove preliminary to important discoveries and decisions. Indeed, the local diversity in social conditions and climate in different sections which are far separated by geographical distances in this country, renders such a procedure an absolute necessity. The statistical data gathered by individuals, notable those of E. F. Wells, are of real value, and one point approximately settled is that the death rate by decades during eighty years is practically unaltered—"certainly not decreasing." The census for the decade between 1890 and 1900 shows an increased prevalence of this disease from 186 to 191 per 100,000.

A marked numerical increase in the number of cases of pneumonia has taken place since the advent of epidemic influenza,[1] but this does not account for the slowly rising incidence of the disease during previous non-epidemic seasons. Other reasons have been given for the augmenting prevalence of pneumonia: increased facilities for travel and the tendency for people to congregate (Wells), the highly infectious character of the disease and the neglect of prophylactic measures in crowded centers (Walsh). Among accessory causes of the increased prevalence of pneumonia may be mentioned a change in the prevailing meteorologic conditions. As shown elsewhere the wanton destruction of the native forests has been attended with an exaggeration in the range of variability of such meteorologic conditions as temperature and humidity. It has been long known and universally recognized that this disease bears a vital relation to the seasons, and that the greatest morbidity coincides with the most pronounced climatic changes. It is probable that the increased incidence of the disease will be shown to be dependent in part on augmenting prevalence of visceral degenerations, particularly of the cardio-vascular system and the kidneys. Be it remembered that in a large measure these are the direct or indirect result of an era characterized by undue devotion to business, social excesses and club life, with its attendant unseemly hours and unconcealed conviviality. It must be confessed that the extent to which lobar pneumonia is dependent on these degenerations acting as predisposing factors is imperfectly known, but it can not be doubted that a conservative attitude toward the question accords to them a prominent position among the agencies unfavorably affecting the prognosis, as shown by Table 1.

This table comprises all necropsied cases of lobar pneumonia at the Philadelphia Hospital for a period of 6 years, from Jan. 1, 1896, to March 1, 1903.[2] Out of a total of 275 cases, 250, or about 90.9 per cent., showed cardio-vascular lesions, principally chronic endocarditis and general atheroma of the vessels. A small number of the cases, 14, or 5 per cent., showed acute plastic pericarditis, and 11, or 4 per cent., chronic pericarditis. Renal lesions were recognized in 90.5 per cent. of the totality of cases. Chronic interstitial nephritis was noted in 145, or 52.7 per cent.; chronic parenchymatous nephritis in 50, or 18 per cent., and acute nephritis in 38, or 13.8 per cent. Among the remaining 25 cases was one of renal calculus, another of renal tuberculosis, and in many of the remainder subacute nephritis was noted.

These figures afford strong presumptive evidence that renal and cardiovascular degeneration rank as potent predisposing conditions, and clear and convincing proof that they bear a close and vital relation to the high mortality rate of lobar pneumonia. It should be stated that the patients admitted into the Philadelphia Hospital belong to the pauper element of society and the subjects are principally adults.

The reports of the health departments of leading cities, in particular that of New York, furnish valuable data from which important tentative influences may be drawn, but sure ground can result only from research work of a broader character than has yet been undertaken in this country. From the record of vital statistics of Philadelphia and New York I have compiled two tables (*vide infra* tables No. 2 and 3), which show that pneumonia is more or less limited to centers, and these correspond in the main to the most densely populated areas, with their allied conditions of squalor and poverty.

Pneumonia, like other acute infections that prevail epidemically, shows a wave-like character, on comparing different years for the same locality. Exclusive of epidemic outbreaks there is an evident tendency to a preponderating incidence in overcrowded districts, and among the impoverished classes. Thus the average mortality rate for four years in New York (*vide* Table 2), taking the eight wards which are most densely populated, from the tabular list is 18 per cent.

The fourth, sixth, seventh, tenth, eleventh, thirteenth, fourteenth and seventeenth wards of New York City were embraced in this estimation. In contrast with the figures just given, eight wards representing the most sparsely settled portions of the city of New York (e. g., first, fifth, eighth, ninth, fifteenth, sixteenth, eighteenth and nineteenth) gave for the same period of four years an average mortality of 14.3 per cent.[3] It was observed in the compilation of these mortality statistics that an elimination of the epidemic periods would make the differences in percentage dependent on the population somewhat greater.

In arranging the statistics for Philadelphia I have included only those wards in which the inhabitants were equally distributed throughout the entire ward. Per contra, wards having large area and a low population, per acre, but this population located in certain sections of the ward only, have not been included. Thus the following wards became available for the purpose of contrasting those giving the highest with others showing the lowest mortality: First, second, third, fourth, fifth, sixth, seventh, ninth, tenth, eleventh, twelfth, thirteenth, fourteenth, fifteenth, sixteenth, seventeenth, eighteenth,

TABLE II.

Ward.	Area in Acres.	Population U.S. Census of 1900.	Population per Acre.	Percentage of Deaths from Pneumonia.

* Population and deaths occurring in Almshouse (Twenty-seventh Ward) do not appear in this table. Deaths in Almshouse, 1,637.

Forty-one (41) per cent. of deaths from pneumonia occurred after the age of 40 years.

nineteenth, twentieth, twenty-eighth, twenty-ninth, thirtieth, thirty-first, thirty-second and thirty-seventh.[1] The eighth ward was not included on account of being inhabited principally by a better-to-do class and on account of containing the Pennsylvania Hospital, the former condition lessening the liability of pneumonia, while the latter institution named would tend to increase the mortality from this disease since many of its patients come from the third, fourth, fifth and sixth wards. The portion of the city west of the Schuylkill River was excluded from this computation for similar reasons.

Out of the 25 wards included in our figures I have estimated a percentage of deaths from those showing the most dense population per acre, allowing for the location of hospitals, homes, etc. (e. g., second, third, fourth, seventh, thirteenth, seventeenth and nineteenth wards), and I find the percentage of deaths from pneumonia to be 12.8 per cent. Those wards showing less dense population, the first, ninth, tenth, sixteenth, twenty-eighth and thirty-second, gave an average of 9.5 per cent.

The second, third and fourth wards were occupied largely by foreigners (Italians, Russians) and showed the highest percentage of deaths from pneumonia, while the seventh ward, which contains a large colored population, also shows a very high death rate.[5]

As shown by MacDougall's statistics, unfavorable occupational conditions probably have less effect in causing pneumonia than phthisis. In my own investigations it was observed that divisions of Philadelphia having an industrial population modestly though comfortably housed furnished a death rate but little in excess of that of the sections inhabited by the well-to-do. The whole subject of occupational diseases, eminently important to the medical world, is closely united with the social and economic conditions of the wage-earning classes, but its consideration here would lead me too far a-field.

REFERENCES.

1. Phila. Hospital Reports, vol. 14, p. 57, 1896, by the writer.

2. For permission to examine and employ the records of this hospital, the writer is indebted to Dr. J. V. Shoemaker, president of the Board of Charities and Corrections.

3. The writer desires to acknowledge, with thanks, the kind aid of Dr. William H. Guilfoy, registrar Department of Health, N. Y., in furnishing data for the above table.

4. The following wards have not been included in the estimation of the lowest percentages for the following reasons: The Twelfth Ward, while it shows a low population per acre (86), has a number of hospitals and homes which contribute largely towards its high death rate from pneumonia. The Second and Third Wards show a population of 18 and 19 per acre; there are but few children under 5 years and few aged persons living in these wards, and this lessens the mortality from pneumonia. The Twenty-first and Twenty-second wards, because they are occupied mostly by the well-to-do classes. The Fifteenth, while it has been included in my calculation, contains a large colored, Italian and French population.

5. My acknowledgments are here due to Dr. L. Napoleon Boston for assistance rendered in connection with the statistics gathered in Philadelphia.

Eye Affections in Egypt.—Baudry, professor of opthalmology at Lille, on his recent visit to the Egyptian Medical Congress, made a special study of the endemic eye affections, for which the country is notorious. He reports in the "Nord Méd." of January 15 that the ocular lesions there are the same as elsewhere and that there is no special morbid entity peculiar to the country. The famous Egyptian ophthalmia is merely trachoma complicated by a catarrhal or purulent condition of the conjunctivæ, and does not differ from such conditions anywhere. The climatic and hygienic conditions of the country explain the prevalence of eye affections and the frequency of contagion. Some ideas of hygiene have already percolated among the masses and the number of cases of trachoma has materially diminished of late years.

Preliminary Note.

DIAGNOSTIC VALUE OF BLOOD PRESSURE DETERMINATIONS IN THE DIAGNOSIS OF TYPHOID PERFORATION.

GEORGE W. CRILE, M.D.
CLEVELAND, OHIO.

The highest systolic pressure in uncomplicated cases, and with normal arteries, as measured by a Riva-Rocci sphygmomanometer in 115 cases of typhoid, was 138 mm. mercury; the lowest, 74 mm.; the mean in the first week was 115; the second, 106; the third, 102; the fourth, 96; the fifth, 98.

In 20 cases of acute peritonitis, recorded by the same observer with the same instrument in otherwise similar cases, the highest systolic pressure was 208 mm. mercury; the lowest, 156; the mean, 166 mm. The mean pressure of all the typhoid was 104 mm.

In 5 cases diagnosed typhoid perforation, in which blood pressure determinations were made, 4 were verified either by operation or autopsy. The case not operated on was a typical one. The pressure rose from 116 mm. to 190 mm. during four hours. The second case, a lad of 12, was admitted to Lakeside Hospital in general peritonitis. Blood pressure was 105; Widal reaction was positive. Immediate operation was performed and a perforation found. Later the abdominal symptoms of peritonitis disappeared. The blood pressure fell to 80 mm. On the eighth day infection passed through the thinned wall of another ulcer, causing peritonitis; blood pressure then rose promptly from 84 mm. to 110 mm.

In the third case, a patient in the ward at Lakeside, developed a slowly forming perforation, blood pressure rose from 116 mm. to 165 within two hours. The pulse in the meantime had but slightly increased. At operation a small perforation and diffuse peritonitis were found.

The fourth case, that of a physician who entered Lakeside with general peritonitis, blood pressure was 165; no operation. Autopsy revealed perforation and diffuse peritonitis.

The fifth case was one of typical perforation, blood pressure 208 mm. At operation perforation and diffuse peritonitis were found.

The blood pressure in the perforation cases assumed the high level attending peritonitis from other causes.

The Lay Press as Physicians' Censors.

A new method of restraining the physician who is anxious for newspaper fame has been discovered. The Indian Territory Press Association, in session at Muscogee April 25, discussed the proposition of excluding from their newspapers the names of physicians who consider it contrary to the ethics of the profession to advertise and pay for the same, but who are willing or desirous of having their names mentioned in connection with operations, interesting cases, etc. We regret to learn that the resolution to take this action was finally voted down, having, however, excited a warm dispute. The Indian Territory Press Association is on the right track; the measure ought to pass, not only there, but elsewhere. The press has here far more power than the medical societies can exert. Such a measure would relieve from temptation many an erring physician and from anxiety many a grieved observer.

SATURDAY, MAY 9, 1903.

THE INVESTIGATING FORCE AT THE ROCKEFELLER INSTITUTE.

In a previous number of The Journal we ventured to comment on the drawings of plans for the buildings projected by the Rockefeller Institute for Medical Research. Of much greater importance, however, for the success of the institute is the policy which will be adopted in the selection of the investigative force which will work there. Mistakes with regard to the construction of buildings would be deplorable; serious errors in judgment in the choice of the men who are to undertake the scientific research of the institution, or in the organization of the staff, might prove fatal to its welfare. In this connection there are one or two points to which we desire to call attention.

We approve, and we believe that there is general approval, of the choice of a scientific director made by the board of directors. Dr. Flexner seems to us to be the logical man for the place. But we shall be, and we believe others will be, deeply interested in the method which is followed in the appointment of the investigating force as a whole.

Either one of two plans may be adopted. It may be decided that the institute shall be developed as a unit centering in the personality of the scientific director, whose province it will be to determine the problems to be undertaken and the methods by which their solution is to be approached; in this event the members of the staff would consist of a group of men, skilled in diverse directions, whose functions it would be to follow the leadership of the director, at least in a general way. This is the kind of organization that obtains, so far as we can learn, in the Institute for Experimental Therapy in Frankfort, over which Paul Ehrlich presides with success. The other plan which might be chosen would be that in which the scientific director, with the sanction of the board, selects a number of eminent men, each to have autonomous charge of a department of work in the institute, say one in physiologic chemistry, one in physiologic physics, one in experimental therapy, one in experimental surgery, one in the field of enzymes, etc., the scientific director to have charge of one of the departments himself and to stand in much the same relation to the men in charge of the other departments that the president of a modern university stands to the heads of departments in the university. This second plan of organization corresponds in the main to that adopted in the Pasteur Institute in Paris.

While each of the two modes of organization may lead to successful results, it appears to us that the second possesses many advantages over the first. For, in the first plan, it might be exceedingly difficult for the director to secure appointees who would approach the level of his own mental caliber; there would be danger that the staff would be made up, very largely at any rate, of assistant natures, lacking in power of original thought and initiative; indeed, the success of this plan would be in large part dependent on the willingness of the staff to faithfully carry out the ideas and instructions of the director and to stifle their own tendencies to tangential excursions and suppress their own ideas regarding the overcoming of obstacles when these were opposed to the director's plans. Conditions such as these, while important and desirable for the aspiring scientist in his period of pupillage, are insufferable when that period has been passed. The second plan, on the other hand, permits of a much broader development, and it is, of course, the much more costly plan of the two. Here each head of a department may be a man of mental powers equivalent to or in many ways even superior to those of the director; the research along each of various lines may be guided by an expert; younger men undertaking investigations may begin under conditions of pupillage and be gradually led into positions of ever-increasing independence; the occupants of the higher positions have all the advantages of companionship and consultation with their colleagues of allied subjects with none of the restraints or limitations which a rigid monarchial organization imposes. The scientific director must, it is true, in this instance, be a man of large personality, of wide sympathies, above petty jealousies, and more interested in the advance of medical science than anxious for the recognition and forwarding of his own reputation. It is only this kind of a man who is not afraid to have strong men near him.

It seems probable that the Rockefeller Institute for Medical Research will not be compelled, for financial reasons, to adopt any mode of development other than the best. The Journal hopes that when a decision regarding details of organization has been reached it will be found that a scheme has been devised which will bring together an active group of skilled investigators and which will combine all the advantages of concentrated effort with the greatest possible opportunity for individual freedom of thought and experimentation.

REMARKABLE PROPERTIES OF RADIUM.

Though only discovered in 1898, the new metal, radium, bids fair to set the physical-chemical world agog. The prospect of securing energy for nothing has stimulated the imagination of a certain number of human beings from time immemorial, but the nearest approach to the mythical "perpetual motion" thus far made would seem to be that presented by the phenomena manifested by radium and its salts. It was startling enough to be told that radium can give out light continuously

THE SO CALLED "KOCH LUNG CURE" FRAUDS

The magazine *Physical Culture* has published a very interesting expose of the different so-called Koch lung-cure institutes and sanitaria, which are pretending to be connected with the famous Berlin scientist. The exposure is certainly a complete one and should go a long way to prevent this sort of quackery and imposition on the public. This magazine, while we can not endorse it in all of its contents, is doing excellent work in this particular and we hope that it will keep on and do still more. There is a large field for this kind of work and they seem to have the author in Mr. Gerald Keating, who knows how to do it well.

DEFEAT OF EDDYISM IN PENNSYLVANIA

Sometime since, as the readers of The Journal are aware, a charter was refused to the Eddyite organization in Philadelphia by a Pennsylvania judge on the ground that it was a corporation for profit and against public policy. The case has been carried to the Supreme Court and a decision just received. The findings of the lower court are confirmed. The Supreme Court holds that the state regulates the practice of medicine and requires certain qualifications in its practitioners. While faith and prayer may be of use, common sense as well as public policy demands that other measures be taken in certain cases. The decision fixes the status, or rather the non-status of Eddyism in Pennsylvania; as a healing cult it has no standing whatever, for which fact the citizens of that commonwealth are to be congratulated.

THE W. C. T. U. AND PATENT MEDICINES

We have occasionally seen in our contemporaries criticisms of the W. C. T. U. for not fighting the drink evil along the line of patent medicines. The charges have been made that leaders of the said body have been induced to endorse for popular use some strongly alcoholic preparations, alleged to be of a medicinal nature. In a recent communication to the *Dietetic and Hygienic Gazette* for May, Mrs. Martha M. Allen, who has charge of the W. C. T. U. work in this particular line, shows that they have not been inactive in this particular, but have carefully obtained official analyses of large numbers of patent medicines and distributed pamphlets and books exposing them to such an extent that they have been threatened with legal proceedings on the part of the manufacturers. These threats, of course, were futile, in view of the fact that the analyses given were made by state officers and published as such. In 1898 the Woman's Christian Temperance Union, with the assistance of the editors of several high-grade pharmaceutical journals, issued a pamphlet entitled "The Dangers and Harmfulness of Patent Medicines," thousands of copies of which were distributed. The work is still being continued along this line. It is not surprising that unsuspecting reformers should sometimes be misled to give their names to what they would not with full knowledge have endorsed, and we can not accuse them of anything more than a lack of consideration. It is simply a matter of unsuspicious ignorance. This is the reason why we have so many clergymen and other good people endorsing patent medicines, and we believe that no one would be more sorry than they for any evil they may have thus unwittingly aided. The question might be asked whether we as physicians always do our duty in regard to informing patients who may be misled as to these nostrums. It is satisfactory, however, to know that an organization which has been charged with neglecting this matter has by no means been guilty of such negligence, but has been an active factor in the publication of the dangers of alcoholic patent medicine dosing.

ANOTHER GOVERNOR'S VETO

Some time ago we had occasion to notice what seemed to us a very poorly advised veto of a medical practice act by the then governor of Colorado, and we commented rather plainly on the reasons given in the veto message. They have changed governors in Colorado since that time, but unfortunately the precedent seems to have been set that is slavishly followed. The last medical act which recently passed the house and senate and was supported by the medical profession in the state has also been vetoed by the governor. It was not a radical measure; in some respects we think it might have been better by having been made more radical, but it seemed to be altogether too much so for the administration. The governor's ideas on the subject are rather curious. He remarks that reliable statistics show that the death rate of Colorado is as low as it ever has been, therefore medical matters are just where they ought to be and the proposed law was useless and likely to make things worse. He says, guided by the late experience of similar legislation in other states, the conclusion is irresistible that "all such legislation has a tendency to restrict the citizen in the employment of whomsoever he pleases in the treatment of his diseases," and goes on further to say that it will build up a medical trust made up of certain schools, to the exclusion of others equally meritorious, including among the latter, we presume, faith healers, osteopaths, Dowieites, Eddyites, *et id omne genus*. The statistical method of showing the expense to a community from evil is a popular one, and we wish that some one would get up the statistics of the money spent in Colorado on this class of practitioners, especially adding the amount given to itinerant frauds who go through the country and rob the innocent and confiding public of the state. We believe a true statement of things would be a little appalling to the governor who is so fond of letting the individual employ whomsoever he pleases unrestricted. The Colorado contributions to quacks, frauds and pretenders thus favored by the governor will, we presume, go on and grow until the time may come when a little common sense will penetrate the executive cranium and allow a reasonable medical practice act to go into force. There are just as good arguments in favor of the itinerant gambler, if every citizen has a right to lose his money in the way he pleases, as there are in favor of the irregulars championed by the governor of Colorado. The common sense to be found in the message of Governor Wells of Utah,[1] accompanying his veto of the osteopathic bill, is in happy contrast.

---

[1] The Journal A. M. A., April 25, p. 1156.

VACCINATION AND SMALLPOX.

As was told in The Journal last week, in our special telegraphic report from Boston, the etiology of smallpox is now known through the work of Drs. W. T. Councilman, Geo. B. McGrath and W. R. Brinckenhoff. It is a sporozoon first suggested by Guarnieri as the cause of variola and named by him *Cytoryctes vacciniæ*. On Monday evening, at another large meeting of medical men, at the Boston Medical Library (soon to be the Academy of Medicine), Dr. E. E. Tyzzer described his elaborate work on the organism of vaccinia, performed during the spring and summer of last year. Experiments were made by inoculating rabbits' corneas with vaccine virus and with the contents of the pustules of variola. Microphotographs showed every stage of the asexual cycle of *Cytoryctes vacciniæ* in the cases in which virus was inoculated, the sporozoa appearing in sixteen hours in the epithelial cells, and every cell containing them by the end of the third day. Dr. Tyzzer, like Dr. Councilman, is sure that the organism of the two diseases, vaccinia and variola, is identical, the two results differing for the reasons described above. This elaborate research brought to so successful a result appears as a model of no little significance for those who would accomplish results of real scientific worth. It illustrates, as few recent discoveries illustrate, the benefit to be derived from systematic and co-ordinated endeavor, under the guidance of a wisdom which is always more than mere learning. Several factors combined to the result. First, there was an epidemic of smallpox; second, a city board of health, imbued with the true scientific spirit, gave the widest possible privilege and opportunity for the collection of pathologic material; third, an adequate directing mind; fourth, a number of younger men who knew neither fatigue nor fear in pursuit of the common good; fifth, adequate financial means, and sixth, pervading all, the tireless energy which kept and which still keeps, for future further gains, the research up in all its laborious and infinite detail. These fruitful elements should be present to-day in every large city of the land—disease, a board of health, some earnest medical scientists, money from some one of the great funds now available and the energy of discovery. Combining these factors, why should not some other unsolved problems be compelled to give up their hidden solutions?

Medical News.

ILLINOIS.

Chicago.

Personal.—Dr. Albert H. Hoy and family have returned from California.——Dr. Frederick Mueller gave a dinner, April 28, in honor of Dr. Adolf Lorenz.

Heavy April Mortality.—During April 2,628 deaths were reported, equivalent to an annual death rate of 16.96 per 1,000. Not since the year following the great fire has there been such a prevalence of the graver diseases.

Women Want Hospital.—At the meeting of the alumnæ of the Woman's Medical College it was proposed by Dr. Mary Coons that a hospital for women, to cost $500,000, be erected near Jackson Park. A committee of five was appointed to report on a plan for the enterprise.

Deaths of the Week.—During the week ended May 2, 637 ths were reported, an annual mortality per 1,000 of 17.62. umonia again heads the list with 167 deaths; consumption comes next with 65; violence and heart disease follow, each with 39. Nervous diseases caused 38 deaths; measles 28, whooping cough 5, scarlet fever 4 and smallpox 2.

How Not to Lose Diphtheria Patients.—The department of health, in its latest bulletin, makes the following statements regarding diphtheria:

> There are numerous physicians who treat yearly a large number of diphtheria cases who have not lost a patient from this disease for years. Their inflexible rule is to take a culture at the first visit and to administer antitoxin at once when the diphtheria bacilli are found.
>
> For a physician to treat a patient with an acute inflammation of the throat for days without a microscopic examination is little short of criminal neglect. The essentials in the treatment of diphtheria are an early diagnosis and the prompt administration of antitoxin. Physicians who are prepared in these essentials are seldom called on to give a death certificate.

The Captain of the Men of Death.—Under this title the department of health characterizes pneumonia:

> Pneumonia remains as the opprobrium of the medical profession. Its treatment, notwithstanding more than one vaunted antipneumococcic serum, is as unsatisfactory as ever, while its increasing ravages make all other acute infectious diseases relatively insignificant.
>
> The commissioner calls attention to the fact that of the total of 2,628 deaths in April, 604 were caused by pneumonia and only 283 by tuberculosis. This is an excess of 113.4 per cent. of pneumonia deaths over consumption deaths, and, while the deaths from consumption have increased 30.4 per cent. in actual numbers over those of April, 1902, the deaths from pneumonia have increased 11.1 per cent. this April over last.

The department repeats its warning to physicians and those in charge of the sick, urging the combating of the spread of the disease by cleanliness, ventilation, etc.

MARYLAND.

Baltimore Vital Statistics.—Two new cases of smallpox were reported last week and 36 of diphtheria. Among the deaths consumption led with 34, pneumonia and Bright's disease following with 16 each.

Medical Banquets.—The annual banquet of the Alumni Association of the College of Physicians and Surgeons was held April 27. Prof. William Royal Stokes was toastmaster. The menu was written in prescription form, the courses being all in Latin.——The sixth annual banquet of the Baltimore County Medical Association will be held in Baltimore, May 13.

Personal.—Dr. Norman M. Harris, associate professor of bacteriology in the Johns Hopkins Medical School, Baltimore, has accepted the position of first assistant in bacteriology at the University of Chicago.——Dr. George Warner Miltenberger, Baltimore, has recovered from the operation done on him several weeks ago at the Union Protestant Infirmary.——Dr. Frank Oldham Miller has completed his term as resident physician in Bay View Asylum, Baltimore, and is now settled in practice at Uniontown.

P. and S. Commencement.—At the commencement of the College of Physicians and Surgeons, Baltimore, April 30, 76 out of 79 candidates for the degree received diplomas. The first gold medal was awarded to Dr. Samuel T. Darling, Maryland; the second to Dr. T. J. Cummings, New Jersey; the third to Dr. F. W. A. Mayer, New Jersey, and the fourth to Dr. W. S. Evans, Utah. The following received honorable mention: Drs. George E. Merrick, Pa.; Frank H. Cutler, Utah; George L. Fawcett, Ala.; A. W. Deal, Pa.; T. J. Brothers, Ala., and E. H. Cohoon, Nova Scotia. Appointments were announced as follows: Dr. L. J. Owen, resident physician, City Hospital, with Dr. Z. P. Henry, and S. L. Page, associates, and Drs. W. S. Evans, A. W. Deal, A. C. Biddle, Major M. Allen, and C. W. Lurking, assistants. Dr. T. J. Cummings was made assistant to Dr. N. G. Keirle of the Pasteur Institute, and Dr. Samuel T. Darling was appointed resident pathologist. Drs. Wright S. Sudler, A. Ferdinand Ries and George F. Sargent were appointed resident physicians at Bay View Asylum. Drs. C. G. Laslie and J. Plummer Cole were appointed resident physicians at the Maternité Hospital.

MASSACHUSETTS.

War Against Mosquitoes.—The mosquito war is on in Brookline, where $1,000 will be expended this year in "petrolizing" pools, catch-basins, etc. Worcester will spend $3,000 and Fairhaven $300 for the same purpose.

Smallpox in Adams.—An advanced case of smallpox was discovered at Adams, May 1, and the 650 children in the public schools were promptly vaccinated, as the patient had undoubtedly exposed a number of children living in the house.

Marathon Racers' Hearts.—The eight physicians who examined the Marathon runners before and after their twentymile race, April 19, have reported no unusual findings except that the two cases of severe exhaustion noted were due to the unwise use of alcohol.

Hospitals Benefit.—By the will of John W. Shapleigh of Brookline, the Free Hospital for Women, the New England Deaconesses' Home and Training School Hospital will largely benefit, the amount being a proportionate part of a trust fund left to his wife and daughter.

Personal.—Prof. O. T. Wadsworth has resigned the chair of ophthalmology at Harvard Medical School.——Arthur I. Kendall, Ph.D., will work, as fellow of the Rockefeller Institute for Medical Research, this summer on the Boston Floating Hospital, under the supervision of Dr. Simon Flexner, in his study of the Shiga bacillus and the serum treatment of infantile diarrhea.

For a Control of Tuberculosis.—Thirty-five hundred cases of tuberculosis reported to the board of health of Boston in the last three years has aroused the public interest, and the Boston Association for the Relief and Control of Tuberculosis has been formed, with Dr. Edward O. Otis, president, Dr. Arthur K. Stone, vice-president, Miss Alice L. Higgins, secretary; George S. Mumford, treasurer, and a strong executive committee. The organization seeks to educate the people in treatment and in prophylaxis.

More of Councilman.—The Medical Library meeting of May 4 was a fuller exposition of the studies of Dr. Councilman and his associates of smallpox. Dr. Ralph L. Thompson presented a full statement of his new methods for determining the bacteriolytic complement content of the blood serum, which he has most carefully worked out in variola in his research, under the auspices of the Rockefeller Institute. This is undoubtedly a great step forward in the revelation of an index of the vitality of a patient and, hence, the progress of his disease. Dr. E. E. Tyzzer told of his studies of vaccinia, and Dr. William T. Councilman again demonstrated and described his discovery, the protozoon of smallpox.

NEW JERSEY.

Physician Wins Suit.—The case of Hiram J. Shoemaker against Dr. Henry W. Elmer, Bridgeton, for alleged wrongful treatment of an injured shoulder, was decided in favor of the defendant.

Osteopath Bill Fails of Passage.—A bill to establish a board of examiners in osteopathy who would have power to examine and license persons to practice osteopathy in the state, met the determined opposition of the legislative committee of the Medical Society of New Jersey, and was strangled in the senate committee.

The Legislature's Good Record.—The legislature which has just adjourned has left a good record behind it in general and, so far as medical legislation, has done particularly well. A bill was passed granting $200,000 to the State Sanatorium for Tuberculosis, a site for which has already been secured in Hunterdon County. The erection of the buildings will be pushed with all possible dispatch, under the architectural direction of George B. Post of New York City.

New Requirements for Medical Licenses.—The State Board of Medical Examiners announce that after July 4 the following changes in the requirements for a New Jersey license will go into effect:

1. The date of examination will be the third Tuesday and Wednesday in June and October.
2. The academic requirements will be a certificate or diploma, issued after four years of study, either in a normal, manual training or high school of the first grade in this state, or in a legally constituted academy, seminary or institute of equal grade, or a student's certificate of examination for admission to the freshman class of a reputable literary college or an academic education considered and accepted by the state superintendent of public instruction as fully equivalent.
3. The medical requirements will be four full school years of medical study of at least nine months each, including four satisfactory courses of lectures of at least seven months, in four different calendar years, in a legally incorporated medical college or colleges, prior to receiving the degree of doctor of medicine.

NEW YORK.

Insane Hospital Improvements.—The bill introduced by Mr. Rogers, appropriating $1,070,000 for improvements to the state hospitals for the insane, has been passed by the legislature.

Filtration Plant Completed.—The filtration plant for the water supply of Cornell campus at Ithaca is completed and the water was turned into the main. This is the plant for which Andrew Carnegie has paid.

Presentation to Dr. Knight.—On the occasion of his seventieth birthday anniversary, Dr. Charles Calvin Knight invited the members of the medical staff of the Peekskill Hospital and their wives to dine with him. His guests surprised Dr. Knight by presenting him with a magnificent silver punch bowl and ladle.

For Consumptive Camp.—The assembly, on April 21, failed to pass the Goodsell-Bedell bill, requiring the consent of county and town authorities for a camp for consumptives. The bill, while of a general nature, was intended to prevent the establishment of a hospital camp for New York City consumptives at Central Valley, Orange County.

Lectures to State Alienists.—Dr. Adolf Meyer, director of the Pathological Institute of the New York State Hospitals on Ward's Island, has finished the third course of instruction to the physicians of the fourteen state hospitals. These three courses of lectures and clinics have been given by himself and his assistants at Ward's Island during the past winter. In all, 61 physicians belonging to the staffs of the state hospitals at Buffalo, Utica, Gowanda, Middletown, Rochester, Ogdensburg, Poughkeepsie, Brooklyn, Central Islip, Kings Park, Matteawan, Dannemora and New York City have been in attendance.

Application Against Raybrook Denied.—The attorney general has refused to order proceedings to declare void the purchase of the lands at Raybrook, Essex County, as a site for a state consumption hospital. The basis of the opposition to the purchase is that it is contrary to the constitution, which provides that forest preserve lands shall be forever kept as a wild forest. The attorney general holds that the power to locate the institution involved a decision by the governor and that the constitution did not prohibit the location of the hospital on the lands in question and that the selection of the site, being an executive function, the courts would not presume to review its correctness.

New York City.

Bequests to Hospitals.—By the will of Adolph Openhym, $5,000 is left to the Mount Sinai Hospital and $5,000 to the Montefiore Home for Chronic Invalids.

No quarantine against Cuba will be enforced unless yellow fever appears at Cuban ports. This announcement has already been made as regards Florida and Louisiana.

Awarded Fifteen Per Cent.—In the suit for $25,250 brought by Dr. John B. Acken against the estate of the late William R. Clarkson, the jury returned a verdict for $400.

Found Guilty of Manslaughter.—Convicted by a jury of being responsible for the death last September of Miss Agnes Lynch, Dr. Henry C. Hibbe, a physio-medical practitioner, was found guilty of manslaughter in the first degree, April 18. A sentence of twenty years' imprisonment may be imposed.

Buffalo.

Commencement.—The medical department of the University of Buffalo held its fifty-seventh annual commencement May 6. Degrees were conferred on 40. The alumni association held its annual meeting on the same day, at which the classes of '53, '63, '73, '83 and '93 held reunions. At the afternoon session Dr. William T. Sedgwick, professor of sanitary science in the Massachusetts Institute of Technology, Boston, presented the subject of protection of the public health by the filtration of water supplies, illustrated by stereopticon. A banquet was held at the Iroquois in the evening.

Personal.—Dr. William G. Taylor has been appointed to the medical staff in the children's department of the St. Mary's Infant Asylum.——Dr. William C. Krauss has been reappointed a member of the board of visitation for the Buffalo State Hospital.——Dr. Montgomery A. Crockett, who has been at Pinehurst convalescing from a severe illness, has returned to Buffalo and resumed his practice.——Drs. Hibbert Roberts, Edwin A. Riesenfeld, W. S. Goodale and Albert J. Harris have been appointed resident physicians at the German Hospital.——Dr. F. J. Carr will spend several months in Europe.——Dr. William J. Bissell, major of the Seventy-fourth regiment, and Dr. Frederick Busch, of the Sixty-fifth regiment, have been appointed medical officers of the New York State Provisional regiment, which escorted Governor Odell to the dedicatory exercises of the Louisiana Purchase Exposition at St. Louis.

GENERAL.

Professor Hans Kehr, the famous surgeon of Halberstadt, Germany, has come to the United States, it is said, at the

Charles C. Reed, Lincoln, treasurer, and Dr. James Lowrie, Lincoln, delegate to the Illinois State Medical Society.

State Society of Iowa Medical Women.—The medical women of Iowa met in annual session at Sioux City, April 14 and 15, and elected the following officers: Dr. Jennie McCowen, Davenport, president; Drs. Kate A. Mason-Hogle, Mount Vernon, and Lenna L. Meanes, Des Moines, vice-presidents; Dr. Anna Burnett, Mount Pleasant, secretary, and Dr. Agnes Eichelberger, Sioux City, treasurer.

Washington County (Ark.) Medical Society.—At the annual meeting in Fayetteville, April 14, the following officers were elected: Dr. William B. Welch, Fayetteville, president; Drs. John Young, Springdale, and E. G. McCormick, vice-presidents; Dr. Charles M. Robinson, Dutch Mills, secretary; Dr. Robert R. Dinwiddie, Fayetteville, librarian, and Dr. Frank B. Young, Springdale, delegate to Arkansas Medical Society.

Rock Island County (Ill.) Medical Society.—At the annual meeting in Rock Island, April 14, the following officers were elected: Dr. William R. Freek, Cordova, president; Drs. Charles C. Carter, Rock Island, and Lewis D. Dunn, Moline, vice-presidents; Dr. Thomas J. Lamping, Moline, secretary; Dr. Louis Ostrom, Jr., Rock Island, treasurer; Dr. George L. Eyster, Rock Island, official reporter, and Dr. Albert M. Beal, Moline, delegate to the Illinois State Medical Society.

Lewis County (N. Y.) Medical Association.—At the annual meeting held in Lowville, April 13, Dr. Alexander H. Crosby, Lowville, was elected president; Dr. George H. Littlefield, Glenfield, vice-president; Dr. Leroy W. King, Lowville, secretary; Dr. Charles E. Douglass, Lowville, treasurer. Dr. Alex. H. Crosby was chosen member of the nominating committee of the First District Branch of the New York State Medical Association. As fellow to the New York State Medical Association Dr. Charles E. Douglass was chosen; alternate, Dr. Ira D. Spencer, Croghan.

Northwestern Wisconsin Medical Association.—At the annual meeting, held at Stevens Point, April 14, the following officers were elected: President, Dr. Douglas L. Sauerhering, Wausau; vice-presidents, Drs. Karl W. Doege, Marshfield, Levi H. Pelton, Waupaca, and Frank A. Southwick, Stevens Point; secretary and treasurer, Dr. Carl von Neupert, Jr., Stevens Point, and censor for three years, Dr. William W. Gregory, Stevens Point. Hereafter, this association will constitute a district of the Wisconsin State Medical Society, and will comprise Portage, Waupaca, Waushara, Clark, Marathon and Wood counties. Quarterly meetings will be held at Waupaca in July, at Wausau in October, at Grand Rapids in January, and the next annual meeting at Stevens Point in April, 1904.

Kentucky State Medical Society.—At the annual meeting held in Louisville, April 22, 23 and 24, 424 members were registered. It was reported that the membership of the society exceeded 1,600. Lexington was selected as the meeting place for 1904. The following officers were elected: President, Dr. Steele Bailey, Stanford (secretary for 18 years); vice-presidents, Drs. John F. Reynolds, Mount Sterling, Milton P. Creel, Central City, and Frank P. Strickler, Elizabethtown; secretary, Dr. James B. Bullitt, Louisville (for five years); treasurer, Dr. William B. McClure, Lexington; orator in medicine, Dr. Joseph B. Marvin, Louisville; orator in surgery, Dr. Philip H. Stewart, Paducah, and delegates to the American Medical Association, Drs. J. N. McCormack, Bowling Green; Ap Morgan Vance, Louisville, and Isaac A. Shirley, Winchester.

FOURTEENTH INTERNATIONAL CONGRESS OF MEDICINE.

Held in Madrid, Spain, April 23-30, 1903.

President Julian Calleja y Sanchez presiding.

[By Cablegram from Our Special Correspondent.]

[Continued from page 1231.]

MADRID, April 30, 1903.

Fuller reports have been mailed.

Section on Medicine.

Professor Lorand, Carlsbad, in a paper on "Diabetes, Acromegaly and Basedow's Disease," spoke of their related pathogenesis. Diseases of the vascular glands are often associated with the glycosuria of Basedow, and glycosuria is invariably associated with hyperactivity of the thyroid body as in chlorosis, poisonings, lactourea and pregnancy. Thyroidin produces it. Marasmus, myxedema and hereditary syphilis are never associated with glycosuria. True atrophy of the thyroid is rare in infancy.

DISCUSSION.

Drs. Castellvi, Madrid, and Parkinson spoke, agreeing with the points made.

Professor Lorand said that diabetic patients are improved by new conditions producing thyroid atrophy, such as cancer or tuberculosis of the thyroid. Hypertrophy is rare in tuberculous abscess. There is swelling of the gland in infections. An antibacterial function was inferred from the action of the gland *in vitro*. Secondary thyroid atrophy in marasmus produces an indurate edema like myxedema and there is a similar loathing for meat.

Clinical Forms of Hyperchlorhydria.

Dr. Thorena, Madrid, said that this condition is only a symptom of some functional, organic or constitutional disease. Its treatment is chiefly symptomatic and rather unsatisfactory, and relapses are frequent. The diet should be albuminous. Condiments should be omitted. Alkalies are useful. Gastroenterostomy may be required in severe cases with myasthenia, dilatation and inability to diet.

DISCUSSION.

Dr. Maragliano, Naples, protested that the condition was invariably functional and subject to nervous influences. The symptom is controllable medically and operation is absolutely contraindicated. He thought that the profession commonly overestimates the importance of HCl.

Luetic Arthritis.

Professor Singer, Vienna, described this condition, which he said was found in the tertiary stage of syphilis. The character of the process is a torpid thickening of the capsule and of the periosteum accompanied by exostoses. It may last for years without much functional disturbance; the latter is usually slight. Diagnosis is to be made in most cases by the absence of fever, and by the exclusion of an associated endocarditis or gonorrhea. The "mixed treatment," he thought, secured the best results.

Section on Pediatrics. Discussion of Artificial Feeding.

Professor Concetti, Rome, emphasized that the artificial feeding of infants was inadvisable, but occasionally became necessary. It is inadvisable because the natural milk of the mother is never replaced by the most perfect substitute, while sterilization of cow's milk and other artificial foods destroys their susceptibility to the action of the digestive ferments and renders assimilation imperfect.

DISCUSSION.

Dr. Raimondi, Paris, said that he had been able to secure aseptic milk for the use of 200 children from birth to two years of age. He described his method, which was to have the udders of the cows and the hands of the milkers thoroughly washed in a 1-1,000 solution of bichlorid. He did not have the milk itself subjected to sterilization or alteration, but it was given to the children within 20 minutes after it came from the cows. This plan had met with almost invariable success as no digestive disturbance traceable to the food was found among the infants. General congratulations were offered Dr. Raimondi.

Scarlatina.

Dr. Moser, Vienna, described the results of his scarlet fever serum. He said that 142 children had received treatment. The serum was obtained from horses which had been immunized by a mixture of cultures of streptococci and the heart blood of scarlatina. Seven months were required to complete the immunization; 150 c.c. produced an exanthematous fever. The use of the serum counteracts the constitutional vomiting and the delirium reduces the pulse and temperature in less than twenty-four hours. Its administration should be begun as early as possible in order to prevent the occurrence of angina and nephritis. These complications have been markedly reduced by its use and the mortality lessened one-half. Agglutination of the scarlet fever cocci is obtained in dilutions of 1 to 250,000.

been inefficacious in a suspected case, laparotomy is indicated. For benign stenosis, operation affords immediate relief and has no greater mortality than herniotomy. In hour-glass contraction and painful adhesions this procedure gives good results. For the acute hemorrhage of ulcer Dr. Hartmann recommends operation only in those cases complicated by pyloric stenosis, with gastric unrest; here gastroenterectomy is the best sedative and hemostatic. Ulcers which remain painful in spite of treatment, gastrosuccorrhea and rebellious hyperchlorhydria, if accompanied by the pyloric syndrome, probably indicate an ulcer at the outlet, and demand operation.

General Sessions—Immunization of Man Against Tuberculosis.

Prof. E. Maragliano, Genoa, said in his address before the general conference that there existed in most individuals a natural immunity against tuberculosis. By this fact is explained the escape of the large number of persons who are daily exposed to infection. This power of resistance is apparently potent in direct ratio to the standard of good health maintained in the individual. Any decline of the vital strength renders the organism just so much more liable to invasion. The truth of this assertion is confirmed by experimentation on lower animals and by observation on the denizens of the tenement districts. The object for which the author had been zealously laboring for thirty years was the establishment of this standard of immunity through improved methods of living and also by the use of an immunizing serum that might be injected hypodermatically or perhaps taken by the mouth. Professor Maragliano thought he had made some progress in this direction, as his experiments on animals had met sufficient success to justify a trial on man.

Closing Session.

At the close of the general session addresses were delivered by representatives of the several nations that had taken part in the congress. It was regrettable that the committee representing the United States should have been refused admission to the stage at the inauguration of the ambassadors and that our delegate alone failed to deliver his address. In this connection and in explanation of the above-mentioned irregularities it should be stated that the preparations for the accommodation of the scientific and public meetings of the congress were very inadequate. The sections were forced to occupy widely separated halls, to which there were unsatisfactory means of transportation. Perhaps the most noticeable lack of organization was to be seen in the want of an authoritative bureau of information. Even the committees were unable to tell when or where many of the important proceedings would occur.

The social festivities, however, were abundant and enjoyable. Americans especially appreciated the hospitality of Mr. and Mrs. Arthur S. Hardy, the United States minister to Spain.

Prizes.

At the session held in 1897 at Moscow that city voted, in honor of the Russian meeting, a prize to be awarded for original research. This was unanimously awarded Professor Metschnikoff. A similar prize, donated by the city of Paris, was awarded, after a spirited contest, to Professor Grassi. On the first ballot the votes stood Grassi 42, Roentgen 39, and Lavaran 5.

The next place of meeting will be at Lisbon, Portugal, in 1906, with Professor Alfredo da Costa of that city as president.

(*To be continued.*)

ILLINOIS STATE MEDICAL SOCIETY.

Fifty-third Annual Meeting, held in Chicago, April 29 and 30, and May 1 and 2, 1903.

The society convened in Tremont Hall of Northwestern University, under the presidency of Dr. M. L. Harris, Chicago.

Addresses of welcome were delivered by Dr. Taylor, prosecuting attorney of Chicago; Hon. Henry G. Foreman, president of the county commissioners, and by Dr. James H. Stowell.

The response to these addresses was made by Dr. M. L. Harris, the president.

President's Address.

President Harris, in his address, stated, among other things, that success, as applied to the life of the physician, meant something else than his own opinion of himself. It meant the realization by others of the value of his labors, of their value, not simply from a commercial standpoint, but from the standpoint of the scientist and the humanitarian, to others of his knowledge and skill. That natural aptitude and ability count for something in determining the degree of success to which an individual may attain must be granted, as it is a common observation in all walks of life that some individuals with scarcely any opportunities in early life have struggled to the top, over almost insuperable obstacles; notwithstanding this fact, the scientific child study which so many are now vigorously prosecuting with such rich rewards for their labor, demonstrates clearly that much of the dulness, the apparent stupidity and lack of capacity to learn in the early years of life were closely related to, if not dependent on, certain physical defects, and that many of these defects and the capacity to learn had, in a broad sense, a nutritional basis.

He recapitulated briefly the factors which contribute most to the scientific success of the physician, namely: 1. A thorough knowledge of the rules of logic and the theory of reasoning, in order that the physician might be able to deduce warrantable conclusions from the evidence at hand. 2. The physician must train his powers of observation, in order to present to his reasoning faculties correct data. 3. He must be familiar with what is known on the subject before him, in order that he may correlate his own observations with the facts presented by others.

Approximately seventy papers were read before the three Sections, and three general addresses delivered. We present abstracts of some of the more interesting papers.

The Dangers of Exclusive Milk Diet in Nephritis.

Dr. A. C. Croftan of Chicago read a paper with this title. The popular prejudice in favor of an exclusive milk diet in nephritis, and the fundamental fallacies of this prejudice, were pointed out. The three indications for dietetic treatment of nephritis were: 1. Protection of the secreting epithelium of the kidney. 2. Protection of the cardio-vascular apparatus. 3. Protection of the general nutrition of the patient. The author presented reasons why an exclusive milk diet met none of these requirements. The best substitute for an exclusive milk diet, as deducted from modern investigations into the causes of nephritis and the excretion of urinary solids in inflammatory diseases of the kidneys, was pointed out.

The Breast Versus the Bottle in Infant Feeding.

Dr. Alfred C. Cotton, Chicago, compared the mortality statistics of natural and artificial feeding. He referred to the relative morbidity attending each method. Human milk was compared with that of other mammals. He pointed out the dangers of the acceptance of even the best known methods of artificial feeding. The more nearly perfect the food laboratory the greater were the possibilities of harm from over-confidence in artificial methods. Infants were too frequently denied the breast for trivial and insufficient reasons. In view of our knowledge of the morbidity and mortality of artificially fed infants what right had physicians needlessly to expose any infant to such chances? He made a plea for the establishment of a bureau of information and supervision, to facilitate the procuring of wet nurses when required.

Cockroaches as Typhoid Infection Carriers.

Dr. Rosa Engelmann, Chicago, discussed this subject under the following heads: 1. Vermin as active intermediary hosts of various infections. 2. History of a house epidemic of typhoid fever. 3. Cockroaches, sewage and water denizens not heretofore classed as typhoid infection carriers. 4. Need of examination and cultures from intestinal contents and from feet of cockroaches for pathogenic germs—especially the Eberth bacillus. 5. Opportunity the coming summer (after necessarily prolonged rainfall) for such work in the vermin-infested slums of Chicago. (A portion of this paper was reported in The Journal, Feb. 14, 1903, p. 464.)

Hysteria.

Dr. Hugh T. Patrick, Chicago, reported cases of hysterical paraplegia, hysterial amblyopia with rigid pupil, hysterical anorexia, hysterical pseudo-meningitis and hysterical deafmutism.

The Treatment of Some of the Degenerations of the Cerebro-Spinal Apparatus, with Particular Reference to Optic Atrophy.

Dr. Archibald Church, Chicago, said that the general feeling was that degenerations taking place in the conducting tracts of the cord, as in locomotor ataxia and atrophy of the optic nerve, arising from any cause, as well as the changes in the brain and cord that are found in paretic dementia, are quite unamenable to treatment. In all of these conditions the tendency to remission was, in itself, a confusing element in judging the therapeutic value of any line of treatment. In the case of the optic nerve, the ophthalmoscope enabled the physician to accurately see changes which were taking place, and by approximate tests variations for better or worse could be actively determined and systematically recorded. A number of cases of optic atrophy associated with a secondary syphilis had been under observation for from two to ten years, and were made the basis of an estimate of the value of mercury in controlling these degenerations. Ophthalmoscopic examinations and perimetric records made in these cases by competent oculists demonstrate that in some instances degenerations in the optic nerve could be distinctly controlled. Other cases of locomotor ataxia and paretic dementia were adduced, in which the clinical records indicated a similar retarding influence on the processes of degeneration in the brain and cord.

Euphthalmin as a Mydriatic for the General Practitioner.

Dr. Albert B. Hales, Chicago, said that the use of the ophthalmoscope was becoming more general in medical diagnosis. He pointed out the need of a drug to dilate the pupil, not only to study the condition of the fundus, but also to note the condition of the cornea, iris and lens. Atropin was too powerful, and destroyed accommodation. Homatropin was of only less strength, and was expensive. Cocain was good, but dangerous to the eye. Euphthalmin scarcely affected accommodation; it dilated the pupil fully and in a short time. It had no dangerous element about it, and its effect passed quickly away. He detailed experiments.

Abdominal Pain in Pleurisy and Pneumonia.

Dr. James B. Herrick, Chicago, said that pain in pleurisy and pneumonia might be referred not only to the affected side of the chest, but to the opposite side of the abdomen. In the latter case, abdominal disease, for example appendicitis, might be simulated. He dwelt on the importance of recognizing the thoracic organ of pain, as it might thus prevent surgical interference. Illustrative cases were reported. The anatomic basis for the referred pain was found chiefly in the course and distribution of the intercostal nerves. The diagnosis was generally easy when once the possibility of the thoracic cause for the abdominal pain was thought of, and a careful examination of the chest made.

Some Unusual Cases of Chorea.

Dr. L. Harrison Mettler, Chicago, reported cases and advanced the idea that chorea was a symptom and not a disease; that its etiology was not so obscure as it appeared to be; that it has some remarkable frequently overlooked features in its symptomatology, and that its treatment was varied and deserving of more careful study.

The General Practitioner and His Relation to Early Surgical Operations.

Dr. E. B. Montgomery, Quincy, called attention to the fact that the internists were too often apt to be influenced by the law opinion that surgical operations were only to be done as a last resort, and unconsciously lent themselves to delay in a large class of cases that should have surgical intervention early in their course. He contended that the unfavorable results which were shown to follow in too large a percentage of cases of carcinoma of the breast and uterus were due to late operation. Appreciating this, the general practitioner should encourage among his patrons immediate consultation of the physician concerning every trouble with the breast in women, however insignificant, or any irregular hemorrhage, occurring after the age of 40 years, and, if there was the slightest question concerning the presence of malignant disease, should associate a surgeon with him in the case. In the author's opinion, the same rules should obtain in typhoid fever, with any evidence of perforation; in appendicitis; in cholecystitis with enlargement of the gall bladder, and in enlargement of the prostate gland after the catheter life has begun; in pleuritic effusions lasting over two weeks, either purulent or not, and in hypertrophic cirrhosis of the liver, the early presence of the surgeon was advocated. In support of these opinions, facts and cases were adduced.

The Traction Injury of Arteries.

Dr. S. M. Wylie, Paxton, said that normal nutrition and vascularization of the extremities depended on an unobstructed flow of normal blood. Stagnation, partial or complete, favored the formation of fibrinous clots. Traction injuries of the arteries, by disturbing the normal relation and function of the various coats, favored the formation of thrombus in two ways: 1. The ruptured walls of the interna curling up in the lumen of the vessel act as an obstructant to the current. 2. The loss of contractile power from the overstretched or torn muscular fibers favored stagnation and arrested the flow. Both were factors in the function of occlusion thrombi, causing complete arrest of the circulation and subsequent death of the part. This was a surgical accident often overlooked at the time of the first dressing of an injured extremity, and when subsequent gangrene ensued, as it often did, it was attributed to faulty methods of applying the dressing.

Modern Surgery of Congenital Cleft Palate.

Dr. S. R. Hopkins, Springfield, gave a description of the uranoplastic operation in its infancy, and its advantages over later operations, with the statistics furnished by different operators. He likewise gave a description of staphylorrhaphy in later life; also made remarks on the power of speech following operations. He recommended a change from the usual *modus operandi* of closing continuous clefts in children over six months of age, with a report of two cases illustrating the proposed method.

The Treatment and the Causes of Death in Placenta Previa.

Dr. P. M. Burke, La Salle, pointed out that the cause of death in placenta previa was extensive rupture of the uterus and not hemorrhage due to a mere separation of the placenta in the act of turning, as was popularly believed. Out of 9 cases, in all of which he turned, there were 4 extensive ruptures. Three of the patients died and one recovered. The cause of death applied to the mother, as the cause of death of the child was self-evident. The only deaths were in the ruptured cases unrepaired. The lack of knowledge was due to small individual experience, consequent on the infrequency of such cases. In numerous cases of turning, in about a thousand cases of obstetrics, he never had had a rupture except in placenta previa. The occurrence of rupture in these cases was not a coincidence, but due to the friable, brittle condition of the lower segment of the uterus. The treatment was surgical operation, prompt, heroic and successful repair of the rupture.

Tuberculosis of the Vestibule of the Female Genitals.

Dr. J. H. Stealy, Freeport, reviewed the literature and referred to the rarity of the lesion; the possible cause of the unfavorable course taken by the disease in this region; the difficulties attending the determination of whether the lesion was primary or secondary, and its bearing on the prognosis. He said the tuberculin test was the only accurate method.

Officers for the Ensuing Year.

The following officers were elected: President, Dr. Carl E. Black, Jacksonville; secretary, Dr. E. W. Weis, Ottawa; treasurer, Dr. Everett J. Brown, Decatur. Bloomington was selected as the place for holding the next annual meeting.

The new constitution, in conformity with the plan of the American Medical Association, was adopted without material change.

Marriages.

Horace M. Simmons, M.D., to Miss Caroline F. Johnson, both of Baltimore, April 22.

Edwin H. Ehlert, M.D., to Miss Elizabeth S. Pike, both of Hartford, Wis., April 25.

Maynard A. Austin, M.D., to Miss Anna Grace Baker, both of Anderson, Ind., April 29.

S. Edward Sanderson, M.D., to Miss Clara May Stevens, both of Detroit, Mich., April 28.

Augustin V. Wendell, M.D., to Miss Catherine F. Klein, both of Newark, N. J., March 25.

Thomas C. Peebles, M.D., to Miss Maud Van Tine, both of Lutherville, Baltimore County, Md., April 23.

Deaths.

James Bonaparte Greeley, M.D. Vermont Medical College, Woodstock, 1855, died at his home in Thornton's Ferry, N. H., April 21, from heart disease, after an illness of two days, aged 71. He was born in Nashua, N. H., served as surgeon of the First Rhode Island Regiment in the Civil War, and was one of the best-known physicians in Southern New Hampshire. He also represented the town of Merrimack in the state legislature.

Washington Franklin Anderson, M.D. University of Maryland, Baltimore, 1841, the oldest physician in Utah; once medical adviser to Brigham Young, a resident of Salt Lake City for forty-six years; first president of the Utah Medical Society; a member of the territorial legislature in 1860 and 1861, died at his home in Salt Lake City, April 22, after a short illness, aged 80.

Herman H. Schaberg, M.D. Detroit College of Medicine, 1878, a member of the American Medical Association, and the Kalamazoo Academy of Medicine, at various times health officer and city physician of Kalamazoo, died at his home, April 24, from pneumonia, after an illness of one week, aged 54.

Hiram Long, M.D. New York Medical College, New York City, 1859, surgeon in the Civil War, for several terms president of the Sunbury (Pa.) Medical Association, died at his home in Sunbury, from heart disease, April 24, after a short illness, aged 71.

Benjamin Morris, M.D. University of Virginia, Charlottesville, Va., formerly of Martinsville, Va., died at the home of his father, Dr. William W. Morris, near Rangeley, Va., from consumption, April 15.

William H. Wooden, M.D. Medical College of Ohio, Cincinnati, 1879, a member of the Decatur County (Ind.) Medical Society, died at his home in Greensburg, April 23, aged 45.

Addison Cyrus Hinkson, M.D. College of Physicians and Surgeons of San Francisco, 1901, of Nevada City, Cal., died suddenly in San Francisco, April 22, from heart disease, aged 28.

William R. Davis, M.D. Eclectic Medical College of the City of New York, 1891, died at his home in Utica, N. Y., from consumption, April 19, after a lingering illness, aged 47.

Joseph A. Stegmann, M.D. Hahnemann Medical College, Philadelphia, 1886, died at his home in Philadelphia, April 24, from typhoid fever, after an illness of two weeks, aged 40.

Thomas A. Pineo, M.D. Long Island College Hospital, Brooklyn, 1898, died at his home in Brooklyn, April 19, from pneumonia, after an illness of nine days, aged 38.

James R. Todd, M.D. Kansas City Medical College, 1883, died at his home in Gridley, Cal., April 21, from septicemia, following an accident, after a long illness, aged 59.

H. T. Breckbill, M.D. Pulte Medical College, Cincinnati, 1878, died suddenly while walking from his office to his house in Columbus Grove, Ohio, April 22, aged 60.

Roswell E. James, M.D., died at his home in Kalamazoo, Mich., April 23, from internal hemorrhage, after an illness of two days, aged 68.

Richard R. Breisch, M.D. Jefferson Medical College, Philadelphia, 1881, retired from practice, died at his home in Ringtown, Pa., April 22.

Charles E. Reese, M.D. Jefferson Medical College, Philadelphia, 1855, died at his home in Lowndesboro, Ala., April 25, after a short illness.

William W. Miller, M.D. Western Pennsylvania Medical College, Pittsburg, died at his residence in that city, April 16, from pneumonia.

Edwin B. Reed, M.D. University of Pennsylvania, Philadelphia, died at Little Togus, Me., April 24, from dropsy, aged 65.

D. J. Grandstaff, M.D. Louisville Medical College, 1878, died at his home in Mason, Texas, from exposure, April 22.

Jared M. Newell, M.D. University of Buffalo, 1873, died at his home in Rochester, N. Y., April 23, aged 82.

Robert M. Morgan, M.D., died at his home in Decherd, Tenn., April 25, from heart disease, aged 70.

State Boards of Registration.

Rhode Island Report.—Dr. Gardner T. Swarts, secretary of the Rhode Island State Board of Health, reports the examination held at Providence, April 2 and 3, 1903, as follows: Number of subjects examined, 7; total questions, 70; percentage required to pass, 75; written examination; total examined, 14; passed, 9; failed, 5.

Association News.

New Members.

New members for the month of April, 1903:

ALABAMA.

Ellis, J. L., Dothan.
Parker, E. C., Montgomery.
Mertins, Paul S., Montgomery.
Henderson, W. T., Mobile.
Lull, Cabot, Birmingham.
Jenkins, J. F., Coleanor.
Campbell, Douglas G., Mobile.
Kennedy, J. O., Kennedy.
Parke, T. D., Birmingham.
Atkins, Jas. M., Troy.
Arnold, L. W., Florence.

ARKANSAS.

Dickson, H. N., Jamestown.
Stewart, W. S., White Oak.
Morrow, F. R., Green Forest.

CALIFORNIA.

Farrow, E. J., San Francisco.
Eaton, G. L., San Francisco.
Steinwand, O. W.; Selma.
Cumming, H. F., Angel Island.
Van Dyke, E. C., San Francisco.
Jones, L. F., Tuolemne.

COLORADO

Spaulding, W. F, Greeley.
Espey, J G, Trinidad.
Robinson, G. W, Trinidad.
Blackman, A A, Colorado Sprgs.

CONNECTICUT.

Miller, G R, Hartford
Anderson, H G, Waterbury.
Murphy, W. G., East Hartford.

DISTRICT OF COLUMBIA.

Perry, G N, Washington.
Prentiss, D. W, Washington

FLORIDA.

Fernandez, J. D, Jacksonville.

GEORGIA.

Thornton, H E, Hartwell.
Sikes, J. A. B., Iron City.
Wright, T R, Augusta
Corry, J A, Barnesville
Kenyon, O T, Dawson
Moore, N. McH., Augusta.
Dean, R H, Jacksonville

IDAHO

Bibby, S E, Grangeville.
Allen, O J, Custer.

ILLINOIS

Neale, R A, Chicago
Eberhart, N M, Chicago.
Mastin, J G, Chicago
Ryerson, E W, Chicago
Pirosh, Berthold, Chicago.
Rice, May C, Chicago
Hecht, D'Orsay, Chicago
St Clair, F P, Chicago
Williams W C, Chicago.
Wright S E, Chicago
McEwen, E L, Chicago
Snyder, K F, Freeport
Kercher, W L, Freeport
Wilson, W. H., Kankakee.
Hagler, A Lee, Springfield
Horner, Clyde F, El Paso

INDIANA.

Cannon, G H, New Albany.
Weathers, J F, New Albany.
Potter, Theo, Indianapolis.
Bailey, G D, Spiceland
Lynch, J Y, Rosedale

IOWA

Fisher, E E, Rodney
Burge, A J., Iowa City
Spearman, F. S, Hawkeye
Martin, D T, Pomeroy
Frank, C. S, Epworth
Castello, W E, Zwingle.

KANSAS.

Barnett, B M, Rosedale
Smith, A. J Leavenworth
Alkire, H L, Topeka
Fear, J C, Waverly.

KENTUCKY

Daugherty, C G, Paris
Bruner, B L, Hardyville
Yazell W S, Maysville
Manning H R, Louisville
Bohannon, J G, Greenville
Moren, J J Louisville
McClure, W B, Lexington.
Cartwright, F D, Bowling Green
Mason, H M, Hazel
Robins, Vernon, Louisville
Jenkins, G B, Louisville
Moneyhon, T J, Augusta
Abell, Irvin, Louisville
Phythian, J L, Newport

LOUISIANA.

Butterworth, W. M, N Orleans
Campbell, R C, Shreveport
Holt, Jos, New Orleans
McIlhanny, P A, New Orleans
Brosnan, D S, New Orleans
Calhoun, W. W, New Orleans
Pray, A A, New Orleans
Pothier, O L, New Orleans.

Miscellany.

The Formula of Disease.—An exchange quotes the formula of disease as

$$D = \frac{M V N}{R}$$

D represents the disease; M the microbe, multiplied by V, its virulence, and N its numbers; divided by R, the resisting powers of the organism. We would suggest, as an improvement, to multiply the resisting powers of the organism by P, the wise guidance of the physician, which immeasurably reduces the quotient of the disease as expressed in the first formula. The laity have the impression that the physician alone fights the disease. They seldom or never realize that the ablest physician can work only through the resisting powers of the organism, and if these are defective he is baffled at every turn and all his efforts are fruitless; he can not save the patient any more than the pilot can save the vessel if it is leaking too badly. The pilot takes the helm and steers the ship past the shoals and rocks by the shortest route to the dock, inspiring and aiding the officers and crew to do their utmost to keep it afloat a little longer, but if the ship is too badly scuttled it will sink before reaching the dock, in spite of all his knowledge and skill. If the public once realized that the same is true of the physician, they would cease to expect the impossible of him, and the platform on which charlatans and Eddyites build would be cut from under them with the general recognition of the truth in the amended formula:

$$D = \frac{M V N}{R + P}$$

Phototherapy in Neurasthenia.—Joire has found that red light has a marked beneficial action in neurasthenia. It soothes the nerves; increases the vitality and appetite; improves digestion, and the nutrition in general seems to appreciate the benefit He has been applying it for this purpose on a large scale during the past year, and lauds it highly in his communication on the subject to the "Nord Méd," ix, No. 181.

THE NEW ORLEANS SESSION

RECORD-BREAKING ATTENDANCE.

New Orleans Session Attended by Large Delegations from All Parts of the Country.

The fifty-fourth annual session of the American Medical Association at New Orleans has proven a great success in point of attendance and in scientific interest. Reports by telegraph received as we go to press predict that this will be the largest session ever held. At the close of the registration department Wednesday night, 1,941 members had registered. This was at the close of the second day, and, although most of those present at the annual sessions register before the end of the second day, there are always a number who register later. It is, therefore, probable that the New Orleans session will be the largest ever held. It will be remembered that at the Atlantic City session in 1900 there was a total registration of 2,019, at St. Paul 1,806 and at Saratoga 1,425. The New Orleans session needs only 79 more registrations in order to break the record. All parts of the United States are represented.

ARRANGEMENTS SATISFACTORY.

Chief Hotels Crowded but Ample Accommodation Elsewhere. Weather is Fine.

It was feared last week that the temperature might interfere with the pleasure of those in attendance, but this fear has not been realized, for the weather is delightful and no complaint is heard in this regard.

The Committee of Arrangements, whose efficient chairman is Dr. Isadore Dyer, are being praised for the excellent way in which their work has been done, and while there is some crowding in the leading hotels, ample accommodations have been provided for all the visitors.

HOUSE OF DELEGATES MEETS.

Busy Meetings Held Daily—The Reports of Trustees and Officers Read.

The House of Delegates met in preliminary informal session Monday afternoon and evening and transacted considerable business. The meetings of Tuesday and Wednesday have been very busy ones and a large amount of business has been transacted.

Labor on the Code of Ethics.

The question of the Code of Ethics and its revision was met by referring the matter to a committee composed of one representative from each state represented in the House of Delegates, together with the original special Committee on Revision of the Code of Ethics. This enlarged committee held several meetings and carefully and thoroughly considered the matter.

EXCELLENT SCIENTIFIC PROGRAM.

Sections Have Large Attendance and Much Interest Is Shown.

The scientific part of the convention is very well organized, and almost all of the sections started out with prospects of valuable series of meetings. The attendance at the section meetings is unusually good and excellent work is being done.

The publication of the scientific proceedings of the New Orleans session begins in this issue with the address of the President, Dr. Frank Billings, on "Medical Education in the United States." This was delivered at the first general meeting, in Tulane Theater, Tuesday, May 5, at 11 a. m. The same day, at 7:30 p. m., Dr. A. F. Jonas, Omaha, delivered the annual Oration on Surgery, taking as his subject "Cancer and Immunity." This oration appears in full in this issue.

Wednesday evening, at 7:30, Dr. J. M. Anders, Philadelphia, gave the Oration on Medicine. This also appears in full in this issue, the subject being "Social Conditions in America in Their Relation to Medical Progress and Disease."

SECTION PAPERS READ.

The Great Problems of the Art of Healing Are Discussed.

The good work done by the officers of the various sections in preparing their programs has been followed up by the co-operation of those listed to read papers. The publication of the papers read in the sections will commence in The Journal, May 16, and will be pushed rapidly. Some of the papers read in the Section on Surgery and Anatomy, the Section on Cutaneous Medicine and Surgery and the Section on the Diseases of Children will be printed in full in next week's issue.

Section on Hygiene and Sanitary Science.

The important subject of "Vital Statistics" was the subject of a spirited discussion in the Section on Hygiene and Sanitary Science. Dr. H. M. Bracken, chairman of the section, in his address in opening the program, emphasized the need of uniformity in this regard, and he was followed by Dr. Cressy L. Wilbur of Lansing, Mich., who urged co-operation in vital statistics' gathering. Dr. Wilbur said that those who use vital statistics most ought naturally to be the ones who should say what is wanted in those statistics and how they should be arranged to be of the most service. Then, when it is known just what is wanted, the general practitioner should be educated to exactness in reporting deaths, for it is he who reports the most of the deaths.

The section agreed on the importance of this endeavor to secure uniformity of registration of vital statistics and general agreement in methods and passed a resolution endorsing this plan. The exact wording of the resolution is not given in our telegraphic report. It will be given in a later issue.

Section on Surgery and Anatomy.

Dr. James E. Moore, Minneapolis, chairman of the Section on Surgery and Anatomy, chose to present as the theme of his address before that section, "A Plea for Exploratory Operations." He urged that modern aseptic methods in the hands of experienced surgeons made an opening into the body justifiable for the sole purpose of determining just what condition was present. He made the plea with carefulness, lest he should give any encouragement to those who "rush in where angels fear to tread," and laid emphasis on the fact that most exploratory operations should be done only by the able surgeon, who is fully competent to know indications, to recognize conditions found and to immediately repair anything needing attention.

Prof. Adolph Lorenz was one of the distinguished foreigners present at the meetings of this section. He was introduced to the audience and made a few remarks.

Section on Diseases of Children.

Dr. John C. Cook, chairman of the Section on Diseases of Children, had copies of a little pamphlet for distribution to the members of that section in connection with his chairman's address, which was on the development and care of children. This pamphlet was a catalogue of the various articles on pediatric subjects that have appeared in American and foreign medical publications during the past year.

PHYSICIAN ON CANAL COMMISSION.

President Roosevelt Asked to See that Health Matters at the Isthmian Canal are thus Supervised.

A resolution was unanimously adopted Wednesday urging the President to name a reputable medical man on the Isthmian Canal Commission in order to insure energetic sanitary control and thereby avoid repetition of the enormous loss of life from preventable disease.

VIVISECTION.

Association Praises Work of Legislation Committee and Makes Memorial to Congress on the Subject.

The action of the Committee on Legislation in securing the defeat of the anti-vivisection bill in Congress was indorsed, and a resolution was adopted memorializing Congress to give no further attention to the subject.

OTHER NEW ORLEANS MEETINGS.

Association of American Medical Colleges Meets and Raises Medical College Standard.

At the annual meeting in New Orleans, May 4, the report of the committee on requirements for admission to medical colleges was adopted, after amendment, by the Association of American Medical Colleges. It now requires four full years of work in the high school or its equivalent for eligibility to admission in a medical college.

The American Association of Medical Editors was also in session, and elected Dr. Sajous of Philadelphia president.

The Southern Medical College Association, also meeting at New Orleans, re-elected Dr. Christopher Tompkins of Richmond president. It will meet in Birmingham, Ala., next year.

FULL REPORT OF THE SESSION.

Minutes to Appear Next Week—Proceedings of House of Delegates.

As stated above, the publication of section papers will begin in THE JOURNAL next week. No attempt is made to give an account of the session in this issue, owing to the fact that THE JOURNAL goes to press on Wednesday. It is felt that the readers will appreciate receiving their copies at the usual time this week instead of waiting for an issue delayed for further telegraphic reports. Next week's issue will contain a full account of the New Orleans session.

The Board of Trustees and the Committee on Prophylaxis of Venereal Diseases made their reports to the House of Delegates. These appear in full below.

Revised Code Adopted—Atlantic City Next Session.

By telegram Thursday afternoon: The revised Code was unanimously adopted amid great enthusiasm. Atlantic City was selected as the meeting place for 1904.

Report of the Board of Trustees of the American Medical Association for the Year 1902.

To the Officers, Members and House of Delegates of the American Medical Association:

Your Board of Trustees, in complying with the requirements of your Constitution and By-Laws, beg leave to submit the following as our annual report.

Last year we presented you as Exhibit "A" the Auditor's "Balance Sheet" made from the books of the Association, including those of THE JOURNAL office, and of your Treasurer. This year, as Exhibit "A," we give you the cash receipts and expenditures taken from the monthly reports of THE JOURNAL office; Exhibit "B," your Treasurer's report, and to our report we append as Exhibit "C" the Auditor's "Balance Sheet."

RECEIPTS.

1902.	Journal Office.	Dr.
Jan. 1—Cash on hand		$ 522.10
Dec. 31—Cash from:

		$103,040.13

SUMMARY.

Dec. 31, 1902—		
Bal. cash in hands of Treas	$ 5,887.53	
Bal. cash in hands, Journal office.	535.01	
Chicago City School Bonds, par value $14,000.00, worth	15,168.13	
Amount invested in real estate	74,546.96	
Inventory acct. shown by auditors	35,683.53	$131,821.16
Dec. 31, 1901—		
Assets as shown by auditors	$87,839.91	
Dec. 31, 1902—		
Miscellaneous account payable	3,840.69	
Balance net profit, 1902	40,140.56	$131,821.16

A comparison of this summary with the statement made at the Denver meeting will show the great growth made financially by the Association in the short period of five (5) years.

At Denver your Treasurer reported total cash received from members for the year, $32,200.00.

Receipts for 1902 from same sources, $59,180.00, showing a gain of $26,980.00, indicating but little short of twice as many members.

The total amount of cash in your Treasurer's hands was $17,092.85, which included the then reserve for building purposes of $3,000.

The tables above show cash, etc., on hand, $21,590.67, being a gain in cash of $4,497.82, and a building on which we have spent $74,546.96, a gain of 71,546.96 over the reserve funds.

Our total Journal business, including cash in hand, as shown by the report of the Trustees for 1898, was $47,140.07.

This year the books of The Journal office show in cash $130,021.30, which amount includes $9,000 less in requisitions, but, not considering that, the face of the books show a gain of $82,891.23 in business over 1898, the gain being almost double the total business reported that year.

Last year (1902) report for year 1901 showed net assets $87,839.91.

This year, deducting balance due on property, our net assets are as follows:

Real estate, etc	$ 74,546.96
Furniture and fixtures	2,351.70
Machinery	17,174.40
Chicago City School Bonds	15,168.13
Inventories, paper, ink, etc	2,407.67
Bills receivable	901.67
Accounts receivable (earned)	12,848.09
Cash on hand and in bank	6,422.54
Total, 1903 report, for year 1902	$131,821.16
Excess over 1902 report	$ 43,981.25
Less miscellaneous account payable	3,840.69
Net profit	$ 40,140.56

REAL ESTATE.

EXHIBIT "C."

Jan. 27, 1903.

E. Fletcher Ingals, Esq., American Medical Association, Chicago.

Dear Sir:—In accordance with your instructions, we have examined the books of The Journal of the above Association and such records as were available in the office of its Treasurer, and we beg to hand you herewith statements of: Assets and liabilities as at Dec. 31, 1902; profit and loss account for the year ending Dec. 31, 1902.

We have examined vouchers or other evidence for all cash disbursements and have verified the cash in bank as shown by the above statements with statements furnished by the banks.

We found the books of The Journal to be neatly and accurately kept.

Yours faithfully,
The Investors' Audit Company.
(Signed) E. M. Mills, Manager.

AMERICAN MEDICAL ASSOCIATION.

Balance Sheet, Dec. 31. 1902.

ASSETS.

Profit on sale of government bonds	262.50	
Inventories of paper, ink, type and metal, Dec. 31, 1902	2,253.62	$177,759.79

COMPARISONS.

A comparison of the tables presented from the monthly report, "A" and "B," with the Auditor's report, shows apparent but not real differences, which have arisen from the system of bookkeeping which has been in vogue up to this time, but will not appear in the future. It will be sufficient to note a few points.

On the last page of the Auditor's report, "membership dues" is given as $55,455, while in Exhibit "B" it is given as $55,805. This arises from the fact that the Treasurer charges himself with $350, which he afterwards turned over to THE JOURNAL office as subscriptions, and when this $350 is deducted it leaves "membership fees" as given in Auditor's report. Again, on the same page of Auditor's report you note subscriptions $30,863.65, while in Exhibit "A" this same item is given as $41,570.48, but this amount includes an item of $10,706.83 collected by THE JOURNAL office, and afterwards passed to "membership dues," and when it is deducted we find the balance as shown by Auditor's report, $30,863.65, but it was necessary to enter, as shown *in Exhibit "A," to keep entries correct, and* you find in the credit side of "A" the amount, $10,706.83. You find on the same sheet of the Auditor's report "advertisements" $76,046.83, whilst Exhibit "A" shows only $69,340.55, the difference between the two, $6,706.28, being the amount earned on contracts not expired, and, hence, not collected at that time. Other items differ because of different combinations, but the result, as shown by the net profit, is the same.

The changes made in bookkeeping, by which all collections will be made through THE JOURNAL office, except interest on investments, will prevent all the difference to which reference has been made, except when the Auditor's report combines items differently from the way in which they are presented in our monthly reports. The change thus made will result in your Treasurer being the custodian of your surplus funds, and also of all invested funds, and the interest arising therefrom, and not a collector of anything. This consolidation of work and change in bookkeeping will save to the Association clerks' wages in the Treasurer's office.

AMERICAN MEDICAL ASSOCIATION.

Comparative statement for the years from 1895 to 1902 (inclusive):

1895—Membership fees for the year	$19,760	
Registration fees at Baltimore meeting	4,610	$23,370
1896—Membership fees for the year	$23,130	
Registration fees at Atlanta meeting	2,945	$26,075
1897—Membership fees for the year	$24,620	
Registration fees at Philadelphia meeting	7,580	$32,200
1898—Membership fees for the year	$28,945	
Registration fees at Denver meeting	4,815	$33,760
1899—Membership fees for the year	$32,840	
Registration fees at Columbus meeting	6,125	$38,965
1900—Membership fees for the year	$40,550	
Registration fees at Atlantic City meeting	6,150	$46,700
1901—Membership fees for the year	$46,505	
Registration fees at St. Paul meeting	5,050	$51,555
1902—Membership fees for the year	$55,805	
Registration fees at Saratoga meeting	3,375	$59,180

Dec. 31, 1901—Number of members	11,121		
Dec. 31, 1902—Number of members	12,540		1,419
Dec. 31, 1901—New members during the year	1,722		
New members at St. Paul	232	1,954	
Dec. 31, 1902—New members during the year	1,962		
New members at Saratoga	109	2,071	117
Dec. 31, 1901—Number of discontinuances for the year	674		
Dec. 31, 1902—Number of discontinuances for the year	547		127
Number of three-year delinquents Jan. 1, 1902			169
Number of three-year delinquents Jan. 1, 1903			159
Number of two-year delinquents Jan. 1, 1902			322
Number of two-year delinquents Jan. 1, 1903			298
Number of one-year delinquents Jan. 1, 1902			1,293
Number of one-year delinquents Jan. 1, 1903			1,513
Dec. 31, 1901—Membership fees paid during year	$51,555		
Dec. 31, 1902—Membership fees paid during year	58,800		$7,245
Cash collected during January, 1902	$17,625		
Cash collected during January, 1903	21,485		$3,860

ADVERTISING.

The amount actually earned from avertising during the year was $76,046.83, an increase of $13,813.47 over 1901.

Table 1, enclosed, shows comparative statement of the increase in advertising, cash collections, for the past five years, which indicates a gain of $9,898.73 for 1902 over 1901. The table represents actual collections, and is given only for a comparative basis.

During 1902 THE JOURNAL carried 3,046 advertising pages; of these 199 were for officers of the Association, the Contents and Digest, Journal, Association, State and National Society Announcements, Application Blanks, etc.

Advertisements to the amount of at least $8,000 have either been refused or dropped as being unacceptable to THE JOURNAL'S pages. We call attention to this fact to show that we are endeavoring to keep our advertising pages as clean as possible.

ADVERTISING DEPARTMENT.

The following comparative statement indicates the increase in advertising collections during the past four years:

	1898.	1899.	1900.	1901.	1902.
Jan.	$2,061.98	$3,292.84	$4,581.42	$5,998.63	$6,967.05
Feb.	2,415.67	2,391.65	3,133.42	4,829.22	4,617.17
March	1,557.51	2,763.23	2,701.08	3,657.68	4,936.53
April	2,603.23	2,595.11	4,431.01	5,620.98	6,842.31
May	1,095.43	3,240.89	3,238.98	4,915.41	5,522.46
June	1,568.44	2,343.75	2,665.99	3,715.91	5,341.44
July	2,689.05	3,453.41	3,764.67	6,683.78	7,580.32
Aug.	1,187.84	2,698.22	3,175.84	3,505.33	4,167.41
Sept.	1,635.44	2,093.68	2,953.72	3,923.05	4,501.35

	12,553	12,378	24,931	3,177	148

The figures given below indicate the count of the mailing list Jan. 1, 1903, compared with that of Jan. 1, 1902:

	Jan. 1, 1902.	Jan. 1, 1903.
Copies to members	11,107	12,553
Copies to subscribers	10,795	12,378
Copies to advertisers	272	332
Copies to exchanges (domestic)	140	150
Copies to exchanges (foreign)	47	64
Copies to medical colleges and libraries	117	114
Copies to subscription agents	72	81
	22,550	25,672

Indicating an increase for the year 1902 over 1901 of 3,122.

The following is a comparative statement of the net subscription collections for the years 1898, 1899, 1900, 1901 and 1902:

	1898.	1899.	1900.	1901.	1902.
Jan.	$576.31	$1,094.46	$3,614.08	$4,911.89	$7,575.03
Feb.	605.61	525.25	1,167.24	1,991.31	2,308.44
March	502.55	952.76	1,388.89	1,996.65	1,954.52
April	419.90	741.27	1,719.06	3,122.78	4,660.65
May	389.32	669.93	1,585.90	2,062.42	2,230.02
June	442.00	733.05	1,334.75	1,431.93	2,250.85
July	964.90	1,851.73	3,456.32	6,011.47	6,077.21
Aug.	638.18	1,208.38	1,246.03	1,974.59	2,337.87
Sept.	546.91	798.36	1,273.91	1,707.95	1,995.61
Oct.	623.33	1,313.20	3,285.49	4,152.10	4,355.48
Nov.	434.64	920.71	1,784.12	2,270.10	2,953.37
Dec.	602.90	1,474.42	1,872.14	2,160.26	2,871.43
	$6,746.55	$12,283.52	$23,697.03	$33,793.45	$41,570.48

Indicating a gain for 1899 over 1898 of	$ 5,536.97
Indicating a gain for 1900 over 1899 of	11,408.51
Indicating a gain for 1901 over 1900 of	10,096.42
Indicating a gain for 1902 over 1901 of	7,777.03

In this connection we beg to call attention again to two items in the Auditor's report: (1) Membership dues is given as $55,455; (2) subscription is given as $30,863. It is only fair that we should say that of this $55,455 The Journal collected and transferred $10,706.83. Of this amount $2,364.93 was for old members; $3,105 was for new members, which had been obtained through our traveling men, by circular letters, etc., and $5,236.90 was *for subscribers* that were transferred to the membership list. In other words, The Journal office should be credited with $8,341.90 more than the amount given by the Auditor's report, as this amount was paid to the Treasurer for new members *obtained through* work done in The Journal office.

As mentioned last year, our subscription account is practically a clearing-house for membership. Subscribers are urged to become members as fast as possible. With each receipt for subscription a letter is enclosed by the Editor suggesting that the subscriber join the Association. This accounts for the difference in the percentage of collections from subscribers and *members.*

As shown above, last year there was transferred $10,706.83 to the Treasurer. In addition to the amount collected at The Journal office, quite a number of subscribers who became members during the year, paid direct to the Treasurer. For every name transmitted The Journal office handed the Treasurer $5, and there is quite an expense attached to these transfers, for which The Journal receives no credit, since The Journal had paid agent's commission for securing the orders, in addition to giving The Journal free for three months.

On Dec. 30, 1902, the Treasurer handed in a list of 158 names of those who were delinquent members for the years 1900, 1901 and 1902, to be dropped from the mailing list. Two letters, *one on January* 7th and another on the 17th, were sent to these members, urging those to whom they were addressed to retain their membership. To date we have collected from 47 of these delinquents the amount of $462.50. These have since been restored *to our* mailing list, and the amount turned over to the Treasurer, leaving still 111. On February 11 another letter was sent to these delinquents.

PAPER STOCK.

Following is the cost of paper stock for the past three years:

1900.	1901.	1902.
$25,598.00	$29,835.00	$35,675.06

This shows a gradual rise each year, but, as the price was the same, the rise is accounted for in the increased circulation.

The following table shows the total number of copies issued each year, total pages, and amount of paper stock used:

	Total No. Copies.	Pages.	Reams.	Lbs. of Paper.	Tons.
1898	597,282	4,756	3,395	321,525	157.0
1899	710,950	5,382	4,832	461,420	230.0
1900	907,200	6,087	6,747	607,230	303.5
1901	1,146,575	6,510	9,052	814,680	407.0
1902	1,316,695	6,522	10,430	938,700	469 1/3

As will be noticed, the increase, in round numbers, of 1902 over 1901 was 62 tons.

Our mailing lists of 25,672 names on Jan. 1, 1903, show that our Editor has given us a journal mailed to more than 25,000 persons. This was scarcely considered possible five (5) years ago, but it should now be regarded as a starting point, *a locus a quo,* to a bona fide circulation of 100,000. This can be attained in the next decade at furthest, if every member of the Association will do his duty. If the secretary or president of each county society in every state can be induced to regard it as one of his duties to lay before his organization the claims of The Journal as the organ of the whole profession of these United States, and impress on the members that it is not only their privilege but their duty, a duty owed the regular medical profession of our common country, to subscribe for and support it, new names will be added to the list of members, not by tens, but by hundreds. There should be an honest and earnest rivalry in the profession of the different states to show the greatest percentage of gain in subscribing for The Journal. To aid in carrying out this idea, your Board of Trustees, being impressed more, if possible, than ever before with the necessity of promptly pressing to a successful termination our plan of reorganization, secured the services of Dr. McCormack of Kentucky, who is to visit the different state societies and as many county medical societies as possible up to the May session of the Association, and present the matter clearly to them.

This action of the board was also necessitated by the fact that our Editor was being overworked and needed to be relieved of labors not belonging to his editorial department, that he had cheerfully done, up to the point where he could go no further, and yet the work could not be dropped. The Journal is worthy of the support of every member of the profession, be he a physician in our largest city or an humble practitioner in a most remote corner of some small county. Each one can find in its pages thoughts and suggestions adapted to his individual needs. The Journal is in no sense the organ of any specialty. Its pages are open to all, but contributions to be accepted must show thought, not mere book papers, which could be read more easily in the originals from which they have been culled.

PRESSROOM AND OFFICE FURNITURE AND FIXTURES.

There was spent under this head in 1902 $259.70, but for 1903 *still further expenses will have to be incurred in furnishing our* new building, but when once made, since they are placed where there will be no need of moving, they will last for years, and soon the expense under this head will be nominal.

PLANT.

The machinery account as presented by the Auditor foots up $17,174.40 (last year the inventory showed $16,808.25), after adding a folder costing $2,148.50 and a motor $122.50, total additions $2,271, showing a deduction of about 10 per cent. for depreciation from use.

This inventory does not include two (2) large new presses, costing about $9,000, and two (2) automatic feeders, costing $2,750, which have been bought and placed in the new building, but have not been accepted; nor several electric motors, costing $1,200, for the same reason Total new machinery bought, but not accepted Jan. 1, 1903, but to be paid for when accepted and working satisfactorily, $12,950. Your Board of Trustees ordered *the purchase of a new linotype machine. When this is installed* night work will not be needed in the office. During the past year it was frequently necessary to have one or more of the linotype machines run overtime and at night, adding materially to the expenses of The Journal. This can now be avoided.

PRESSROOM FURNITURE AND FIXTURES.

Many additional conveniences under this head have been added since The Journal moved into its permanent home. The report of last year referred to the fact that in its then quarters The Journal was much hampered for space in which to transact its business, as needed conveniences could not be added. In our new building all these conditions are changed, and gradually everything necessary to the economical running of a first-class plant is being installed. We do not deem it necessary to publish in this report an inventory of all our fixtures and furniture. Suffice it to say that, whereas the inventory presented at the Denver meeting occupied a space of fifteen (15) lines in the report, a full page would be needed for this. I would call attention to only one item. The Denver report showed three (3) Miehle presses and one (1) Gordon press. We now have two (2) double and three single Miehle presses, and one Gordon and one Universal press, more than double what we then had. The change is greater in every other portion of the office.

Besides these two large presses, we have three single, presses, so that in case of failure of either of the large presses, we could still get out The Journal without much crowding.

Hence, our press facilities are practically perfect and give us an opportunity to do much work that has heretofore been out of the question. Further, it will enable us to get out our reprints within a reasonable time, as well as the Transactions of the various Sections and other work.

OFFICE FURNITURE AND FIXTURES.

Additions have been made to this department also, but as they were made since Dec. 31, 1902, they do not belong in this report. The office is now up to date.

LIBRARY ROOM.

On the third floor the front room has been arranged for a library. In it will be found the latest books, etc., sent to The Journal for review, etc. It will be used as a reading and reception room, where members of the Association will always be welcomed by the Editor. In this room will be held the meeting of your Board of Trustees from year to year.

The whole building is a credit to any organization, and the arrangement of the building in its relations to the balance of the property is such that it can be added to at any time that there should arise any demand for more space.

RESIDENCE PROPERTY.

It must not be forgotten that we own, in addition to our Journal building, three (3) residences on ground sixty by eighty feet. These we rent for about $140 per month, yielding us an annual rental of about $1,600, which we hope to increase to $1,800, being about 4 per cent. on the original purchase money for the five lots and houses. Instead of being compelled to pay out about $5,000 for rent, as we would have had to do for room enough to carry on our Journal work, we not only pay out nothing, except for taxes and insurance, but we receive an income of at least $1,600 from our own rents, making a difference of $6,600 to offset the interest on our investment, $82,665.26. For one to have suggested five years ago the possibility of this consummation of our hopes and wants, he would have been considered a veritable Colonel Sellers, and yet the profession of regular medicine now has its home, a building of which none of us need be ashamed. But while we present to you this pleasant picture, we do not wish you to imagine the work is completed. Much yet remains to be done. The success of your Journal depends as much on the future as the past, probably more. You have simply laid a foundation sufficiently broad on which you can build a superstructure in a journal of which the whole medical profession can be proud.

To make it a success there must be, as in all other enterprises, money behind it to tide it over any emergency. A successful bank lays up a reserve fund of undivided profit. Manufacturing enterprises do the same; so, too, must the American Medical Association begin to lay up judiciously a sum of money for future use The minimum of this fund, in the estimation of your Board of Trustees, should be $100,000. Less than that will not do. Times of depression and stagnation in business must come. We appear to be floating now on a tidal wave of prosperity, but the ebb must just as surely be met. To do this as it becomes you, you must have this reserve fund. As a basis of this reserve fund, we have $14,000 in Chicago city school bonds, worth now a little over $15,000. We ordered the *local trustee, Dr. Ingals, to add to this sum, $6,000, so as to* make our investment $20,000. We would suggest that the Association be just as careful about its expenditures for the next five years as it has been in the past, and all will be well. A false step will blight what now appears to be the brilliant possibilities of your Journal. We do not mean that The Journal should not be improved. For that purpose money should be expended prudently, but freely. Your editor should be encouraged in every way to strive to keep The Journal to the forefront. More and better reading matter and less advertising matter about which any question could be raised should be a *sine qua non* in the conduct of your organ. Reference has already been made to the fact that advertisements have to be refused though the medicines presented in them are endorsed not by D.D.'s, but by M.D.'s who stand high. The manufacturers of proprietary preparations are fast learning that The Journal is living up to its rule of requiring the formula of every internal remedy advertised in its pages. The trend in regard to external remedies is in the same direction, though your board has not taken as decided and definite action in regard to them as we hope soon to do.

ACCOUNTS AND COLLECTIONS.

Several accounts for postage were presented during the year that has just passed, but as your board decided that the appropriation made at the Saratoga meeting could not be used to meet the expenses already incurred, none of them was paid, but the fund will be available for Section use at the New Orleans session. For these accounts to be promptly met, they must be presented to some member of the board by the third day of the New Orleans session, viz., May 7, 1903. If presented after that time they can not be properly audited and paid before the February meeting.

Your Board would report further that questions of the compensation of committees have been before us, but where there was no specific appropriation of money for their use, we have declined and will continue to decline to meet such requests. If the House of Delegates desires to expend money for committee work, as was done in the case of the Committee on Organization, we recommend that an appropriation not to exceed a definite sum be made, and then your Board of Trustees will have no trouble in adjusting all such claims. This has been your rule in reference to your Pathologic Exhibit, and we would ask that the same course be pursued in all such cases. For the reason that indefinite appropriations would have to be made (among many other as good or better reasons), your Board of Trustees would recommend that the exhibits at our annual meeting be left for the present at least under the control of the local committee, with a continuation of the restrictions already imposed, that no exhibit should be made of and for which advertisements would not be received for our Journal.

We feel that, whilst in many respects it would make the Association more independent in selecting a place for its annual session, yet it would appear undignified for us to be sending an agent to the place of meeting to arrange for halls of all kinds, and then to sell floor space to interested exhibitors, as would have to be done to save an enormous expense to the Association. All these things can be better done by the local profession, and we feel that, for the present, at least, the wisest course to pursue would be to keep in the beaten path, and go on as we have been doing till the Association has a sufficient reserve fund on hand with which to meet emergencies.

CODE OF ETHICS.

To avoid the possibility of an unnecessary expense, the Editor was directed not to print and send out, as he has done for several years, the "Code of Ethics" to medical students, in view of the fact that a special committee has under consideration a revision of the code, and are to report at our next annual meeting As changes may be made, we thought it would be better to await the action of the House of Delegates on the matter, and then have copies of the code printed and sent out.

NATIONAL INCORPORATION.

In regard to the question of a national incorporation, which would permit the American Medical Association to meet in any state or territory in the Union, to transact and complete its business without being compelled to hold an adjourned meeting in Illinois for the purpose of ratifying its acts done at the place of meeting, your Board of Trustees has considered it at much length. Much correspondence has passed and repassed between interested parties and various members of the board. All felt that if such an end could be attained, it certainly should be done. At our annual meeting the secretary of our board, Dr. Montgomery, arranged much of this correspondence, and presented it to us on the afternoon of the first day. The attorney, Mr. Baldwin, who had been advising with us, being present, by request, took part in the lengthy discussion of the question. At the end of the session, he was requested to take the correspondence, arrange and go over the same, and furnish an opinion which could be employed by the board as an explanation, should it decline to proceed in accordance with the requests made for them to act in this matter of national incorporation. We can arrive at no better way of presenting this matter so that it may be fully and clearly understood than by giving to the House of Delegates and, through you, to the whole Association, Mr. Baldwin's report verbatim. Whilst it is lengthy, it could not be well condensed without the omission of matters necessary to a clear comprehension of this mooted question. The sum and substance of this opinion is: (*a*) That the constitution and by-laws adopted at St. Paul had no binding force at all until they were readopted in Illinois; but the action had at Saratoga, and readopted in Chicago, is binding, and the charter and by-laws under which we are now acting are legal, since they were readopted in Illinois, where the Association is incorporated. (*b*) That a national incorporation such as is desired seems at present impossible. This communication constitutes Exhibit "D."

Respectfully submitted, E. E. MONTGOMERY, Secretary,
T. J. HAPPEL, Chairman, W. W. GRANT,
MILES F. PORTER, JOHN F. FULTON,
E. FLETCHER INGALS, H. L. E. JOHNSON,
W. S. RODMAN, A. L. WRIGHT, *Trustees.*

ADDENDUM: Your Board of Trustees would further report, that on March 31 the books of the Association showed your real estate account balanced—not a dollar being outstanding on any of our contracts. At that date we had on hand, including our Chicago City School Bonds, $39,427.23, but from this amount would have to be deducted unpaid bills for machinery not accepted at that time. We would recommend that the secretary of each Section of the American Medical Association be allowed the sum of $50 as compensation for services, postage, etc., annually, believing that this sum would enable the Sections to frequently retain an efficient secretary for a term of years. We would further recommend the following changes in the Association button: Leave the first "M" from the face of the button and make the bars plain, straight bars, instead of the present bars. We present you a model of this button and believe that it presents a neater appearance.

EXHIBIT "D."

LAW OFFICES, JESSE A. AND HENRY R BALDWIN,
CHICAGO, March 13, 1903.

To the President and Board of Trustees of the American Medical Association, care Dr. E. Fletcher Ingals, Chicago.

Gentlemen: On Friday, February 20, 1903, at your invitation, I attended a meeting of your board, held in this city, at which time there was discussed the propriety of certain of the by-laws of your Association, as well as the legality of their adoption, and the further, and perhaps more important question, whether or not your board ought to then proceed toward securing a national charter for the American Medical Association. You will remember that there were read at that meeting the following:

1. A letter from Dr. F. H. Wiggin to Dr. Simmons, dated November 18, 1902, raising the question whether the various changes made in the by-laws, at the meeting of the Association held in Saratoga, in 1902, and afterwards ratified at an adjourned session of that meeting, in Chicago, Illinois, were properly made, it being stated that such changes had not been proposed in conformity with the rules of the Association adopted at its meeting at St. Paul, June 5, 1901.

2. A letter from Dr. F. H. Wiggin to Dr. Johnson, as secretary of your Board of Trustees, dated November 19, 1902, raising substantially the same questions, and suggesting that the Association be incorporated "under the National Law."

3. A letter from Dr. F. H. Wiggin to Dr. Montgomery, dated December 8, 1902, criticising the method by which the changes in the by-laws had been made, quoting a portion of the law of the state of Illinois, and arguing that the changes which had been made in the articles of incorporation had not been made in conformity with the law of Illinois, and again suggesting that the Assocaition should "get a National incorporation rather than to continue its existence under the Illinois law."

4. Letter from Jesse A. Baldwin, Esq., to Dr. George H. Simmons, dated December 15, 1902, replying to objections made in the letters previously mentioned as to the method by which the changes had been made.

5. Communication dated December 22, 1902, from James Taylor Lewis, Esq., entitled "Opinion of the Counsel of the New York State Medical Association," addressed to Dr. Wiggin, criticising the conclusion reached in Mr. Baldwin's letter.

6. Letter from Jesse A. Baldwin, Esq., to Dr. Ingals, dated December 26, 1902, reporting that, at the request of Dr. Ingals, he had investigated to ascertain whether the American Medical Association could better accomplish its purposes by securing a National charter (if one could be secured), or by organizing under the laws of some other state or territory of the Union; and in which he advised, 1, that congress would have no power to create a National corporation for the purposes contemplated, by giving it a National charter; and 2, that, having communicated with the secretaries of state or attorneys-general of forty-seven states and territories, and having examined a large amount of printed and written matter, bearing on the corporation laws of the various states and territories, he was of the opinion that the proposed object sought to be accomplished, viz.: the right to hold its meetings, from time to time, and transact its business in any of the various states and territories of the Union, could not be secured by incorporating under the laws of any of the other states or territories. The letter further stated that while the laws of some of the states were more liberal in some of their provisions, with respect to corporations similar to our own, there were none in which the advantages offered were sufficiently superior to those granted by the laws of the state of Illinois, as to make them worthy of serious consideration; that in the letter from the Hon. Attorney General from Wisconsin, replying to my inquiry, he had said:

> I am very clear that the corporation could not be formed under our statutes, which would result in the general offices and the books and records being kept outside of the state. I also think it would be necessary to have the meetings for the transaction of business of the corporation, held in the state. Of course, this would not prevent other meetings being held for other purposes, in other states, but I think that the meetings of the stockholders and directors, for the transaction of business must be held here.

7. Extract from a letter from Dr. Simmons to Dr. Wiggin, dated Jan. 7, 1902, which does not relate to the subject matter, concerning which I was asked to advise

8. Letter from Dr. Wiggin to Dr. Montgomery, dated Jan. 9, 1903, in which Dr. Wiggin states that he sends with letter copies of opinions on the matter of the changes in the constitution or articles of incorporation of the American Medical Association at Saratoga; one being an argument sustaining their legality, from the counsel of the American Medical Association (myself), and the other questioning their legality, from the counsel of the New York State Medical Association (James T. Lewis, Esq.).

9. Copy of a letter signed by James T. Lewis, counsel, dated Jan. 16, 1903, addressed to Dr. Wiggin, president, New York State Medical Association, stating that there could be no possible question but that "the American Medical Association could be, and should be, incorporated under an act of congress," and, stating further, that "the case of McCulloch against the state of Maryland, 4 Wheat, 316, is the leading case and takes up and discusses the whole question and determines it finally" He further states that the "American Social Science Association" was thus incorporated, as also "The Jeanette M. Thurber Conservatory of Music," the charter for the former having been drawn up by Mr. Justice Simeon F. Baldwin, an able constitutional lawyer. The letter further says (referring to the opinion of your counsel, Jesse A. Baldwin, Esq., that congress has no power to incorporate the American Medical Association as a national organization, with rights to business anywhere in the United States), "The statement that it is impossible is absurd, I care not who makes such a statement." He further states that, in his judgment, there is but one course

to pursue, and that is to have the trustees of your Association forthwith apply to congress for a special charter, and have the Association "made a national body in fact," and further adds that he "would be glad to do it"

10 Letter from Dr Wiggin to Dr Montgomery, dated Jan. 21, 1903, evidently transmitting the previous letter to Dr. Montgomery

11 Letter from Dr. Wiggin, president New York State Medical Association, addressed to Dr. Montgomery, secretary of your Association, dated Jan. 31, 1903, in which he says that it seems clear to him that the alterations made in the articles of incorporation at the Saratoga meeting were improperly made (though the mistake was unintentional), because they had not 'been proposed in open meeting of the House of Delegates one year previous to being acted on," nor had they been "published at least three times in THE JOURNAL during the interim," etc, according to the provisions of the constitution or articles of incorporation adopted at the St Paul meeting, June 5, 1901, and quoting a part of the statutes of Illinois He suggests that the counsel for the American Medical Association (meaning myself) should not have taken advantage of the failure to file with the secretary of state of Illinois, as required by its laws, the constitution or articles of incorporation adopted at St Paul He also suggests that it would be wise for your board to secure a "national incorporation" rather than to continue its existence under the laws of Illinois, etc He says that "in case a national incorporation should be procured by a special act of congress, the House of Delegates could complete its business at its annual meeting, wherever it might be held" He further states that the only objection to this proposition which has been raised is that (raised by myself) the Association could not so incorporate, and he then refers to the McCulloch case, and mentions the incorporation of the American Social Science Association and the Jennette M. Thurber Conservatory of Music, and adds his endorsement to the deservedly high standing of Mr Justice Simeon F Baldwin, who drew up the "charter" for the American Social Science Association He expresses his belief that, whatever the expense and trouble incurred in procuring a national organization, it would be worth all it would cost "so to organize the American Medical Association that its interests may be carried on in future free from any disturbance from schemers and others who might seek their own, rather than the interests of the organization"

12 Letter from Dr. Wiggin to Dr Montgomery, dated Feb 10, 1903, offering to procure and send a copy of the charter of the American Social Science Association, and suggesting that Dr Montgomery look at the McCulloch case, 4 Wheat, 316, which Dr Wiggin says he is informed "discusses the whole question and determines it finally, and which your correspondent, the Hon O U Underwood, did not seem familiar with," and suggesting that Speaker Henderson be requested to look up the McCulloch case.

13. Letter from Dr. Wiggin to Dr. Montgomery, dated Feb 15, 1903, suggesting that your Board of Trustees appoint a committee to secure a national charter, with the help of Mr Lewis and one or two others

14 Letter from James Taylor Lewis, Esq, to Dr Montgomery, dated Feb 17, 1903, explaining why he can not send to Dr Montgomery a copy of the charter of the American Social Science Association, and adding that the attorney general has stated that he could not give any assurance that a charter could be secured during the then present congressional session, and suggesting extra effort on the part of the special committee of your board to procure this charter

15 Letter from Hon D B Henderson to Dr Montgomery, dated Feb 8, 1903, transmitting a letter from Hon O W. Underwood of Alabama, formerly a member of the House Judiciary Committee

16 Copy of a letter from Dr Montgomery to General Henderson, speaker, etc, dated Feb 4, 1903, stating that the American Medical Association is incorporated under the laws of Illinois, conducting a journal and owning property in Chicago, that a large part of its members is dissatisfied with the conditions which make it necessary that its transactions should be ratified by meetings held in Illinois in order to make them valid, and inquiring whether it would be possible to secure through congress a charter 'which would give us the privilege of holding our meeting in any state in the Union while still carrying on the business in Chicago I am told that the American Social Science Association has received a national charter through congress," and requesting Mr Henderson to inform him of the "method" by which he should proceed.

17. Letter from O W Underwood to Speaker Henderson, dated Feb 7, 1903, stating that Mr Henderson desired Mr. Underwood to write him "an opinion as to whether congress could properly grant such a charter" He then cites a paragraph from the opinion of Chief Justice Marshall, as follows.

> The power of creating a corporation, although appertaining to sovereignty, is not like the power of making war or levying taxes or of regulating commerce, a great substantive and independent power which can not be applied as incidently to other powers or used as a means of executing them It is never the end for which other powers are exercised but a means by which other objects are accomplished

The remainder of Mr Underwood's letter is as follows

> It is therefore clear that Congress may create corporations as a means of executing the other powers of government for instance, a bank for carrying on the fiscal operations of the United States or a railway corporation for the promotion of Interstate commerce, but unless the creation of the corporation is intended as a means of exercising, using or controlling some of the great powers dedicated to the federal government, there is clearly no authority for Congress to incorporate such a company
>
> From the statement contained in Mr Montgomery's letter I do not see wherein the incorporation of the company he proposes would come within the powers above mentioned and, therefore I do not believe that Congress would have power to incorporate this company Of course on the other hand, Congress has unlimited power to legislate for the District of Columbia, and would have power to incorporate a company for the purpose of doing business within the District of Columbia and incidentally it might transact its business throughout the United States as all other corporations do but such a charter would not be a general charter but would be local to the District and would have the same limitations on it that charters issued by the State Government have I return herein Mr Montgomery's letter

18 Letter from James Taylor Lewis, Esq, to Dr Montgomery, dated Feb 14, 1903, in which he states that he has read the opinion of Mr Underwood and the letters from Speaker Henderson, and that he can not see anything in either of them that goes to the point "except as an argument in favor of congress granting a charter to the American Medical Association" He adds:

> The Government has a Department of Education, and a Commissioner of Education, and it is along the lines of development in science and education that this corporation seeks federal recognition, and has a precedent granted in the charter granted the American Social Science Association, and the Jeanette M Thurber College of Music
>
> The learned remarks of Chief Justice Marshall are very apt in this connection because you are seeking a corporation which is to be the means of advancing and executing the educational branch of the Government, and this corporation should very properly receive recognition as a part of the educational system of the United States

He further adds that he is ready to be of any service in bringing about the securing of a charter, and is willing to present the matter to the attorney general or the president, and he adds, referring to the proposed charter, that "of course, it is a great concession by congress"

19 Letter from Dr. Lambert to Dr Montgomery, dated Feb 18, 1903, stating that Dr Wiggin and Mr Lewis had asked the writer to help obtain a national charter in case one should be applied for, and tendering his services.

20 Telegram from Dr Wiggin to Dr Happel, dated Feb 20, 1903, mentioning vol 30, U S Statutes at Large, page 804, as giving the charter of the American Social Science Association

After the foregoing communications had been read, I was called on to address the board with respect to the matters involved You will remember my statement made at that time, that the various modifications made in the articles of incorporation and by laws of the American Medical Association were advised in an honest effort on my part to utilize to the fullest degree possible the elaborate and (in the main) well devised and carefully worked out scheme of organization for the Association, and that I had advised only such changes as seemed to me necessary to make the organization legal under the laws of the state in which it had been incorporated long before I became its legal adviser; that at no time [illegible] there been any suggestion made to me by any person th[illegible] do more than this, that I confidently believed the obj[illegible] urged against the propriety of the legality of what h[illegible] done were based on a misapprehension of the situ[illegible] were due to a lack of accurate knowledge as to [illegible] the state of Illinois with respect to corpor[illegible] character

I am sure that the intimation of Dr Wigg[illegible] to Dr Montgomery, dated Jan 31, 1903 (No [illegible] the organization is in danger from sche[illegible] might seek their own rather than the inter[illegible] tion," is inadvertent, and can not be inte[illegible] insinuation that the able and honora[illegible] membership of the American Me[illegible] n[illegible]

The men who are, to the best of their ability, conducting the affairs of this Association, and endeavoring to make its existence and proceedings conform to the laws of the state of Illinois under which it is organized, are no more proper subjects of distrust and suspicion than would be the men prominent in the management of the New York State Medical Association, of which Dr. Wiggin is the honored president and James Taylor Lewis, Esq., the able counsel.

Assuming, as we are compelled to do, that the counsel for the New York State Medical Association is in error with reference to the corporation laws of the state of Illinois, and is in further error in supposing that congress could confer on you a national organization with the powers indicated, and that he would find (if he looked) that the American Social Science Association is, by the very act creating it, "constituted a corporation by that name in the District of Columbia," assuming all these things to be true, yet they do not afford sufficient reason for suspecting his motives, nor in any manner reflecting on him, other than to show that he is mistaken.

The contention that the amendments to the articles of incorporation (or constitution) and to the by-laws adopted at the Saratoga meeting, in 1902, and ratified at the adjourned session of that meeting, held in Chicago, were not properly adopted, because they were not severally proposed "in open meeting" one year previous to being acted on, nor published at least three times, etc., according to the so-called constitution and by-laws adopted at the St. Paul meeting, in 1901, is erroneous, because:

1. Corporations exist not by natural right, but because they are allowed by the sovereignty (state or national) creating them.

2. No sovereignty (state or national) can give to a corporation created by it, rights and privileges which can be exercised and enforced outside of the jurisdiction of the sovereignty (state or national) creating such corporation.

3. The American Medical Association was incorporated under the laws of the state of Illinois, in 1897. Its meetings for the transaction of business could only legally be held within the territorial limits of the state of Illinois. Therefore, the so-called constitution and by-laws supposed to have been adopted at St. Paul, Minn., were not valid, because not adopted at a meeting held within the state of Illinois.

The amendments to the articles of incorporation voted on at your Saratoga meeting, in 1902, and ratified at the adjourned session of that meeting held in Chicago, were properly made, because the state of Illinois permits such amendments to be made at any annual meeting or at any adjourned session thereof.

As to the propriety of the present by-laws permitting so small a number to constitute a quorum at the adjourned sessions, that is a matter which the Association must decide for itself. If the present number does not correctly represent the judgment of the Association, it should be changed. However, there is nothing in the by-laws to prevent any number, even to the full membership of the Association, attending the adjourned sessions. Nor can I think it probable, as seems to be feared, that even as small a number as constitute a quorum will be likely at such adjourned session to exercise bad faith toward the remainder of the Association.

On the question of a national incorporation, suggested by Dr. Wiggin and strongly urged by counsel for the New York State Medical Association, which Dr. Wiggin says should be procured by a special act of congress, at which "the House of Delegates could complete its business at its annual meeting, wherever it might be held," and which, in the language of the letter from Dr. Montgomery to Speaker Henderson, "would give us the privilege of holding our meeting in any state in the Union while still carrying on the business in Chicago," and in which the advocates have so repeatedly referred to the case of McCulloch vs. State of Maryland, 4 Wheaton, 316, as an authority, and the incorporation of "The American Social Science Association," as a precedent, I have to say:

First. As to the authority: McCulloch vs. State of Maryland, was a suit brought to recover a tax levied under "An act to impose a tax on all banks, or branches thereof, in the state of Maryland," etc., and was a direct attempt, on the part of the state of Maryland, to tax the business of a branch of the "Bank of the United States." The decision of the Supreme Court of the United States involved two questions:

1. Whether congress had constitutional power to incorporate the "Bank of the United States," and

2. Whether the state of Maryland might, without violating the constitution, tax a branch of that bank, located in the state of Maryland.

The case was argued by eminent counsel, including, among others, Mr. Webster and Mr. Pinkney, and the court decided:

1. That *congress has* power to incorporate a national bank, under that branch of the constitution which gives to congress the *power to lay and collect* taxes; to borrow money; to regulate commerce; to declare and conduct a war; to raise and support armies and navies, etc.; and

2. That the state of Maryland could not legally tax the branch of the "Bank of the United States."

This decision has been cited by the Supreme Court of the United States more than one hundred times, and in the various Federal Reports thirty-eight times, so that the case is not at all new or startling to a lawyer in active practice.

It is easy, however, to see a very distinct difference between the *incorporation of a* "Bank of the United States" and an association of this character. The constitution of the United States *confers on congress* the power to make laws respecting the coining of money, etc., and it is easy to see where the Supreme Court found authority for the position that the creation of this "Bank of the United States" was a fit instrumentality to carry into effect the powers distinctly conferred on congress *by the constitution*, but no such power has been conferred on congress with respect to educational institutions, churches or similar institutions.

Congressman Underwood was undoubtedly correct in denying that "congress would have power to incorporate" this Association. *He is also* correct in saying that, "on the other hand, congress has unlimited power to legislate for the District of Columbia, and would have power to incorporate a company for the purpose of doing business within the District of Columbia, and, incidentally, it might transact its business throughout the United States, as all other corporations do, but such a charter would not be a general charter, but would be local to the District, and would have the same limitations on it that charters issued by the state government have."

And now, a reference to the "American Social Science Association": On the 28th of January, 1899, an act of congress was approved, which reads, word for word, as follows:

> An Act to Incorporate the American Social Science Association.
>
> Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That Daniel C. Gilman, Carroll D. Wright, Andrew D. White, Dorman B. Eaton, James B. Angell, William T. Harris, Frederick J. Kingsbury, Oscar S. Straus, Francis Wayland, Saint Clair McKelway, Simeon E. Baldwin, and their associates, members of the voluntary association organized in eighteen hundred and sixty-five and known as the American Social Science Association, and their successors, are hereby constituted a corporation by that name, in the District of Columbia, for the purpose of promoting studies and researches in social science in the various departments in which said association is or said corporation may be organized.
>
> Sec. 2. That this act shall take effect upon its acceptance by said voluntary association at its next regular annual session.
>
> Sec. 3. That the right to alter, amend, or repeal this act at any time is hereby expressly reserved.
>
> Approved, Jan. 28, 1899. 30 U. S. Statutes at Large (55th Congress, 1897-1899), page 804.

It will thus be observed that this act of congress provides that this American Social Science Association "are hereby constituted a corporation by that name in the District of Columbia," and it has, therefore, the same relative territorial limits to its rights and privileges that it would have if incorporated in any other territory or in any of the states of the Union; and, as stated by Congressman Underwood, "such charter would not be a general charter," but is "local to the district," and has "the same limitations on it that charters issued by the state government have."

I have never doubted that an association like ours could be incorporated, by act of congress, in the District of Columbia, but that would carry with it the same limitations with respect to the necessity of holding business meetings within the District of Columbia, that now make it necessary for them to be held in Illinois, and it is more than doubtful whether this would be any improvement over present conditions.

IN CONCLUSION.

The matters considered by your Board of Trustees at its meeting in Chicago on the 20th day of February, 1903, involved:

1. The suggestion that the present articles of incorporation and by-laws, as acted on at your annual meeting in Saratoga and ratified at the adjourned session of that meeting, in Chicago, were not legally adopted, because the changes had not been proposed and published in conformity with the rules of the Association, adopted at St. Paul, in the year 1901, in relation to amendments.

2. That the provisions of the by-laws, fixing a quorum at the adjourned session, permitted too small a number; and

3. That your board ought immediately to take steps to secure from congress a national incorporation, which would give it the privilege of holding your meetings in any state in the Union, and thus "complete its business at its annual meeting, wherever it might be held."

After extended discussion by you, and after you had listened to the presentation of the law applicable to the situation which, as counsel for your Association, I made, your Board of Trustees reached its conclusions with respect to the several propositions, and instructed me to prepare an opinion, setting out, in detail, the situation. This detail is furnished in the previous portion of this letter. A summary of the conclusions reached, with reasons as to each proposition, is as follows:

1. The amendments to the articles of incorporation and the by-laws, adopted at the Saratoga meeting, and ratified at the meeting in Chicago in 1902, are legal. The requirements above referred to—that they should have been proposed "in open meeting" one year previous to being acted on, and published, etc—had no binding validity, because the American Medical Association is a corporation of the State of Illinois. Its meetings for the transaction of business could only be legally held within the territorial limits of this state; therefore, the so-called constitution and by-laws, supposed to have been adopted at St. Paul, and the limitations they provide as to amendments, were not valid, because not adopted at a meeting held within the state within which the Association is incorporated; besides which, the statutes of Illinois expressly permit such amendments to be made at any annual meeting or at any adjourned session thereof.

2. As to the propriety of so small a number constituting a quorum at an adjourned session, that is a matter which the association must decide for itself. There is nothing in the by-laws to prevent any number, even to the full membership of the Association, attending the adjourned session, if they so desire; nor does it seem probable that so small a number as constitutes a quorum will be likely, at such adjourned session, to exercise bad faith toward the remainder of the Association.

3. The board decided that it was not its duty to take steps toward securing the proposed national incorporation, because:

(a) It seems very clear that congress has no power to create a national incorporation for the purposes mentioned in the charter of our Association, and to give to such Association the power to do business in any of the states or territories of the Union.

(b) While congress undoubtedly has the power to create, by special act, a corporation of this kind, and has, in fact, created somewhat similar organizations, among which is "The American Social Science Association," yet, when created, such corporations are (as is the American Social Science Association) only a corporation of the District of Columbia, and not national, and such corporation would have the same territorial limitations on it as would have charters issued by the various state governments, so that whether the Association be incorporated in the District of Columbia or in some of the other states or territories of the Union, it would be necessary to have its meetings, for the transaction of business of the corporation, held in the District of Columbia or in the state or territory in which it is incorporated. This, however, does not prevent other meetings being held for other purposes outside the state or territory creating the corporation. Precisely that condition exists to-day, so that unless it would be more convenient for you to hold your meetings for the transaction of the business of the corporation in the District of Columbia than it is to hold them in the state of Illinois, there would be nothing gained by the proposed change. In addition to this, your attention was called to the fact that as Trustees for the American Medical Association, a corporation of the state of Illinois, having large property interests here, you were, in fact, trustees for the entity—the Association—and for its various members bound to preserve its and their property in this corporation, and that you would be justly censurable if, without unanimous consent, you took measures involving the expense and uncertainty of securing the proposed corporation to take the place of the present one.

Yours truly,
JESSE A. BALDWIN.

REPORT OF THE COMMITTEE ON PROPHYLAXIS OF VENEREAL DISEASES.

Dr. Ludwig Weiss, chairman, read the report of his committee as follows:

To the President and House of Delegates of the American Medical Association: Gentlemen—The Committee on Prophylaxis of Venereal Diseases begs leave to submit the following report:

The Committee elected Dr. Henry D. Holton of Brattleboro, Vt., Chairman, and Dr. Ludwig Weiss of New York, Secretary.

Several meetings were held by correspondence; and in order to expedite matters, it was agreed on to appoint Drs. Holton, Bulkley and Weiss as a sub-committee with power to act. Dr. Frank H. Montgomery of Chicago resigned his membership on account of leaving the country, and Dr. Frank Billings, President of the American Medical Association, appointed Dr. Louis E. Schmidt, Chicago, to fill his place.

The scope of the work which the Committee has set before itself consisted at first in corresponding through its Secretary with medical men and philanthropists, with the view of gathering such information and suggestions as they may have had to offer. This step, however, did not seem productive of what the Committee considered helpful hints. It did not elicit new facts and only gave occasion to ventilate different and uncompromising views, which, while proper before an assembled body like a congress, did not open new avenues to aid the Committee in its preliminary work.

In looking for another more promising basis for its studies, the Committee has very keenly felt the utter want of statistics from boards of health, etc. There was absolutely nothing on which to build, or from which to draw conclusions. While other contagious diseases are controlled and combated by boards of health with great vigor and excellent results, venereal diseases are ignored by our sanitary authorities, and the morbidity therefrom is consequently not a matter of record; officially, there are no venereal diseases in these United States.

There remained only one other source of information, viz., the utilization of the records of the different municipal and general hospitals in the larger cities of the union. But this task would have needed a large clerical force and a substantial appropriation to cope with. It was, however, tried tentatively in many instances and proved futile.

The returns were utterly disproportionate to the number of inquiries sent out; but, had they all replied, as will be seen later, the statistics therefrom would not have proved of great value. In most general hospitals, venereal diseases are not treated; or, if so, those cases figure under different names, pertaining to the late manifestations of these diseases. This had been the experience of the Committee of Seven appointed by the Medical Society of the County of New York in 1901, for the study of measures for the prophylaxis of venereal diseases. Furthermore, the imperfect records, the various designations and omission of diagnosis and other necessary particulars for fairly definite statistics would have made it illusory to draw conclusive statistics.

These sources, while they yield interesting deductions, do not represent the amount of venereal diseases treated in the public institutions.

Your Committee then decided to enlist the help of the medical press of the country, and to this end issued a circular letter, with a request to support the movement.

Your Committee embraces this opportunity to extend publicly its thanks to the medical journals for the readiness with which the appeal was given place in their columns, either in extenso or in abstract. Without their powerful aid, surely a movement like this must fail; with their co-operation, it has a good chance to succeed.

Simultaneously with this move and in order to ascertain any laws in regard to prostitution and free treatment of venereal diseases, your Committee drafted the following questions and assigned to each member a division of the United States, so that every state and territory was covered. The following questions were asked of the different states:

1. What laws exist in the different states relating to prostitution?
2. Is there a sanitary marriage law which provides for medical examination of the contracting parties?
3. Is there any law against wilfully or knowingly communicating venereal diseases?
4. What, if any, municipal regulations exist in any city of your state regarding these diseases?
5. Is notification required of these diseases in your state?

Up to the time of completion of this report, 20 states have responded, and many more are confidently expected to do so. But even from this limited number, the utter lack of laws to combat venereal diseases can be ascertained.

The following is a summary of the returns from the states which have responded, viz.: Arizona, Connecticut, Colorado, District of Columbia, Maine, Maryland, Massachusetts, New Hampshire, North Carolina, New York, Ohio, Oregon, Pennsylvania, Rhode Island, Utah, Virginia, West Virginia, Washington, Vermont.

Each of these states, with the exception of Rhode Island and Connecticut, has, in answer to question 1, the usual laws and sundry police regulations of general character against houses of ill fame, including specified nuisances therein against soliciting in streets, and against enticing of females under 16 years. To questions 2, 3, 4 and 5, the answer in all instances as far as relating to venereal diseases is negative.

It is gratifying to note that this circular letter elicited a number of responses from physicians, medical associations and health officers. Through the latter source, we could ascertain that, independently of the general state laws, some municipalities have their separate local laws or ordinances regarding the social evil.

The fact that states and municipalities in most instances have different laws on this question, as is the case in several states, made the task of gathering reliable facts one of great difficulty.

In order to ascertain the extent of such divergencies and also to become acquainted with the different ways municipalities settle this question, your Secretary has issued a circular letter to the health officers of the forty largest cities of the United States. The letter and questions are herewith appended:

> Dear Sir:—The undersigned, Secretary of the Committee on Prophylaxis of Venereal Diseases of the American Medical Association, takes the liberty of requesting you kindly to answer the following questions, to be used by the Committee for compiling statistics.
>
> The Committee is already in possession of data on this topic emanating from the state authorities; but, inasmuch as there seem to exist in several large cities separate laws governing these questions, independent of state laws, the Committee would be greatly indebted to you, if you would kindly furnish it the data embodied in its questions.

As the Committee has to report at the next—New Orleans—session of the American Medical Association, May 5-8, a prompt answer would greatly oblige.

Very truly yours, L. Weiss, Secretary.

1. Is there any law or ordinance in your city relating to prostitution? If so, what are its provisions?

2. Is there any law for wilfully or knowingly communicating venereal diseases?

3. What, if any, municipal regulations exist in your city regarding these diseases?

4. What are the accommodations and the number of beds for venereal patients in the hospitals under the jurisdiction of the health board of your city?

At this writing, the following twenty cities have been heard from: Albany, Baltimore, Buffalo, Cleveland, Detroit, District of Columbia, Louisville, Lowell, Minneapolis, Newark, New Orleans, New York, Philadelphia, Pittsburg, Providence, Rochester, St. Paul, Syracuse, St. Louis, Scranton, Worcester.

The summary of these answers elicited the fact that as to question 1, there are in existence the police regulations of the general character, confessedly a dead letter; Detroit and Cincinnati have a regulation on the continental plan. Questions 2 and 3 are in each instance answered in the negative, and as to question 4, there is the usual scarcity of beds for venereal patients, in some cases absolutely out of all proportion to the number of inhabitants.

That the interest towards the recognition of venereal diseases is increasing and that the profession is conscious of the great social danger from it, is shown by the activity of different medical societies in this direction. Among others may be mentioned the State Medical Association of Maine, which had a committee appointed to study the expediency of adding syphilis and venereal diseases to those required to be reported to the boards of health. It will instruct its delegate to vote in favor of a congress. The Missouri Valley Medical Association passed a resolution unanimously endorsing this progressive movement of the American Medical Association, appointing a committee of three to aid this Committee in every way, if so desired. Your Secretary has extended thanks for the offer.

A similar movement was contemplated by the state and provincial boards of health of Vermont. The secretary of the State Board of Health of Iowa expressed his hearty sympathy with the Committee's efforts looking towards the prophylaxis of venereal diseases.

The Board of Health of the City of New York expressed its interest in the matter and hopes that the department can take some action regarding it. The chancellor of the University of Nebraska expressed his sympathy with the movement tending to combat the spread of venereal diseases and most of the city officials to whom the above questions were sent expressed their sympathy with the movement and promised to take steps for municipal control of venereal diseases.

After having passed in brief review the steps taken by your Committee, we may be permitted to deduce from our preliminary study such facts as may perhaps prove of some value or importance in the further consideration of this question. The Committee does not commit itself to anything except the opinion that it regards the prophylaxis of venereal diseases as of sufficient moment to receive deliberate and careful consideration by this honorable House of Delegates.

The dire consequences of venereal diseases do not only affect the working and earning capacity of the people, but also their well being. The well being of the people is encroached on not so much by the active incidents of these diseases, but much more through their chronic manifestations, especially in women. The tedious and invalidating course of chronic pelvic inflammations, their painful and ever-recurring accidents diminish the exercise of motherly care of the children, forces to relative or absolute inactivity the helpful mate. The working capacity being thus diminished, of course, the earning capacity suffers also, and the type of an ill-nourished, careworn and poverty-stricken family is established. And as poverty and squalor are the stranglers of morals, virtue in the children takes its leave, the demon alcohol takes possession of the despairing husband and father, and mute resignation and despair dulls the sensibilities of the wife and mother.

It has been approximately determined that among the communicable diseases in Prussia, typhoid represents a yearly money loss of 8,000,000 marks, while the increased expenses and decreased income caused by venereal diseases amounts to 90,000,000 marks yearly, an amount which supersedes that caused by consumption. But the financial loss is of minor importance compared with the enormous social danger and consequent social misery. Gonorrhea, especially its latent form, destroys the procreative functions in both sexes; in men through chronic inflammation of the adnexa, causing a zoospermia and necrospermia (and further stricture and ascending inflammation of the kidneys). In women through most serious involvement of the pelvic generative organs and their adnexa, destroying fecundity and giving rise to mutilating surgical operations. Eighty per cent. of all deaths from pelvic diseases in women are due to gonorrhea. Twenty per cent. of all blindness is due to gonorrheal infection of the newborn. Fifty per cent. of all involuntary childless marriages are caused by gonorrhea of the female organs of generation, of which 45 per cent. are due to marital infection by men. Taking this view of the existing conditions, the mooted question of "race suicide" so eminently emphasized of late as a voluntary cause of barren marriages, finds its explanation in a quite unexpected but entirely natural, if even in a not quite as voluntary a way as was generally presumed.

The original source of this gonorrheal infection is traceable in about 70 per cent. to prostitutes, and as 80 per cent. of all men had had gonorrhea once or several times, the conclusions reached are obvious.

While almost every prostitute must be looked on as infected with gonorrhea, compilations have shown that about every fourth disseminates syphilis. This means that syphilis is about four times rarer than gonorrhea. But, notwithstanding, it stands higher in its fatality. With lessened morbidity it unites a more profound activity in the visceral organs; it is always a constitutional infection with a high mortality and transmissible through heredity. In contradistinction to gonorrhea, it can be acquired also in a non-venereal way. In countries of inferior culture, it is disseminated in nine-tenths of all cases in an extragenital way. Syphilis insontium is acquired in about 5 per cent. of all cases. It causes abortion in from 60 to 80 per cent., and propagates this tendency up to the third generation. Marital infection takes place in about 5 per cent. of syphilitic women and from 60 to 80 per cent. of this is due to prostitution.

There are, according to some authorities, 150,000 syphilitics in Berlin, or 12 per cent. of the inhabitants; in Paris, from 13 to 18 per cent. In Copenhagen, 1 of every 55 young men of the age between 20 and 30 has syphilis and 1 in 8 has gonorrhea. In the City of New York the number is estimated to reach 200,000. The same ratio holds good with very little oscillations in every capital or large city.

An approximate idea of the prevalence of venereal diseases can be gotten from the records of the various armies. There, from a body of men living under almost similar social conditions and with every case duly reported, the morbidity from venereal diseases can easily be ascertained. Although very valuable, these statistics, however, do not elucidate conditions in the great mass of the population.

As to the armies, these are the figures per thousand:

Germany	27	Austria	65
Russia	43	Italy	71
France	44	Great Britain	204

(Parliamentary Report, July 15, 1897, made by the Earl of Dunraven.)

The admission rate for the whole army of the United States for 1901 was 133.97 per 1,000. In the Philippines, those diseases have increased materially in their prevalence. In 1901 they constituted 20.42 per cent. of the total sickness, as compared with 8.97 in 1900. In consequence of this dire condition, medical inspection of the troops at regular intervals and reglementation of the prostitutes has been instituted there. The navy of the United States, i. e., the force afloat, participated with 112 per thousand, against 119.7 of the German navy.

A much more reliable statistic, because embracing the whole population, can be gathered from Sweden and Denmark, where, since 1874, venereal diseases are among the reportable contagious diseases. Physicians there are held to make weekly returns. Every venereal patient is obliged to have himself treated and treatment is given gratuitously. Statistics there show that since 1887 the number of venereal diseases has diminished 34 per cent. In the Dukedom of Braunschweig, where every hospital is open for those afflicted with venereal diseases, constitutional syphilis has greatly diminished in proportion to other venereal diseases.

The latest and most original departure to ascertain the prevalence of venereal diseases was instituted by Prussia. By request of the Government, all venereal diseases coming into treatment on the 30th day of April, 1900, had to be collected by physicians and their reports returned for statistical purposes. It appears, then, that on this day there were in the Kingdom of Prussia 40,920 venereal patients under treatment. (Seventy-five per cent. males and returns and in consequence of other errors the real number of 25 per cent. females.) Among which were 11,000 cases of recent syphilis. But since, only 63 per cent. of all physicians made venereal patients on this day would amount to 64,000, making a yearly aggregate of 773,000 and possibly more venereal patients. This means that in Prussia three-quarters of a million people are afflicted yearly from venereal diseases; or that, out of 22 adults, 1 becomes infected every year. By computation, it has further developed that in Berlin, among men who marry after their 30th year, every one had gonorrhea twice and every fifth was infected with syphilis. These are appalling numbers and far outdistance even consumption.

Finally, we will scan cursorily the hospital facilities of different countries for the treatment of venereal diseases.

In Prussia, every 29th venereal patient is admitted to the hospital. The other 28 must either content themselves with dispensary treatment or fall into the hands of quacks. In all Germany only 7 per cent. of venereal diseases are admitted to the hospitals.

The main cause of this dereliction lies everywhere in the insufficient supply of hospital facilities and that most general hospitals do not admit venereal patients, or only occasionally so; and in the contemptuous and unkind treatment of patients so afflicted. The poorest accommodations, the meanest food are given them and no wonder that they try to avoid the hospital terror.

We must, in order to combat venereal diseases, first sterilize its sources, and this can only be done by early and judicious treatment of the afflicted.

London has one general hospital bed for each 1,000 of its population. New York, one bed for each 5,000. London treats 88 per cent., New York only 9½ per cent. of its infectious diseases in hospitals. In order to effectually cope with venereal diseases, London ought to have for its 6,300,000 inhabitants about 2,500 beds for venereal patients, and Greater New York, with its 3,500,000 inhabitants, at least 1,800 beds at its disposition.

In the northern countries of Europe where venereal diseases are classed among the reportable ones, and gratuitous treatment and generous hospital facilities are within reach of every one, venereal diseases have greatly diminished.

Stockholm is in the enviable position of having more beds than needed (366), and complains only of the lack of polyclinics for outdoor patients. In Hungary, the treatment of sick prostitutes as outpatients is strictly forbidden and hospital treatment required; transmission of venereal diseases is made punishable. Punitive legislation against wittingly communicating venereal diseases is in existence in Norway, Denmark and Finland. The countries of middle Europe have no such laws yet.

The foregoing fragmentary statistics will convincingly prove that venereal diseases stand next to tuberculosis and alcoholism, if not superseding them. They are permeating the very root of the population, as 15 to 20 per cent. of adult males are infected with syphilis, and about 80 per cent. of them had gonorrhea, tainting those yet unborn, maiming those born with the virus already in their blood, deteriorating the race, devitalizing the individual.

The dangers from venereal diseases to the people, their socio-economic importance, their causing premature invalidism are of sufficient moment for all governments to exert their utmost to cope with them.

Gentlemen of the House of Delegates: It is a grave responsibility which rests on the shoulders of the medical fraternity. It is a complex and intricate question, consisting of ethico-moral and sanitary-medical components, which forces itself inevitably and in an ever recurring way to the attention of the medical profession. To shirk it, we must not. To evade it, we dare not. To pass it over in silence, we can not!

We are brought face to face daily with the primary and late manifestations of venereal diseases, their devastating influence on the affected, on the family and on the well being of the people in general.

In combating them, we must not fail to take into consideration both components of the question, although in our dealings the sanitary side will be of paramount interest. We can do an enormous amount of good by inculcating in the young sexual purity, respect for women and the possibility of continence. On the other hand, we must insist, in order to combat the spread of the disease and to sterilize its sources, that larger hospital and dispensary facilities should be made available. There has been a most effectual crusade instituted against tuberculosis everywhere. Through a high tax license the barriers against alcoholism are raised. Only against the third curse of humanity—venereal diseases—there is a lack of action, a sin of omission, almost as bad as the sin of commission of sexual profligacy. The legislator does not legislate, the registrator (of the boards of health) does not register it, the hospital does not house it! As Bulkley puts it—ignored through ignorance, neglected through negligence of our duty! So, ostracized and outclassed, venereal diseases, through ignorance, false shame, concealment, prejudice, carry on their slaughter unhampered, unchecked and undisturbed, devastating coming generations, ruining the present one.

Your Committee would most strenuously emphasize the fact that, in its labors, it has not taken any stand, neither *pro* or *con* regarding the licensing or suppression of the social evil. True to the wording of the resolution, it has confined its studies only to the question whether the enormous spread of venereal diseases could be inhibited by a systematized action emanating from the profession. It has come to the conclusion that, looking at it from whatever point of view, it is the medical profession which will have the decisive word in the premises. It is convinced that the profession, to which the first and ultimate appeal for help is made by the afflicted, is, in consequence of its intimate relation to the physical ailments of humanity, well able to cope with both components of the question. The unselfish perception of its duties will and always did prompt the medical profession to exert an educational as well as sanitary influence towards the diseased in body and towards those morally dejected.

Your Committee, therefore, is impressed that, inasmuch as only a concerted action is promising of results, it is incumbent on the medical profession to discuss and recommend means and ways against the great and growing danger of the most serious and lasting of all contagious diseases that afflict humanity. It most respectfully recommends to the honorable House of Delegates that a national congress for the prophylaxis of venereal diseases should be convened under the auspices of the American Medical Association. This will mark an epochal event in the history of this great national body of medical men, to have contributed their mite towards the welfare of the people, by endeavoring to check the spread of some of the most persistent and virulent poisons conveyed into the blood of the people. Your Committee respectfully submit, in a preliminary way, the following points which would serve as a basis for such a congress.

First.—As the states can not with impunity ignore the existence of venereal diseases, and as it is the duty of the state to protect the people from the ravages of contagious diseases, there should be instituted through the state and district societies a propaganda of action in each state or district society looking towards a proper recognition of venereal diseases by the different legislatures.

Second.—That the American Medical Association authorizes its accredited delegates from each state, or by appointing special committees for this purpose, to organize such a movement in their respective state and district societies and to send delegates to such a congress.

Third.—That such delegates may then, fortified by the authority of the American Medical Association, in such a congress convened, bring to bear on their home legislature the necessity of legislation against the spread of venereal diseases.

Fourth.—To appoint a central committee of organization to be in touch with the various state committees.

The congress would discuss and act on the following questions:

SOCIAL MEASURES.

Prostitution.—Its causes and how to diminish its extent. (*a*) Safeguarding minors. (*b*) By raising the age of consent. (*c*) Socio-economic measures. (*d*) Educational measures. (*e*) Creation of a provident education law.

SANITARY MEASURES.

Prophylaxis by Treatment.—(*a*) Making venereal diseases reportable without giving names and addresses, solely for statistics of morbidity. (*b*) Liberal and enlarged hospital and dispensary facilities, with gratuitous treatment.

LEGISLATION.

(*a*) State laws against diffusing syphilis and venereal diseases in an extragenital way. (*b*) Certifying the health of wet nurses. (*c*) Regulating the profession of ritual circumcisors, of barbers, of dentists. (*d*) Trade sanitary laws against transmission of syphilis (glassblowers, cigarmakers, manicurists, etc.).

INDIVIDUAL PROPHYLAXIS.

(*a*) By teaching the avoidance of dangerous contact. (*b*) By instructing the diseased how to avoid infecting others.

MISCELLANEOUS MATTERS.

(*a*) Recommending a uniform nomenclature. (*b*) Broader education of medical students in venerology. (*c*) National and international statistics. (*d*) To petition the Congress of the United States for the creation of a Cabinet position to be called Department of Health. (*e*) Creation of societies to wage battle against the spread of venereal diseases like the Société Internationale de Prophylaxie Sanitaire et Morale, in Brussels, in connection with the international conference held there. And the German society of Berlin for combating venereal diseases; with periodicals issued by such societies.

The name of the congress to be National Congress for the Prophylaxis of Venereal Diseases, under the auspices of the American Medical Association. Respectfully submitted,

Henry D. Holton, Ludwig Weiss, George M. Kober, W. H. Sanders,
L. Duncan Bulkley, Louis E. Schmidt, Committee.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Asthma.

The following combination appears in the "Indian Med. Record," and is recommended in the treatment of bronchial asthma:

℞.	Pot. iodidi	gr. x		65
	Spts. ammon. arom.	m. xx	1	30
	Spts. etheris sulph.	m. xx	1	30
	Tinct. belladonnæ	m. x		65
	Aquæ camphoræ	℥i	30	

M. Sig.: To be taken at one dose.

The author places emphasis on the good effects of the potassium iodid, especially in those cases accompanied by a bronchitis. The dose of this preparation may be repeated three or four times a day, and gradually increased to thirty (2.00) or forty (2 65) grains at a dose.

He recommends it given in a glass of milk, without any admixture of syrup and on an empty stomach. When combined with potassium carbonate the iodin is not set free in the stomach, and consequently prevents disturbance of that organ. It may be combined with ammonium preparations which act on the skin and so relieve the mucous membranes.

Poulet, in "Bul. Gen. de Ther.," recommends the following combination containing oxalic acid in the treatment of asthma and capillary bronchitis:

℞.	Acidi oxalici	gr. xxx	2	
	Sodii bicarb.	gr. xlviii	3	20
	Syr. aurantii	℥ii	60	

M. Sig.: One tablespoonful every hour.

In ordinary forms of bronchitis, "Press Medical" recommends the following:

℞.	Thiocol	gr. xxx	2	
	Sodii benzoatis	gr. xxx	2	
	Tinct. aconiti	m. xx	1	30
	Aq. laurocerasi	ʒiiss	10	
	Syr. senegæ q. s. ad	℥v	150	

M. Sig.: One tablespoonful three times a day.

Robin recommends the following in chronic bronchitis:

℞.	Antimonii oxidi (white)	gr. viii		50
	Syr. ipecac.	ʒii	8	
	Terpin hydratis	gr. iii		20
	Dionin	gr. 1/6		01
	Mist. acaciæ	℥iv	120	

M. Sig.: One tablespoonful several times a day.

Iodin Solution for Furuncles.

According to an abstract in the "Med. Standard"' Gallois and Courcoux recommend the employment of a concentrated solution of iodin in acetone in the treatment of boils, as acetone will hold in solution four times as much iodin as alcohol. The following formula is advised:

℞.	Iodi (metallic)	ʒi	4
	Acetone	ʒiiss	10

M. Sig.: Apply locally to the inflamed part.

This preparation produces only slight pricking sensation to the unbroken skin, but sharp pain is experienced if applied after the boil is opened. It is claimed that a boil, by this means, may be arrested before it reaches the suppurative stage.

Effects of Tight Diapers.

Dr. Alfred C. Cotton, in an article in "Arch. of Ped.," condemns the effects of tight diapers as being the cause of deformity by compression on the tissues which are still in the formulative period. Skiagraphs are given, showing the results of pinning diapers of firm, unyielding substance tightly around the the pelvis, thus producing a retardation of its growth. The thorax, according to the author, may likewise be constricted. Genu valgum may be produced by wadding a lot of diaper material between the thighs. The material should be light, made of absorbent cotton, covered with cheese cloth. The clothing should be supported from the shoulders. Knitted, seamless underclothing may be worn.

Pertussis.

The following combination is recommended by the "Month Cyc. of Med." as a local application in the treatment of pertussis:

℞.	Acidi carbol. crys.	gr. xv	1
	Sol. cocainæ hydrochlor. (2 p. c.)	m. lxxx	5
	Glycerini	ʒiv	15

M. Sig.: To be brushed over the pharynx before or between the paroxysms.

Yeo recommends the following combination as a favorable mixture in lessening the severity of the paroxysm and rendering the mucous less tenacious:

℞.	Sodii benzoatis	gr. lxxii	5	
	Sodii bicarb.	gr. xlviii	3	20
	Ammonii chloridi	gr. xxiv	1	65
	Aquæ chloroformi	℥i	30	
	Aquæ anisi q. s. ad	℥iii	90	

M. Ft. mistura. Sig.: One to four teaspoonfuls, according to the age of the child, in a little hot milk, every four hours.

Syphilis.

The treatment of syphilis, according to W. D. Trentwith, in "Med. News," should be divided into four stages, as follows:

1. The pre-eruptive period.
2. The eruptive stage, including the first six or seven months.
3. From the sixth or seventh month to the end of the second or third year.
4. The tertiary stage.

In the pre-eruptive stage attention should be given to the general condition of the patient. Smoking or chewing tobacco and the use of alcoholics should be stopped and the patient given plenty of fresh air and a nutritious diet. If the chancre does not properly heal it should be washed with castile soap twice a day, followed by a 1 to 2,000 bichlorid solution and that followed by an application of lint saturated with the same solution or a 50 per cent. solution of lotio nigra. If an indurated nodule remains after the sore has healed, the author recommends the application of a 50 per cent. mercurial ointment. In the same way an application can be made to the inguinal glands as soon as any enlargement is made out, applying about gr. 15 (1.00) of the ointment and rubbing it in well each night. The mouth and teeth should be carefully looked after in order to prevent lesions in the oral cavity if possible. As an antiseptic tooth powder he recommends the following:

℞.	Potass. chloratis	℥ss	15	
	Pulv. saponis	℥iss	45	
	Olei gaultheriæ	m. iii		20

M. Sig.: As a tooth powder; or:

℞.	Potassii chloratis	ʒi	4
	Aquæ	℥viii	240

M. Sig.: As a mouth wash, to be used several times through the day.

In the eruptive stage the treatment should be promptly carried out. It is on the new, young cells, according to the writer, that mercury is most destructive, so that loss of time in its administration diminishes to that extent the patient's chance for recovery. He sometimes begins with the protoiodid of mercury in doses of gr. 1/8 (.008) to gr. 1/4 (.0015) three times a day. This may be continued two or three weeks. He prefers, however, inunctions rubbed thoroughly into various portions of the body, naming the ten or eleven selected areas, not omitting the spaces between the fingers and the toes, the palms of the hands and the soles of the feet. A 50 per cent. mercurial ointment is used so divided that thirty or forty grains may be used at each inunction. The patient is instructed to take a warm bath daily or to cleanse the region to which the ointment is to be applied and then thoroughly rub it in; from fifteen to thirty minutes being required before all the ointment disappears.

Each part of the body should serve its term until the body is entirely covered; at the same time the indications of too large doses should be watched for, such as salivation, anemia, loss of weight, etc., when the ointment should be omitted for a few days and again resumed in smaller doses. Elimination by the bowels must be carefully inquired into.

If no untoward symptoms arise the daily amount of the ointment may be raised to gr. 45 (3.00) and finally to gr. 60 (4.00). The inunctions are stopped, and after one or two days potassium iodid begun, commencing with ten drops (.65) of a saturated solution, well diluted and gradually increasing it to twenty (1.20) or twenty-five drops (1.65) three times a day. This should be continued for 15 or 16 days, when the inunctions are repeated for 10 to 11 days, followed by the potassium iodid for 15 or 16 days. This plan should be carried out until the sixth or seventh month, in which time the entire body will have been covered from seven to twelve times. The author then advises a rest of three or four weeks, when he places the patient on the following mixed treatment:

℞.	Hydrarg. biniodidi	gr. 1/30-1/24		002-.0025
	Potassii iodidi	gr. v-xv		30-1.00
	Aq. destil. q. s. ad	ʒi	4	

M. Sig.: At one dose, to be repeated three times a day in plenty of water. The foregoing mixed treatment is prescribed, with intermissions, occasionally, of three to four weeks, until twelve or thirteen months have passed, after which time potassium iodid is given, in doses reaching gr. 50 (3.30) to gr. 60 (4.00) three times a day, about two months out of every four, and changing to the mixed treatment at times. This treatment is continued to the second year, when no bad signs being present the treatment may be stopped and the patient kept under proper observation.

For the treatment of mucous patches the author recommends an application of a 5 per cent. solution of silver nitrate every other day and the use of a gargle as follows:

℞.	Hydrarg. bichloridi	gr. iii		20
	Tinct. myrrhæ	ʒss	2	
	Aquæ destil. q. s. ad	℥viii	240	

M. Sig.: As a gargle; or:

℞.	Alumeni	ʒi	4
	Potass. chloratis	ʒiss	6
	Aq. destil.	℥viii	240

M. Sig.: To be used as a gargle.

The treatment of salivation should consist in stopping the inunctions, moving the bowels with salts (either Rochelle or Epsom). In cases where syphylides or gummata reappear large doses of potassium iodid are given internally and inunctions applied or calomel fumigations may be employed or a local application applied as follows:

℞.	Hydrarg. bichloridi	gr. i		06
	Collodii	℥i	30	

M. Sig.: Paint over the affected area and renew from time to time.

As a fumigation the following:

℞.	Hydrarg. chloridi mitis	gr. xx	1	30
	Cinnabar	gr. xl	2	65

M. Sig.: As a fumigation.

Fumigation and the hypodermic method are both of value when other methods fail.

Tabes Dorsalis.

Dr. C. Pope, in the "Alienist and Neurologist," states that he has never seen any benefits derived from mercury in either large or small doses, nor from a course at Hot Springs, but on the other hand untoward results have been observed. The only preparation from which he has obtained the expected results is silver nitrate in doses of grain 1/6 (.01) to 1/4 (.015) given three times a day, one or two hours after each meal. The crisis is best treated by morphin, used with great caution. Strychnin should be rarely used, and when given it should be administered in very small doses.

Peritonsillar Abscess.

The following is recommended by the "Phil. Med. Jour." in the treatment of quinsy:

℞.	Ichthyol	ʒiii	12	
	Ung. belladonnæ	ʒii	8	
	Olei citronellæ	m. iii		20
	Adipis lanæ hydros.	ʒiii	12	

M. Sig.: To be applied externally.

Medicolegal.

Power of Board to Revoke License for Immoral Conduct.—Chapter 254 of the Laws of Kansas of 1901 provides, among other things, that the state board of medical registration and examination may refuse to grant a certificate to any person guilty of felony or gross immorality, and may, after notice and hearing, revoke the certificate for like cause. The Supreme Court of Kansas says, in the case of William M. Meffert vs. the State Board of Medical Registration and Examination, that a surfeit of authority might be cited holding that the state, in the exercise of its police power, may prescribe the qualifications which a physician must possess before entering on the practice of medicine or surgery. The State Board of Medical Registration and Examination is not a judicial tribunal; while it may be said to act *quasi* (as if) judicially it is only a ministerial board and performs no judicial functions. It is classed with such boards as the county boards of equalization, boards for the examination of applicants for teachers' certificates, city councils in granting and refusing a business or occupation license, and numerous other boards of similar character. Such boards perform no judicial functions, are not judicial tribunals, and have never been classed as such. It was contended that the procedure before the board in the admission and rejection of evidence was violative of the rights of Meffert, in that the evidence received and acted on was made up largely of unsupported accusations, hearsay and street rumor, and was not sufficient to sustain the findings. The provisions of the act creating the board, the court goes on to say, plainly indicate that such investigation was not intended to be carried on in observance of the technical rules adopted by courts of law. The act provides that the board shall be composed of seven physicians. These men are not learned in the science of law, and to require of a board thus composed that its investigations should be conducted in conformity to the technical rules of a common law court would at once disqualify it from making any investigation. It is subversive of the morals of the people and degrading to the medical profession for the state to clothe a grossly immoral man with authority to enter the homes of her citizens in the capacity of a physician. It was the intention of the legislature to adopt a summary proceeding by which the morals of the people and dignity of the profession might be protected against such a possibility without being embarrassed by the technical rules of proceedings at law. Meffert was timely notified of the charges preferred against him and the time when a hearing would be had and was given ample opportunity to refute such charges. The findings by the board are conclusive on this court. Next, it was contended that the immoral conduct with which this party was charged was not practiced in the line of his profession, therefore not cognizable by the board, and the court says that it only mentions this contention to condemn it. The law is not that the board must find that such person has been grossly immoral with his patients, but that he is grossly immoral in his general habits. The object sought is the protection of the home of the sick and distressed from the intrusion therein, in a professional character, of vicious and unprincipled men—men wholly destitute of all moral sensibilities. It was not the purpose of the lawmakers to clothe a man with a certificate of moral character and send him out to prey on the weak and unsuspecting, on those who would be entirely at his mercy, and quietly await the accomplishment of that which observation and experience has taught us is certain to follow before depriving such person of the endorsement which gave the opportunity to commit such wrong. The law disqualifies one guilty of a felony. It would hardly be contended that the felony for which a license may be revoked must have been committed on a patient or against the property of a patient, or while such physician was attending a patient. Nor does the court agree with the contention that to deprive a physician of his right to practice medicine otherwise than by a judgment or forfeiture by a judicial tribunal violates the fourteenth amendment to the constitution of the United States, which forbids any state to deprive any person of property without due process of law. It says that we have seen that it is within the police power of a state to prescribe the qualifications of one desiring to practice medicine, and also to provide for the creation of a board or tribunal to make the examination and determine whether the applicant for a license to follow this profession possesses the required qualification, and, if so, to issue to him such license. It must follow that the state may confer on the same board or tribunal the power to revoke such license, if it should thereafter be made to appear that the license should not have been issued, or if for any reason the holder thereof since its issuance had become disqualified. This constitutional provision is not a restriction or limitation on the police power of the state to pass and enforce such laws as in its judgment will inure to the health, morals or general welfare of its people. Such power is reserved to the state, and has been so recognized by all courts since the adoption of this amendment. Another contention was that the state board of medical examiners had no power to revoke the license theretofore issued, because the acts for which the commission was revoked, if committed at all, were committed before the passage of the law creating the board and, therefore, as to such acts the law was *ex post facto*. But the court says that an *ex post facto* law is meant one which imposes a punishment for an act that was not punishable at the time it was committed or imposes an additional punishment to that then prescribed, etc. The revocation of a license to practice medicine for any of the reasons mentioned in the statute was not intended to be, nor does it operate as a punishment, but as a protection to the citizens of the state; such requirements go to his qualifications, and where the qualification imposed is reasonable, one has no right to complain that he is deprived of the right to practice his profession because he has not conformed to such reasonable regulations. If the revocation was intended as a punishment, there might be force in this argument, but, since the only purpose of the law was to require a certain standard of morals of the physician, the argument is without force.

April 25.

1 Problems in Sanitation. Henry D. Holton.
2 *The Association of Tabes and Multiple Sclerosis: Report of a Classical Case of Tabes with Intention Tremor and Nystagmus. Charles J. Aldrich.
3 *The Curative Powers of the X-Rays upon Lupus and Malignant Growths, with Reports of Cases. Thomas J. Buchanan.
4 *Splenic Anemia, Note of a Case. A. L. Benedict.
5 Report of a Case of Cranial Fistula Cured by Operation. J. A. Keown and E. B. Schallenbach.

2. **Tabes and Multiple Sclerosis.**—The case reported by Aldrich gives a perfect type of intention tremor with nystagmus in a classical tabetic, yet, in view of the man's age and the fact that we may have nystagmus in locomotor ataxia as well as motor irritations and intention tremor, he sees no necessity of complicating our pathology by assuming simultaneous existence of the two diseases.

3. **The X-Rays.**—Buchanan reports and illustrates a case of epithelioma and lupus treated by the *x*-rays. He holds that they act in carcinoma largely through disturbance of the trophic nerves supplying the blood vessels and skin and interfering with the blood supply of the neoplasm with subsequent atrophy. His conclusions are given as follows:

1. Superficial epitheliomata, lupus, rodent ulcers, eczema and many kindred skin affections can positively, in many cases, be cured with the *x*-rays.

2. The growth of deep-seated carcinomata can sometimes be retarded, and the pain very much lessened by means of the *x*-rays, but that such patients can be permanently cured is, as yet, not demonstrated.

3. A tube of medium-high vacuum is better suited for *x*-ray therapy than a tube of low power, particularly for deep-seated carcinomata.

4. The part exposed should never be nearer the tube than 12 inches.

5. An exposure should never last longer than 5 or 10 minutes at one sitting.

6. An interval of three or four days should intervene between each sitting.

7. In order to produce a cure it is neither necessary to produce a burn nor to cause any reaction whatever.

8. All cases of inoperable carcinomata, sarcomata, etc., should be treated with the *x*-rays before they are abandoned as hopeless.

9. The operator must be one well skilled in the use of the *x*-ray apparatus.

10. After the suspension of treatment, carcinomata show a strong disposition to return quickly.

4. **Splenic Anemia.**—After reporting a case, Benedict suggests the probability of the occasional relations of hepatic sclerosis to splenic anemia.

12 The Use of Normal Salt Solution. Harry F. Thompson.

6.—This article is noticed in the Therapeutic Department.

7.—Ibid.

8. **Tuberculosis.**—The form here described by Beggs under the title of chronic parenchymatous pulmonary tuberculosis, consists in a general inflammation of the lung substance. The designation he considers is not satisfactory. We might call it pan-pulmonary tuberculosis, but there are objections. In all forms the parenchyma is involved and in the present form all the pulmonary structures are equally affected. He thinks the type is worthy of attention and recognition for the following reasons:

1. It is a perfectly characteristic type of pulmonary tuberculosis, distinctly different from those generally recognized. 2. It is constant in its progress and bad in its prognosis. It is scarcely less fatal than phthisis florida though its duration is longer. 3. It is very insidious, and this tends to cause error on the part of the physician and a mistaken sense of security to both patient and medical adviser. 4. The preceding two reasons render its early recognition of great importance to both physician and patient.

9. **Spinal Concussion.**—Norbury reviews the conditions and concludes that the underlying lesion, as far as the cord is concerned, is a disturbance of the circulation and injury to the blood vessels. Intramedullary hemorrhage, he thinks, is the result. It is impossible to eliminate the psychic element altogether, but pathologically, while more or less speculative, there is a leaning toward the injury theory.

13 On Volumetric Testing for Sugar. John Marshall and Leon A. Ryan.
14 *A Contribution to the Study of Manubrial Dulness, Especially as Related to Enlarged Bronchial Glands. H. B. Whitney.
15 *A Study of Weights in Pulmonary Tuberculosis. Lawrason Brown.
16 Wounds of the Thorax. Isaac R. Trimble.
17 Transient Unilateral Ophthalmoplegia Exterior of Peripherical Origin with Atrophy of the Optic Nerve. Charles J. Kipp.
18 *Glycosuria Gravidarum. William Ruoff.
19 The Bureau of Government Laboratories for the Philippine Islands: Scientific Positions Under It, Etc. Richard P. Strong.

14. **Manubrial Dulness.**—Whitney reports cases with illustrations showing the areas of manubrial dulness in connection with enlargement of the bronchial glands. In all the cases the chief enlargement was toward the left side, contrary to the dulness of aneurism, which is generally on the right. Pressure symptoms may be very pronounced and the value of this little point is considerable.

15. **Tuberculosis.**—Brown has studies the weight variations in tuberculosis and concludes that the decrease is due to toxic absorption. It is not the amount eaten but the amount assimilated that is of value to the consumptive. Carefully regulated rest and exercise are of most importance as regards the bodily weight in pulmonary tuberculosis. Forced exercise should be avoided; change of residence or climate may aid in assimilation. An excessive gain in weight may be a bad sign. The gain in weight is usually first evident on the chest, next on the abdomen in men and the hips in women. A constant rapid loss of weight indicates as much as any other phenomena that the patient is losing ground, while the gain of a few pounds is of little value in the prognosis, but if the gain is continuous over a period of two or three months, the patient is probably improving. A gain of weight is no sure sign of betterment, but on the whole the patients who gain over twenty pounds do better than those who do not. Sunshine and dryness are not necessary factors to gain in weight; cold weather stimulates assimilation and gain in weight more than warm weather.

18. **Glycosuria Gravidarum.**—This condition is studied by Ruoff, who reviews the cases he has collected from the literature and reports his personal observations. He sees no special difference between glycosuria in the pregnant woman and that in other conditions. It may develop during pregnancy or pregnancy may occur after the establishment of the disease, and in the latter event its malignant character is soon established. The infants usually die early. The conclusions are given as follows:

Glycosuria gravidarum may arise at any stage of pregnancy. It is not so serious as when diabetes antedates pregnancy.

It may disappear in one pregnancy and reappear in another, and end fatally after successive attacks. It frequently arises during parturition, but is of no great importance.

Labor is not materially affected, other conditions being equal.

Pregnancy is most likely to be interrupted.

Is very destructive to the fetus. More so than syphilis.

Maternal mortality is nearly 50 per cent.

Diabetics should not marry.

Death is usually by coma, no case of eclampsia having ever occurred in a diabetic.

Medical Record, New York.

20 *Observations on Some Limitations of Diagnosis. Edward G. Janeway.
21 *The Toxicity of Appendicitis, with a Report of Two Cases of "Appendicular Vomito Negro." George R. Fowler.
22 *Cardioptosis and Its Association with Floating Liver. Max Einhorn.
23 *The Pathogenesis of Diabetes. Henry S. Stark.
24 A Case of Acute Dilatation of the Right Side of the Heart. P. P. M. Jorgensen.
25 Tumor Complicating Labor. George W. Squires.

20. **Limitations of Diagnosis.**—Janeway calls attention to the possibility of errors in diagnosis, and especially to the importance of study of the history and antecedents. This is practically illustrated in contagious diseases. He mentions variola, a type resembling varicella and the confusion that has taken place, and also purpuric forms. He gives instances of the difficulties of investigation of typhus and typhoid, and the importance of the diagnosis of gastric ulcers and growths, the confusion between general syphilis and tuberculosis in certain cases, between the various forms of heart disease, etc., all illustrating the limitations of diagnosis and the necessity of a careful study of the histories and antecedents.

21. **Appendicitis.**—The toxicity or toxic effects of appendicitis on the organism are especially noted by Fowler, who particularly calls attention to the complication of vomiting of blood which Kirmisson seems to have been the first to observe. It has also been noticed by Nitzsche, Dieulafoy, and the author, who reports two cases of his own observation. He thinks the occurrence of hematemesis adds another to the already long list of the grave complications of appendicitis. In one of his own cases emboli of the gastric mucosa were found, which fact did not agree with Nitzsche's findings.

22. **Cardioptosis.**—Einhorn first reviews the literature of cardioptosis and then describes the symptoms, reporting cases. He finds that emaciation, enteroptosis and neurasthenia all seem to play an important part in its etiology, but are not alone sufficient to cause it. It is less likely to occur in women, which fact he attributes to their habit of wearing corsets, which serve as a preventive. The chief symptoms are palpitation, brachycardia, tachycardia, etc., and occasional in-

ability to lie on the left side, none of which are absolutely characteristic of this condition. In nearly one-half the cases general enteroptosis is found. It does not endanger life and its subjective symptoms may be alleviated or removed. The main hopes of treatment are improvement of nutrition and strengthening of the nervous system. He also advises avoidance of the stooping position, and sleeping with the head and thorax as nearly horizontal as possible. Direct supports are hardly indicated, though he mentions the possibility of their being of some little use.

23. **Diabetes.**—Reviewing the theories of diabetes, Stark concludes with the following statements:

1. The exact truth of the pathology of diabetes is not known. 2. There are no acknowledged and constant, anatomic appearances of liver or pancreas associated with diabetes. 3. There are no characteristic lesions in any other organ. 4. An impairment of the physiologic functions of the ductless glands may be at the root of the disease. 5. Artificial glycosuria is not diabetes. The facility with which this phenomenon can be elicited, implies its insignificance as a pathologic factor. 6. As far as can be ascertained from competent sources, there is hope that the vacuum in our knowledge of the nature of diabetes will soon be filled.

30 Pregnancy in a Uterus Bicornis Simulating Extra-uterine Pregnancy. Frank A. Higgins.

26. **The Bactericidal Action of Corrosive Sublimate.**—Harrington and Walker have experimented on bacteria with solutions of corrosive sublimate, 1 to 1,000, 1 to 5,000, and 1 to 10,000. The authors find that the different species and different cultures of the same species vary considerably in their resistance to corrosive sublimate. In some species the resistance is markedly diminished by dryness, so that even the 1 to 10,000 solutions can destroy the germs in a short time. Some species, however, are not materially affected by dryness, thus the typhoid bacilli is much more resistant when dry than the diphtheria germ. Corrosive sublimate in as weak a solution as 1 to 5,000 is ineffective against the common pathogenic bacteria, including the pus organisms, when they are moist, excepting after prolonged contact. Since fifteen minutes' contact is not sufficient for the destruction of the *B. coli communis*, *B. pyocyaneus* and *Staphylococcus pyogenes aureus*, whether moist or dry, the use of this and of weaker preparations in surgical work and for irrigation and similar purposes should be abandoned. The 1 to 1,000 solution of corrosive sublimate is very slow in its action on some of the commonest of the skin bacteria, and since under the most favorable conditions more than ten minutes' contact may be necessary for it to kill *Staphylococcus pyogenes albus*, it should not be relied on to any great extent to ensure sterility of the hands or of instruments. The mere dipping of the hands for a few seconds into solutions of this strength can serve no useful purpose, but may lead to a false sense of security. Absolute dryness of the bacteria would be essential for the method to be effective, but this can not be insured. In any of the strengths commonly used it is a much overrated disinfectant and under the best conditions is so uncertain in its action that it would be of advantage to abandon its use altogether in surgery.

27. **Epilepsy.**—Eighteen cases of epilepsy from the Craig Colony, 7 of which died during status epilepticus, were examined microscopically as to the changes in the cortical cells and are reported by Clark and Prout. For comparative study, sections of normal brain were also used. The special conditions found in the cortical cells, especially in those of the second layer and other cells of that type, were striking and differed only in degree in the different cases. The cells were swollen, with chromatic substance almost entirely gone. The nucleus was often swollen out of proportion and ill-defined. The nucleus itself presented a finely granular appearance, and in many cases the nucleolus was dislocated in the process of section cutting. This artefact is much more frequent in these cases than in normal brains. The authors think these facts point to a destruction and ultimate disappearance of the cell as a unit in the cerebral cortex. They do not claim that this represents the final pathology of epilepsy, but the conditions indicate cell death, and teach us something as to the manner of its occurrence. The constancy of the lesion warrants the general conclusion as to the significance of the epilepsy lesion. Epilepsy they say must be considered a sensory phenomenon with motor manifestations. This is also supported by the fact of the action of the bromids, which appear to be effective on the sensory type of cells of the cortex. The anatomic and physiologic integrity of the large motor cells in the cerebral cortex shows the autonomy of these elements. They draw deductions as to the treatment and further study of the disorder from these facts. We should endeavor to exclude toxic agencies, overcome hereditary tendencies, by regulating the diet, exercise, etc., and using the bromids.

31 The American Italy. Charles E. Nammack.
32 *The Kidney of Pregnancy. John O. Polak.
33 *Report of a Case of Infection by the Bacillus Coli Communis. A. Jacoby.
34 *The Surgical Treatment of Empyema. Frank McMorrow.
35 *Fatal Meningitis with Myosis and Salivary Suppression as the Only Symptoms—Autopsy—A Study in Diagnosis by Exclusion. H. Altshul.
36 Sarcoma of the Femur Following Traumatism: Amputation at the Hip-Joint by Wyeth's Method. George S. Brown.
37 *The Surgical Treatment of Ascites of Hepatic Cirrhosis, with Report of a Case. L. W. Pearson.
38 Operation in a Case of Extradural Hemorrhage the Result of Whooping Cough. George S. Brown.

32. **The Kidney of Pregnancy.**—This kidney, according to Polak, is one in which there are no inflammatory changes, but which presents a fatty infiltration of epithelial cells lining the uriniferous tubules, with anemia of the organ. The more recent opinion in regard to the changes is that they are due to imperfect metabolism and a sort of autointoxication. The indications of albumin in the urine as regards prognosis, etc., are noted. It may occur with pregnancy in the healthy woman, and is known to be present in about one-third of the cases of labor. The kidney of pregnancy in the latter part of the period is often to a certain degree pathologic, especially with primiparæ. There is liable to be more or less edema of the legs, but the condition returns to the normal immediately after delivery. The transition from the normal to the pathologic one is, however, very insidious and gradual, often culminating in eclampsia, which the author considers due to a combined toxemia produced by defective elimination from all the emunctories, but particularly the intestinal tract. When the preeclamptic state is recognized by urinary examination and the toxic symptoms like headache, neuralgia, nausea, edema, etc., the amount of nitrogenous food should be reduced and the absorption of toxic materials in the intestines and the tissues of the body be prevented and their elimination assisted by the bowel, liver, kidneys, skin and lungs. If absolutely necessary, remove the source of fetal metabolism and irritation by emptying the uterus.

33. **Infection by the Bacillus Coli Communis.**—Jacoby reports a case resembling typhoid fever, with the negative Widal reaction and the presence of *Bacillus coli communis* in large numbers in the urine. The autopsy showed no inflammatory condition of Peyer's patches, but a general congestion of the ileum and jejunum mucosa.

34. **Empyema.**—McMorrow emphasizes the importance of free opening in the pleural cavity in cases of empyema so that there can be no chance for retention of irrigated fluid or putrid secretions.

35. **Meningitis.**—From a study of his case, Altshul concludes:

1. That extensive meningitis can exist without giving rise to its characteristic and usual symptoms.
2. That sepsis does not always cause changes in pulse and temperature, and that their being normal does not warrant our excluding this condition.
3. That a spasmodic and complete occlusion of the ureter, which is not due to impaction of renal calculi, may last for some time and thus prevent the detection of extensive pyonephrosis.
4. That myosis and salivary suppression may be the first symptoms of meningitis or myelitis.

37. **The Talma-Morison Operation.**—Pearson reports a case and discusses the value of the Talma operation. He admits that it will often cure ascites, but some of the patients will nevertheless die of hepatic cirrhosis. It is often employed too late to be a fair test of the value of the operation. He thinks that a certain percentage of cases may be permanently benefited and hopes that future experience will be more cheering than that of the past.

St. Louis Medical Review.

49 A Report of Typhoid Fever Cases. Charles B. Ford.
50 The Behavior of the Iris in General Diseases. Hamilton Stillson.
51 *Post-Operative Hematemesis. Kenelm Winslow.

44. **Uretero-Cystostomy.**—Smith's article is a report of the experimental studies of anastomosis of the bladder and ureter under tension. He finds that by the use of an oblique anastomosis the ureter and the bladder may be united whenever they can be approximated in spite of tension. Nephritis and atrophy of the kidney on the side operated on may be a consequence, but this condition may follow any operation for ureterocystostomy.

45. **Beri-Beri.**—Bailey's article is an interesting clinical study of beri-beri as observed among the Japanese in a small settlement on Vancouver Island. His observations seem to favor the dietetic origin of the disease, a too exclusive diet of rice being conducive to the condition.

47. **Appendicular Dyspepsia.**—The dyspepsia preceding many cases of appendicitis is considered by Eagleson as not an etiologic factor, but, as a rule, the result of irritation around the appendix. He supports this view by various quotations as to the pathologic process and his own personal experience. From his study he concludes that there is a form of dyspepsia of appendicular origin, largely reflex in one class of cases, depending on the presence of a fecal concretion within the organ, or a slight ulceration or catarrhal condition of its mucosa. In another class of cases it is mechanically caused by an obstruction or irritation resulting from adhesions following a more or less acute attack of inflammation at some previous time. Such cases are suitable for surgical treatment. In case of chronic dyspepsia the condition of the appendix should be studied. When the disease has resisted all medicinal treatment and its origin has been diagnosed as appendicular, an operation should be advised.

51. **Post-Operative Hematemesis.**—Winslow reports a case occurring in his own practice. No lesion of mucous membrane was discovered on careful search. He is disinclined to accept the explanation of sepsis as the origin as offered by Rodman.

62 *On the Duplicity of the Accessory Sinuses of the Nose. G. Bruehl.
63 *Are There "Variations in the Course of the Facial Nerve Having Bearing upon the Mastoid Operation?" B. Alex. Randall.

53. **Pathology of the Internal Ear.**—Manasse reports two cases, one of multiple disseminated gray degeneration of the auditory nerve in a tuberculous patient in which the perceiving apparatus of hearing was specially involved. The anatomic changes in the internal ear in no way resembled other tuberculous processes and were very questionably tubercular. In the other case similar disturbance of the perceiving organs of hearing was observed in a syphilitic patient, but the process in the ear was also a specific one.

55. **Packing in Radical Operations.**—Von Zur Muehlen has lately modified the after-treatment of his radical mastoid operations by leaving out the packing after the first or second dressing, and he finds a decided advantage in this. The procedure of packing is often painful and difficult, especially in children, and leaving out the packing in a certain number of cases seems to shorten the length of treatment. The cavities left at the time of operation filled in with newly-formed tissue appear smaller and less deep, and, consequently are easier to oversee and keep clean. The anatomic relations under favorable conditions resemble the normal. He removes only as much of the bone as is necessary to expose the diseased bone, making the cavity as small as possible. The first tampon of iodoform gauze remains as usual for six days, the second one, introduced much more loosely, remains only two or three, eight days being sufficient to fixate the flap. As soon as this is accomplished he leaves off packing. If subsequent packing seems desirable he introduces it as loosely as possible and dispenses with it as soon as he can. The wound is dressed every day and the area irrigated with warm water, and in case of fetid discharge 10 per cent. naphthalin solution is of use.

57. **Otitis Media.**—Wolff has observed the simultaneous occurrence of otitis media in several members of the same family and follows Lermoyez in considering the condition a contagious one.

60. **The Masto-Squamosal Suture.**—From a study of a large number of skulls Aderman finds that the masto-squamosal suture is distinctly more frequent than is held by Kieselbach and Kirchner, who had previously investigated the subject. He examined 2,554 skulls. In 1,413 of unknown age, 219 presented distinct sutures on both sides; in 54 the suture was distinct on one side and a trace on the other; and in 7 it was unilateral. He has not been able to find any particular racial difference as to the frequency of the suture with the exception of the negro skull, in which it seems to be less frequent than in others.

62. **Duplicity of the Accessory Sinuses.**—Bruehl finds that the double cavity is frequently encountered in frontal and sphenoidal sinuses, but rarely in the maxillary antrum. Anatomic investigation shows that in most cases this is due

to the ethmoidal cells which have extended to the frontal bone, the sphenoid bone and the superior maxillary. A true duplication of the accessory sinus due to a division of the rudimentary condition is extremely rare.

63. The Facial Nerve.—The danger of encountering the facial nerve in operations on the carious middle-ear has been noticed by various authors, and special stress laid on the variability of the course of the facial canal. Randall has studied this subject and finds that the variance is far less frequent and extensive than has been claimed, and that the descending course of the facial nerve to its stylo-mastoid exit is in all the cases studied almost exactly vertical and crosses the oblique plane of the drumhead some 3 mm. back of the middle of the posterior margin of the annulus. Therefore, in removing the back wall of the meatus we should aim to cut a little below the tympano-mastoid suture if we are to keep in safe territory.

64 *What Is Eclampsia? Samuel W. Bandler.
65 *Utero-vaginal Tamponade: Its Obstetric Uses. Joseph B. De Lee.
66 *Primary Carcinoma of the Urethra in the Female. J. F. Percy.
67 *Constipation as an Etiological Factor in Eclampsia. John Aspell.
68 *A Plea for "Bloodless" Surgery in Gynecology. O. B. Will.

64. Eclampsia.—Bandler emphasizes the importance of internal secretions of the ovary and placenta as a pathologic element in eclampsia. A lack of proper control of the placental secretion by the ovarian, and malsecretion on the part of the placental gland, or preferably, a relative malsecretion due to insufficient or abnormal modification of the placental secretion by the elements furnished by the ovaries, furnishes, he thinks, the most plausible and logical explanation of the lesions of eclampsia.

65. Utero-Vaginal Tamponade.—The utility and disadvantages of this procedure are discussed by De Lee, who finds it especially useful in the stoppage of hemorrhage, especially postpartum, after operative procedures; and in cases of cesarean section it may be necessary to tampon the uterus because of atony. He advises the use of a single piece of gauze on account of facilitating removal, and removing it in 16 to 36 hours. It stimulates the uterus to contract, tampons directly the site of the hemorrhage, favors clotting of blood in its meshes, fills up an empty uterus and lifts up and supports the uterus, relieving it of congestion. He is willing to admit that it sometimes has disadvantages, and sometimes women are tamponed that could get along without it. In fact, perhaps this is true of many of his own cases, but what one considers necessary to do in cases of postpartum hemorrhage depends on the standard of obstetrics practiced. The present obstetrical standard is not attempting to save the woman's life, and most of the babies; we must save all the women and the babies that are healthy, and secure them against bad consequences. He has seen the effects of hemorrhage last for months and years, and the loss of over a pint of blood at labor should be prevented. He has found but little use for the measure in placenta previa, excepting where it is necessary to tampon the patient while waiting for help or instruments. It is one of the milder measures to induce labor and is useful in certain cases of abortion. He advises, however, the passing of a thin strip of gauze into the uterus in cases where part of the ovum is expelled and it is impossible to take away the rest, then tampon the vagina tightly with sterile gauze and leave the case until next day. The cervix will then be found soft and easily dilatable, if not fully dilated, and the gauze, with uterine contents, expelled on top of the cotton tampon. As a means of carrying medication to the parturient tract, he considers its usefulness very restricted; indeed, the method is capable of much harm. Constant manipulation of an infected uterus by douches, curettage, medicinal applications, packing, etc., only aggravates things.

66. Carcinoma of the Urethra.—Percy reports a case at length and tabulates a number of others from the literature. From his search and correspondence he has come to the conclusion that cancer of the urethra is as rare as he was at first inclined to believe. He also in this paper calls attention to the more important pathologic conditions that may be confounded with primary cancer of this part, such as syphilitic disease, etc. As regards treatment he says he can repeat that the axiom of free and wide incision holds in the treatment of this condition.

67. Constipation as a Factor in Eclampsia.—Aspell calls attention to this factor in the causation of eclampsia and reports several cases. All the patients were constipated and had had no exercise in the open air for weeks before the attacks. He is, therefore, inclined to look to the liver as being the source of the toxic influence that produces the convulsions.

68. Bloodless Surgery in Gynecology.—Will's article is a plea for massage and manipulation to break up adhesions and reduce displacements, together with the use of pessaries and vaginal tampons to retain them. Other conditions also are amenable to this method. Chronic inflammation, neuralgias, morbid changes in the ovaries, etc., may be favorably affected and subdued by resort to compression, stretching and friction sufficient in degree to produce radical changes in the structure and renewed nervous and vascular activity.

73 *The Age of First Menstruation at Pole and Equator. George J. Engelmann.

69.—The second division of this article appeared in THE JOURNAL, Aug. 9, 1902, p. 302.

71. Suppurating Abdominal Incisions.—In case an abdominal incision for laparotomy suppurates and requires to be re-opened, Darnall would use hydrogen peroxid and formalin and a solution of the newer silver salts or a weak bichlorid of mercury solution until the profuse discharge of pus can be stopped. Then he closes such a wound by slightly anesthetizing the patient, curetting the sides of the incision to freshen up the granulations, placing in the bottom of the wound a narrow strip of iodoform gauze or a few strands of silkworm gut for drainage, and then laying a strip of zinc oxid adhesive plaster about 6 cm. wide in each side of the incision and about 2 cm. from its margin and passing an interrupted suture between the inner edges of the adhesive plaster across the incision without penetrating the skin. An assistant brings the edges of the incision together over the drain by using pressure from each side of the wound. The sutures are now tied tightly across the incision, closely approximating its sides and union takes place promptly, leaving only a straight line scar when the drain is removed.

73. The Age of First Menstruation.—Engelmann has investigated the subject of the appearance of first menstruation and finds it is quite different from the ordinary conception; instead of there being precocious puberty in the tropics and late in the arctic regions, the reverse is often the case. Early puberty is the rule at the arctic region rather than at the equator. The mental factor has much to do with the early development of the function, and he suggests that the carnivorous diet and the habits of the Eskimo may account for their early development, while in the tropics the only possible explanation for the retarded development is perhaps to be found in the torpid nervous system.

74. **Surgery of the Temporal Bone.**—Schmitt's article is an elaborate description of the temporal bone, its anatomy and the surgical technic of the operations involving it.

76. **Toxic Jaundice.**—Anders reports cases which, while not furnishing a basis for definite conclusions, suggest the following queries and propositions:

1. Is there a true polycholia due to the conversion into bile pigment of the hemoglobin that is *suddenly* liberated by certain poisons, as ether, chloroform, and the like, or the toxins of the acute infections, as, for example, lobar pneumonia? 2. Doubtless other causative agents are often operative in cases that fall under 1. 3. As there could be no jaundice without the presence of the liver, the term "hematogenous" is misleading, and should be regarded as obsolete; the term "toxemic jaundice" may be, however, appropriately applied to the cases of "hepatogenous" icterus, in which the blood changes are a more or less striking pathological feature. 4. May not the jaundice rarely seen in secondary syphilis be toxic in nature, at times at least, rather than purely "hepatogenous"? 5. Admitting that there are well-established causes for the hepatic cirrhosis, more particularly of the atrophic form, the etiology is but imperfectly understood. 6. Clear evidence to show that the hepatic cirrhoses are, in many cases at least, of microbic origin is accumulating. 7. The intercurrent acute inflammatory conditions with jaundice in the course of cirrhosis of the liver are doubtless micro-organismal in nature. 8. Relapsing febrile jaundice is also to be classified as an infection; it will probably be shown on further investigation to be due to a member of the colon group. 9. It is probable that the jaundice of hepatic cirrhosis is, in a certain sense at least, toxic in nature.

77. **Typhoid Abscess of the Liver.**—Beginning with a case reported in full, Sheldon discusses the subject of hepatic abscess from typhoid, reviewing the literature and ending with a number of similar cases that have been reported. He finds that the symptoms extend over varying periods. The cases that recovered were undoubtedly the result of pylephlebitis. He can not find a record of a case of hepatic abscess of arterial origin that got well. Prognosis in the cases following typhoid is always grave, and death may be expected in all cases associated with suppurative foci elsewhere in the body. The diagnosis is sometimes easy, but may be difficult or impossible. The treatment is always surgical.

78. **Recurrent Vomiting in Children.**—Edsall discusses this condition and concludes that there is a severe acid intoxication at the time of the attack, not during the interval, of the type seen in diabetes mellitus and occasionally in other conditions. The treatment directed to this acid intoxication is by full dosing with alkalies, which has been in his cases strikingly successful, excepting in one in which the results are still in suspense. He has found in the urine of cases acetone and diacetic acid and notes Marfan's experience, who has also found acetone in the urine in the beginning of the attacks. He disagrees with the latter's theory as to its being due to acetonemia, and considers the cases as confirmatory of his own views. He admits that it is possible that some cases may not have been dependent on the same primary disorder, but it will be an easy matter to determine when this intoxication is present and how frequently flooding the organism with alkalies will prove to be an effectual treatment.

79. **Unilateral Renal Hematuria.**—Eshner reports a case of renal calculus with hematuria in which after the kidney was exposed and found apparently healthy and left undisturbed the symptoms permanently disappeared. He has collected from the literature a number of similar cases and concludes that there are occasional occurrences, in men and women alike, mostly at middle adult life, of hemorrhage from a single kidney—from either with equal frequency, in many instances in consequence of demonstrable organic disorder, and in the remainder of obscure and undetermined origin. This hematuria may cease after simple exposure of the kidney or after nephropexy or nephrotomy, or in the failure of these, after nephrectomy. Since the preparation of his paper he has come across the report of an additional case in which slight mobility of the kidney was accompanied with profuse hematuria.

81. **The Widal Reaction.**—Wolff has modified the Wyatt Johnson method; taking a loop from the feces, smearing it on the agar slant in prepared tube and making one or more bouillon cultures from this specimen. The bouillon must react from 1 to 2 per cent. alkaline with the decinormal acid, using phenol phthalein as an indicator. The infected bouillon is incubated at the usual temperature for twelve hours, when an examination can be made. A sample of blood is taken at the same time a specimen of the feces is procured. This is mixed with the bouillon culture as usual and placed on the microscope stage. If there is sufficient agglutinating material present, the typhoid bacilli, if they exist in the cultures, will shortly form clumps in the field. The rest of the field will be observed full of colon bacilli in active motion. If this same reaction occurs with the patient's own blood we can, of course, safely say that the case has advanced at least to the second stage of the disease. Should no reaction take place, another sample of bouillon culture is tested with blood from advanced cases of typhoid, the agglutinating power of which has been tested by the ordinary method of pure typhoid culture. It is necessary for the proper use of this test to keep in stock a number of specimens of blood from well-marked cases, and if kept in a dry place they retain their effectiveness probably indefinitely. With this blood, if the feces contain any typhoid bacilli, a positive and distinct reaction will shortly occur, while the still motile colon bacilli occupy the rest of the field. This indicates that the case is one of typhoid, and that the disease is in the early stage from the middle to the end of the first week. By this method we can make an early diagnosis and also be able to state that the patient has advanced into the second week of the disease, or beyond the seventh day. He has made a number of tests of this method and has in no case had even a doubtful reaction.

82. **Late Systolic Mitral Murmurs.**—Hall concludes from a study of the subject and of typical cases that in a general way we can explain these murmurs by an asynchronous ventricular contraction.

83. **Malignant Neoplasms.**—Hemmeter has studied the pathogenicity of cancer from the standpoint of the chemist and physiologist. He reviews the various hypotheses and points out the difficulties in the way of the parasitic theory. The paper is largely a report of experimental observations and a number of interesting points and suggestions are thrown out. He admits the possible traumatic origin of adenoma and discusses the effect of the ordinary causes on cell division and the influence of physical laws on cell growth. He believes in intracellular catalyzers and the derangement of intracellular catalysis as a factor in producing malignant growths. In conclusion, he suggests that possibly the blood serum contains defensive substances effective in the destruction of cancer cells, and from this deduces the possible hope for a successful form of treatment.

90 *Responsibility in Active Algophily. J. G. Kiernan.

85. **Nervous Alopecia.**—Coulter reports a case in a child 7 years of age who, subsequent to convulsions, lost her hair from the area behind her ears on both sides. The new growth was irregular, lighter in color, finer and softer to the touch than the normal. The areas were nearly symmetrical on both sides, though extending a little more anteriorly on the left. He considers that in certain conditions the cranio-spinal nerves may have a sudden atrophic influence on the skin and its appendages. The nutritive difficulty, he thinks, was transitory as the hair is approaching more the normal condition. He suggests a blood condition, a toxin formed by a very sudden and severe convulsive stage, manifesting itself in this particular

area because of some special histologic character in the nerve trunk as yet undetected.

90. **Algophily.**—The medicolegal relations of this form of sexual perversion are discussed by Kiernan. He thinks that in many of these cases the responsibility is not destroyed.

97 A Simple Humane Holder for Small Animals Under Experiment. J. Edwin Sweet.
98 Two Cases of Tic Douloureux Treated Hypodermically with Massive Doses of Strychnin. Charles S. Potts.

91. **Accidents from Electric Currents.**—Mills and Weisenburg report a case of apparent bulbar spinal paralysis or myasthenia gravis due to frequently repeated small electrical shocks. There was a late appearing general paralysis of nearly all the musculature, with loss of reflexes. The pathology of the condition is discussed and also the medicolegal bearings of the effects of electric currents of high potential.

94. **Anno Noki or Bushi.**—This substance, the arrow poison of the Ainus of Northern Japan, is described by Reichert, who holds that there is no doubt that it is essentially or solely an inspissated extract of the aconitum frischeri. The experiments which he has made on dogs seem to leave little doubt as to this, as its physiologic action was clearly that of aconite.

95. **Facial Reflexes.**—The reflexes and muscular phenomena in the distribution of the fifth and seventh nerves are reviewed by Weisenburg. The ophthalmic and supraorbital reflex, first mentioned by Overend in 1896 and later by McCarthy, is obtained by striking a light blow with a percussion hammer over the distribution of the supraorbital nerve, the eyes open. A fine fibrillary tremor is first observed in the lower eyelid, and on gradually approaching the tapping to the eyebrows the tremor becomes coarser, the upper lid also being involved and slight approximation produced. This has been found absent in peripheral facial paralysis where the upper branch of the seventh nerve has been involved, and in cases where the Gasserian ganglion has been removed. Weisenburg has found it lacking in superficial facial palsy, but in a large proportion of brain or cord lesions it is normal. The lachrymal reflex may be produced by irritating the nasal mucous membrane, an increased secretion of tears resulting. Care should be taken to avoid a strong light on the eye. This reflex is present in hysterical anesthesia or conjunctivitis, but is diminished where the Gasserian ganglion has been removed. Weisenburg found it diminished in three cases of hemiplegia and hemianesthesia. The cornea mandibular reflex described by von Solder in 1902 is produced by touching the cornea and is shown by a movement of the lower jaw to the side opposite the irritated cornea. The mouth must be partly opened and the lower lid held down for the purpose of observation. The reflex arc is contained in the sensory and motor fibers of the fifth nerve. It is not always present in normal persons, is easily exhausted, but soon restored. Chvostek, in 1876, described the phenomenon named after him, where, as in cases of tetany, by striking over the pes anserinus and in some cases a mere stroking, a spasm of all the muscles of the facial distribution is produced. He thought it was due to a heightening of the mechanical irritability of the facial nerve. It has been found in a variety of conditions, as in hysteria, neurasthenia, epilepsy, tubercular and rachitic conditions, bulbar paralysis, spinal tumors and the late stages of facial paralysis. The malar phenomenon described by Bechterew is the reflex produced by percussion over the malar bone resulting in an upward and backward movement of the corner of the mouth. Weisenburg found this phenomenon not at all constant. The risorius phenomenon is caused by percussion over the angle of the lower jaw, producing retraction of the corner of the mouth backward and slightly downward. The risorius muscle can be distinctly seen contracting. He has observed this in a case of peripheral facial palsy on the affected side, in epilepsy on one side, and in two cases of cerebrospinal syphilis with basal involvement. The last reflex noticed is the depressor labii inferioris phenomenon, caused by percussion over the side of the lower jaw, about an inch and a half back of the symphysis, producing a retraction downward of one side of the lower lip. It is due to irritation of the supramaxillary branch of the lower division of the facial nerve, which supplies the depressor labii inferioris. In some cases, instead of producing a depression of the lip, it produces an upward movement of the same. This is most probably, also, a phase of the Chvostek phenomena.

96. **Formaldehyd.**—Ravenel and Gilliland conclude the report of their experimental study, with the following:

> 1. Formaldehyd gas well deserves the high place which has been accorded it as a germicide. 2. The employment of special apparatus for generation of the gas, while convenient, is not requisite for its successful application, and no one should be discouraged from using it by the lack of such appliances. 3. The germicidal action of formaldehyd gas is largely controlled by certain factors which are, as yet, imperfectly understood. Other things being equal, the most important of these are moisture and temperature. 4. Each operation must be controlled by the exposure of test cultures distributed in every portion of the room to be disinfected, and no operation is to be regarded as successful until all such cultures are proven to have been destroyed.

7 Note of Some Further Experiments Regarding the Nature and Specific Treatment of Hay Fever. Felix Semon.

1. **Gastric Hyperacidity.**—The comparatively recent recognition of the cause of dyspepsia by excess of hydrochloric acid is Russell's subject. In his method of examination he questions the patient as to each symptom throughout the day, with special reference to the time of meals, intervals of relief, time of recurrence of pain or discomfort, etc. He explains the symptoms by the excess of hydrochloric acid digesting the proteid element and leaving the starchy food unaltered as an irritant, keeping up gastric secretion after the normal period of digestion and beyond what can be utilized. He considers this in part due to a special dyscrasia and is willing to admit this among our list of constitutional conditions. The neurotic theory is rejected. He finds this variety common; about 25 per cent. of the dyspeptic cases in the Royal Edinburgh Infirmary came under this category. As regards treatment the correction of constipation may suffice in mild cases. In other cases the use of alkalies taken sometime before food neutralizes any acid residuum facilitating the transformation of the starchy elements, which is in accordance with Pawlow's work on the secretions of the digestive glands. The diet must be regulated by the severity of the symptoms. Proteids ought to be reduced to a physiologic minimum and should be so selected and cooked as to be easy of digestion. The starches should be as much altered as possible, and the quantity of food should not exceed the physiologic requirements.

2. **Enlarged Prostate.**—Thomson favors the suprapubic method, considering the objections as to the danger of extravasation, sepsis and tediousness of recovery as of slight importance. The objections to the perineal route seem to him more weighty; the difficulty in reaching the enlarged organ, the impossibility of making a complete exploration of the bladder, and the danger of missing an encysted or loose calculus. There are cases, however, where operations through the perineum may be advisable, such as cases of extensive adipose development, and in case of small prostate. He calls attention to the predominance of the lateral lobes as obstruction, the fact that the bulk of the prostate is felt in the rectum gives no indication of its intravesical contour and the fact that the size of the prostate has no necessary relation with the severity of the urinary symptoms. While hemorrhage is usually controlled by hot boric solution and does not long continue, it may be advisable to utilize some contrivance to prevent it, and he illustrates a rubber pad, which is introduced through the wound and is attached to a string passed through the urethra by which it can be fitted against the prostatic scar and another string attached to its edge allows of its removal when required. Thomson has no doubt as to the possibility of enucleation in enlarged prostate.

3. **Enlarged Prostate.**—Freyer briefly reports cases and sums up his experience in 31 cases of complete removal within two years in patients varying in age from 58 to 79 years with prostates weighing from 1.5 to 10.25 ounces. A very large proportion of the patients were almost moribund when operated on; scarcely any of them were free from serious complications; 22 of the cases were perfect successes, both immediate and remote, and he means by this complete recovery, the patients being able to retain and pass their urine as well as ever. In no case has there been any relapse, time seems only to consolidate the cures. There were four fatalities, 2 from mania after the operative wound had practically healed and the functions become normal, 1 from heatstroke during convalescence and 1 from coma due to retention of morbid products of the urine in the blood, which had set in before operation. In only one of the four cases could death be attributed to the operation. In all his cases Freyer used the suprapubic method.

5. **Carcinoma.**—Cheatle illustrates cases of rodent ulcer as the most common form of cancer in which secondary deposits in the lymphatic glands are rare and in which the morbid processes are largely confined to certain special nerve areas or branches of the fifth nerve; also cases of squamous epithelioma. He shows that rodent ulcers may be multiple on the two areas of the fifth nerves at the same time; and that they may be multiple on the area of one fifth nerve; and no lesion elsewhere. He notes that cancer belongs to a period of bodily degeneration as a point which is of some importance. He found in one case a degeneration of the posterior ganglion of the spinal nerve supplying the part occupied by the cancer, and this agrees with Lugaro's findings of the effects of peripheral irritation on the effects of the posterior root ganglia. He does not wish to infer that a ganglion degeneration preceded the carcinoma, but can not help alluding to the clinical fact that irritation is a great precursor of cancer, and added to this it causes degeneration in the particular ganglia whose peripheral ramifications

are irritated. Carcinoma often appears in tissues which are associated with disorders of growth, like moles, and these latter are themselves associated with definite nerve areas in the incidence of cancer. He does not want to be taken as offering a new theory of cancer but merely as attempting to show the grounds for considering the possibility that the genesis and spread of cancer may be connected directly or indirectly with the nerve influences, which preside over the areas affected.

6. **Sleeping Sickness.**—The members of the Portugese commission to investigate the cause of sleeping sickness argue for the identity of the streptococcus described by Castellani with their own previously reported type and point out the common characters. While they claim priority they admit the independence of Castellani's work and its importance as a verification of their own.

16 Two Cases of Tubal Gestation with Operation: Recovery. Russell Coombe.

8. **Infective Endocarditis.**—Glynn's second lecture discusses the mode of entrance of the pathogenic organisms. He thinks entrance is often through the lungs and air passages or mouth. The aortic and mitral valves were involved in 21 of his cases, the aortic in 10, the mitral in 15, and the endocardium or the ventricles alone in 1. In a number of his cases there were congenital cardiac defects, stenosis of the pulmonary valves, imperfect ventricular septum, etc. The vegetations in the disease are usually of considerable size and infarcts or emboli occur nearly three times as frequently in the infective cases as in the simple cases of endocarditis, though less commonly in the lungs where suppuration or infarcts rarely occur. This does not mean that the emboli causing these were benign. His classification of endocarditis is according to the severity and the duration of the symptoms: acute, subacute and chronic. The character of the temperature offers some indications of the type and the severity, and more frequently pursues an anomalous course in the protracted forms of the disease. In only a very few were there rigors; fever is often fugitive so that the temperature must be taken often.

9. **Leprosy in the Soudan.**—Tonkin gives the results of study of 220 cases of leprosy in the central Soudan. He finds that the macular variety predominates, while the tubercular type is comparatively infrequent. Males appear to be more subject than females. A very large proportion of cases occur at an early age, from 6 to 20 years, which is not in accordance with observations elsewhere. The primary characteristic lesions were more frequent on the face, the outer surface of the extremities, the scapular region and the buttocks. He has never seen the nodules on the palms or soles of the feet, though the outer borders are often the seat of a dense leprous infiltration. He tabulates the duration of the disease in his cases, which ranges from 1 to 55 years. He has little doubt of the possibility of leprosy undergoing a spontaneous cure. He thinks leprosy seldom lasts more than twenty years in any person. If one lives longer, the disease has terminated. In the post-leprous period there appears to be good general health, though there may be evidences of former trouble in the mutilations, etc. The hereditary element is slight and has very little support from his researches. Very few of the cases observed were descended from leprous parents or grandparents. Leprosy is a disease that itself tends to sterility, the average number of children from leprous husbands and healthy wives was less than one and from both parents leprous not more than one and a fraction per couple. Predisposition is not specific. It often occurs in those that have had no leprous ancestors, and he thinks that deficiencies of diet have much to do with it. Wherever leprosy exists we have certain habits as regards clothing, bedding, etc., and a super-carbohydrate diet which leaves a good deal to be desired. In the Soudan the clothing is rarely washed and handed about freely from person to person. The natives show an utter indifference to the disease.

10. **Nerve Regeneration.**—Henriksen's paper is a full study of the disorders affecting the division of the nerves, showing a regeneration in both the peripheral as well as the central sections. When the nerve is divided it loses its motor conductibility after some little time, and he does not think a certain degree of capability is impossible, for sensory conduction may exist during the whole process of regeneration. The further from the periphery the nerve is hurt the longer time it will take before motor power may be affected and the slower the recovery, but this is not evidence that the nerve is growing out from the central end as held by Vanlair and others. Experiments on animals show that the divided nerve unites equally rapidly whether it is sutured or not, but this does not make it inadvisable to suture as circumstances may take place to prevent union and function. Infection of the wound is of fatal significance, leading to the formation of dense scar tissue and there may be dislocation of the ends of the nerves. If union of the nerve has not occurred or if it is incomplete, examination of sensation shows when interference is required. After about three weeks the tissues at the ends of the nerves are transformed into dense scar tissue which is an obstacle to further development. At the same time a corresponding muscle change will take place and no complete recovery may be expected. It is not absolutely necessary, as shown by experiments, that the ends of the nerves should be at first in absolute contact. The time that may elapse before operation is done without the risk of slow and possibly incomplete recovery may scarcely be estimated at more than about one month. New nerve fibers grow most rapidly the first few weeks, and if union does occur it will be rapidly succeeded by recovery of sensation. If sensation does not return, or if it is incomplete or is proceeding slowly at the time scar tissue has been formed, it means that serious obstacles to the union of the nerve are present and that complete restitution of function can not be expected without operation. Still secondary suture may be performed with good results after a long lapse of time. Jessop reports a case where after the lapse of nine years after division of the ulnar nerve above the wrist, there was still complete anesthesia and paralysis. A secondary suture was performed with the result that sensation returned after eight days, motor power after ten weeks and full restitution after nine months. The important thing in either primary or secondary suture is asepsis. In secondary suture it is important that not only all the scar tissue should be removed, but also that the uppermost part of the end of the nerve should be cut off, the nerve fibers being buried in dense connective tissue.

13. **The Psychic Treatment of Epilepsy.**—The effects of psychic conditions on epilepsy are noticed by Thomson and deductions made as regards the use of psychic stimulus. He quotes from J. W. White's well-known article on the supposedly curative effects of operations *per se* and also from the recent work of Boris Sidis on psychopathic researches in mental dissociation as suggesting the value of the psychic treatment. He also reports the case of a patient which he has carefully studied who has been able by will power not only to ward off attacks, but to retain consciousness of events going on during the partially complete attacks. The author firmly insists on the importance of the early diagnosis of epilepsy so as to prevent the growth of the epileptic habit and the loss of inhibitory power.

17. **Guaiacolated Camphorated Oil in Incipient Infections.**—More than 150 soldiers have been treated by subcutaneous injection of 2 gm. of the mixture described. It proved an excellent measure in the extreme depression accompanying incipient grippe, follicular tonsillitis, bronchitis, etc. The injections display a marked and durable antipyretic action. They are particularly valuable in the army to combat the extreme lassitude observed among the men at certain seasons and among the new recruits. The formula used is guaiacol .1 gm. to .5 gm. camphor and 15 gm. olive oil.

18. **Segregation of Urine.**—Le Dentu states that Luys' segregator has been used now on 45 men and 55 women, and with perfect success. A small model has also proved successful on a boy and a girl. Lambotte of Brussels suggested, in 1890, the idea of such an instrument for intravesical segregation of the urine, but his device for the purpose was not practical, and Luys, without knowledge of it, invented his instrument which has been previously described in these columns, followed seven months later by Cathelin's segregator. The principle is the dividing of the floor of the bladder into two compartments, and thus differs from the instruments devised by Harris and Downes on Neumann's suggestion.

19. **Intraperitoneal Blastomycosis.**—Blanchard's patient was a young mechanic, who had noticed a feeling of oppression in the right side of the abdomen for two months, with constipation and painful indigestion, loss of appetite and considerable emaciation. As he lay on his back, the abdomen above the umbilicus protruded and palpation revealed a fluctuating mass, filling the right half of the abdomen, and especially the iliac fossa. McBurney's point was slightly painful. The skin appeared normal, the veins were not swollen. The presumptive diagnosis was tuberculous peritonitis and appendicitis. The peritoneal cavity and iliac fossa contained a large quantity of a whitish yellow, gelatinous substance in which the appendix and cecum were floating. The former was resected and the jelly removed as thoroughly as possible and the cavity drained. The patient rapidly recuperated and is in perfect health, with no signs of recurrence, more than a year since the intervention. The substance removed was not at all of a neoplastic nature, and the organism had no share in its production except by serous exudation. It consisted of an amorphous fundamental substance containing spherical cells and filaments of a blastomyces pathogenic for laboratory animals, but to date it has not reproduced a jelly pseudotumor like the mass from which it is derived. Strange to say, the organism adapts itself without reaction to the presence and proliferation of this parasite, although the resulting mass compresses and modifies the relations between the elements. There is no zone of irritation, no phagocytosis and no giant cells. This absence of irritation seems to indicate that the blastomyces generates a toxin which paralyzes the leucocytes in the vicinity. The fact of the existence of such a toxin is confirmed by the intense fatty degeneration of the liver and the emaciation of the animals inoculated. The patient himself was also much emaciated. The details of culture growth, etc., are reviewed and the complete illustrated description will soon be published in the "Archives de Parasitologie."

20. **Motais' Operation for Ptosis.**—Since Motais first described, in 1897, his method of treating ptosis by substitution of the superior rectus a large number of ophthalmologists have performed the operation. Some have modified it slightly, but none essentially, and the method can now be considered as firmly established, he states, as the method of operating on strabismus. He shows the physiologic condition and the various points of the intervention in 11 cuts. The movement communicated to the lid by the graft of the superior rectus reproduces exactly the physiologic action of the levator palpebræ. The conditions, therefore, are perfect as regards the esthetic outcome. There is a possibility of two complications, vertical diplopia and ulcer of the cornea. The latter can be avoided and the former is not constant. When it occurred it became gradually attenuated, disappearing completely in fifteen days to five months in all the cases on record. The first step in the operation is to draw the ball down and lid up until the superior cul-de-sac is completely smoothed out and forms a flat surface. The conjunctiva is then incised horizontally about 5 to 6 mm. from the cornea, for a distance of 12 to 15 mm. From the center of this horizontal incision a perpendicular incision is carried upward to the edge of the tarsus. The tendinous expansion of the superior rectus is then exposed through the opening thus made and it is lifted up with a large hook. A buttonhole is cut in the tendon 3 mm. from its insertion in the sclerotic coat, and from this buttonhole two parallel incisions are made for 10 mm. lengthwise of the tendon, thus cutting out of its center a long narrow flap, while not disturbing its attachment to the eyeball. The tip of this flap is held in broad forceps to spread it to its fullest width and a thread is passed through it in a U stitch. The outer surface of the tarsus is then detached from surrounding tissues and the flap is drawn into the recess thus made, the needles on each end of the thread emerging on the outer or inner aspect of the lid as desired. The ends of the thread are tied over a roll of cotton or gauze. The flap is drawn nearer to the edge of the eyelid according as the ptosis is more pronounced. In the 32 operations by this method that have been published, ulcer of the cornea was observed in 5, but this could be attributed in every instance to irritation from the catgut knot of the suture or to direct irritation from the dressing. Motais now uses very soft silk, and has had no irritation in 10 cases in which he has tied the knot of the thread on the inner side of the lid.

23. **Epidemics, etc., in the French Colonies.**—We note, among the items in this official report, that an epidemic of bubonic plague among the natives in the northern part of New Caledonia abruptly ceased after four days of violent rains, "which completely swept the ground." The report states that leprosy is increasing at an alarming rate. During the last twenty-five years entire tribes on this and adjoining islands have been annihilated by it. French Guiana, New Caledonia and points in Oceania are particularly dangerous on this account for Europeans. New cases of leprosy are frequently encountered among French officials returning from these colonies, unconscious that they have been infected. The incessant arrival of these new cases of leprosy is a menace to Paris and the country at large. In New Caledonia a fifth of all deaths is due to tuberculosis. The report comments on the lack of resistance to tuberculosis of the natives of Oceania, notwithstanding their stature and athletic forms. Young men built like a Hercules succumb in a few months to phthisis.

24. **Paget's Disease and Tardy Hereditary Syphilis.**—Fournier replies to Lannelongue's communication asserting the heredosyphilitic nature of Paget's disease. His experience has not been conclusive, but he is inclined to consider it a parasyphilitic affection, like tabes, general paralysis, pigmented syphilid of the neck, leucoplasia and tabic exostosis, which, although largely dependent on syphilis, are yet not influenced by antisypilitic medication. He also discusses the question whether a heredosyphilitic should be informed of his condition, and takes a decided affirmative stand. If young, the parents must be warned, in order that the child may have suitable treatment and that the specific nature of possible lesions may be recognized in time. If the subjects are of riper years, he informs them that they have syphilis, but does not consider it his business to tell them whence they derived it. The source is a secondary matter. The main point for the physician is that the subject has syphilis and must be on his or her guard against its manifestations. The question of marriage for heredosyphilitics imposes the necessity that they should know their condition. He describes several cases to illustrate this point. Robin continued the discussion, reporting some

research on the composition of the bones in syphilitics and in Paget's disease. A syphilitic tibia contains more water and more nitrogenized substances than the Paget tibia, with less fats, while the mineral elements are about the same. The fatty matters in the syphilitic tibias averaged .176, while the Paget tibia showed 13.19, and the other sound tibia of the same subject showed 11.2.

34. **Cocain-Adrenalin Anesthesia of Inflamed Tissues.**—Foisy proclaims that this method of local anesthesia is far superior to all others, as it suppresses both pain and hemorrhage. He has removed with it large carbuncles on the neck and suppurated ganglia in the inguinal region and operated on anal fistulas without pain. He uses a mixture of 20 to 25 c.c. of a 1/200 solution of cocain, with 13 to 15 drops of a 1/1000 solution of adrenalin. In case a smaller amount of a more concentrated solution is preferable, his formula is 1 c.c. of a 1 per cent. solution of cocain with 4 or 5 drops of a 1/1000 solution of adrenalin. The patient reclines and the injection is made along the line of the proposed incision. The needle is then introduced deeper into the tissues, using three or four syringefuls in all of the first mixture. The first prick of the needle is all that the subject perceives. Anesthesia is complete in two or three minutes, but exaggerated pressure or traction on the tissues should be avoided, and the incision must be made through each layer separately. Every vessel oozing even very slightly must be ligated to prevent secondary hemorrhage as the effect of the adrenalin wears off.

36. **Cryoscopy of Milk.**—Parmentier's first communication on the importance and value of cryoscopy as a means of detecting the watering of milk was reviewed in these columns, p. 1032. He gives his experiences in this article and portrays the benefit derived from this simple method of controlling the purity of the milk. In one case two children were suddenly affected with a gastrointestinal trouble traced to the milk, which had a freezing point of .64 C., showing the addition of some foreign substance, found to be an irritating alkali used to clean the cans. In another case an infant was several times affected with enteritis, and the freezing point of the milk was .48 C., which indicated 12.72 per cent. of water. By this means he detected that the milk in certain hospitals was being watered in a proportion of 7, 12, 25 and even 34 per cent., but since the dealers know that the cryoscopy test is being applied the milk has been pure. There is no doubt that many small epidemics among children are caused by impure water being used to adulterate the milk. Some of the crèches were found to be distributing milk containing 12 per cent. water. This may explain many cases of gastroenteritis among infants, and possibly is responsible for the high infantile mortality, especially in summer. He found that the higher-priced milk was as liable to be watered as that sold at ordinary rates. The dealers aim to produce a milk so rich that it supports all the usual tests while still containing a large proportion of water, which hitherto has escaped ready detection. The normal freezing point of normal milk is minus .55 or .56 C. When it is .53 it indicates a proportion of water of 3.63 per cent.; .52 indicates 5.45 per cent.; .51 indicates 7.27; .50 indicates 9.09; .49 indicates 10.90; .48 indicates 12.72; .44 indicates 20 per cent.; .40 indicates 27.27 per cent., and .36 indicates 34.54 per cent. The formula for the calculation is that the water added is equal to the amount of milk multiplied by the quotient of the normal freezing point minus the freezing point observed, divided by the normal freezing point. If the freezing point is above .57 C. foreign substances must have been added, generally sodium borate or bicarbonate.

39. **Tuberculosis from the Social Point of View.**—In this address Landouzy arraigns the armed peace of Europe as one of the most prolific sources of the spread of tuberculosis. He states that during the last eight years alone France has lost 36,000 young soldiers on account of tuberculosis, either by death or dismissal from the service. They may have brought the germs of disease with them into the army, but under more favorable conditions the germs might not have developed. He urges the instruction of girls in the prophylaxis of disease and in hygiene, remarking "that every time a woman is trained a little school is founded." Young mothers thus instructed will guard their babes from intercourse with coughers and from their kisses. They will bring the sun into their homes and abolish dust and dry sweeping. Alcohol makes the bed for tuberculosis. Lancereaux found 1,229 alcoholics among 2,000 consumptives. In the manufacturing centers in the department of the Rhone and of the Seine, tuberculosis claims 255 out of every 1,000 deaths. The proportion of deaths from tuberculosis is 50 per 10,000 inhabitants in the crowded portions of Paris, while it is only 20 in the wealthier parts of the city, as in the Madeleine, and 11 in the Champs Elysées, where the very rich reside. In conclusion, he urges that all the various anti-tuberculosis and anti-alcohol societies, leagues, etc., should be co-ordinated into one grand federation to include every organization working for sanitary and social improvement. Such a combination for the purpose of stamping out tuberculosis, the social evil of our epoch, would be the most exalted expression of the ideas of mutual co-operation and fellowship which ought to govern modern society.

40. **Adrenalin for Cancer.**—Mahu has found that it is possible to arrest the pain and hemorrhage and thus improve the general health, by merely swabbing the ulcerated surface of a cancer with a 1 per 1,000 solution of adrenalin. He describes 3 cases thus treated. It is, of course, only a palliative measure, but in every instance the benefit derived was most remarkable. The neoplasms partially retrogressed and then remained stationary, free from pain or hemorrhage, the patients apparently in robust health. On 4 others the results were nearly as good. The cancers were in the mouth, throat, breast, rectum, or on the face.

Semaine Medicale, Paris.

42 (XXIII, 13.) The Unconsciously Deaf. E. Félix.—Les sourds inconscients.
43 Letter from America (Chicago). La fièvre typhoide aux Etats Unis. F. Münch.
44 (No. 14.) *Valeur pratique de la suture arterielle. F. Lejars.
45 Letter from America (Chicago). La radiothérapie à Chicago. F. Münch.

44. **Suture of Arteries.**—Lejars has found in the literature 23 cases in which an artery was sutured lengthwise, and 4 in which a circular suture was made. The axillary was sutured in 7, the femoral in 6, the popliteal in 3, the common iliac, external iliac, common carotid and internal carotid in 1 each. In a certain number the results were perfect, both immediate and afterward. Even in 7 cases in which the sutures passed through into the lumen, there was no thrombosis or obliteration. This was especially noticeable in experiments on animals, even when a piece of catgut traversed the lumen. Thrombosis is directly connected with infection; when the surroundings were aseptic success was almost invariable. When there is

They confirm those published by Bra, Marchand, von Leyden Blumenthal and others, with organ and serum treatment of cancer.

81. **Stomach-Spleen Reflex.**—Hnatek reports comprehensive experimental study of the phenomenon that the spleen increases in size on chemical, thermic or mechanical irritation of the stomach. He found that the phenomenon occurred after the vagus was severed and that it is a reflex by way of the sympathetic. He also established that it was not due to congestion in the veins of the spleen.

84. **Pathology of the Prostate.**—Remete publishes an account of 2 cases of atrophy of the side of the prostate corresponding to resection of the testicle, twenty-two and nine years before, for trauma or sarcoma of the penis. He proclaims that we can expect atrophy after castration only when the prostate is comparatively normal. After it is once pathologic or degenerated it is no longer capable of a process of involution and, consequently, castration is powerless to effect it.

87. **Improved Roentgen Technic.**—Wiesner makes the exposures through a round hole in the center of a lead-coated board. A metal cylinder is fastened in the hole in the center and can be raised or lowered by a screw. The board is also adjustable on a standard which also carries the vacuum tube above. As the subject reclines, the board is lowered to fit over the part to be radiographed and the metal cylinder is pressed down into the skin, and the radiograph taken through it. By this means only the parallel rays are admitted and no radiation occurs. The pictures are much clearer than those otherwise obtained. It is possible to obtain in this way the most instructive radiograms of the sacrum and spine, even in corpulent persons, in two minutes. The contrivance is illustrated.

93. **Treatment of External Anthrax.**—Graef states that in 62 out of 75 cases of serious external anthrax he was able to transform the threatening lesion into an innocent scab in less than twenty-four hours. Ten of the remainder finally recovered, and 3 died. This percentage of deaths is small in comparison to the statistics published by others, and he attributes his success to his method of treatment. This consists in cauterizing the lesion with caustic potash. He first cuts out the necrotic plug in the center, but carefully refrains from excising into sound tissue, and then uses the caustic pencil.

95. **Sodium Cacodylate in Dermatoses.**—Pabis found this drug effective in improving the general nutrition in cases of eczema, ichthyosis, prurigo and lupus and thus indirectly benefiting the dermatosis.

98. **Gastric Tetany.**—D'Amato reports a case of acute and fatal gastric tetany occurring in a robust man of 32, who for five years had suffered from gastrectasia, the results of stenosis of the pylorus, with hyperchlorhydria. Guinea-pigs were injected with a filtrate of the stomach contents after a test meal, obtained by the stomach pump during the last days of life, as lavage was resorted to as a palliative measure. The 21 animals all died with symptoms closely resembling those of the tetany observed in the patient. The query then arose as to whether the convulsions observed were due to some special toxin in the tetanic stomach or merely to the hyperchlorhydria. Further experiments were made with other animals injected with the filtrate of the stomach contents from a patient with pronounced Reichmann's disease, but no pathologic results were noted in these animals, not the slightest tendency to tetany. He concludes, therefore, that the convulsive toxin found in the stomach of the patient with tetany was a specific, transient toxicity connected with the tetany. The other organs at the autopsy showed also evidences of the action of some toxin.

100. **Lesions of the Cauda Equina and the Radicular Innervation.**—Pansini concludes his extensive monograph on this subject with the statement that everything points to the fact that the terminal peripheral nerve distribution corresponds to the metameres. The plexuses and the peripheral nerves all follow the distribution of the roots, but superposed and intertwined to ensure the multiplicity of innervation of every point at the periphery.

101. **Foschini's Method of Hysteropexy.**—The round ligament is drawn up through a buttonhole on each side, about 3 cm. outside of the inner edge of the rectus. The loop of the ligament is then cut and the two ends sutured to the aponeurosis. He has found this procedure a most effective means of correcting prolapse and retrodisplacement, while it is simple and easy of execution and does not interfere in the least with future pregnancies, as he has several times had occasion to observe. It also holds the adnexa and prevents their displacement, which Pozzi considers as the most important factor in the production of the disturbance accompanying displacement of the uterus.

102. **Nervous Heart Affections.**—Edgren reviews his extensive experience with essential or paroxysmal tachycardia, true angina pectoris and other heart diseases, seeking to formulate a base for differentiation of the merely nervous angina pectoris. The latter he finds occurs usually in younger subjects, although he has exceptionally observed it in persons over 60. The attacks do not follow physical exercise, but are rather relieved by it. They seldom occur at night; are more protracted than true angina pectoris. The subjects complain of their sufferings, throw their arms around, move about restlessly, and appeal to the sympathy of people around. The pains are ascribed to the heart region, but spread around it for quite a distance. In true angina, on the other hand, the pains are more circumscribed and radiate in determined directions, to the left axilla, arm, hand, neck and head. The subject stands immovable and grasps some support, without uttering a word. The oppression in the chest, sensation of constriction around the neck and fear of impending death overshadow the actual pain experienced. The attacks also are brief. In the nervous form periods of tachycardia are liable to alternate with normal heart action. The latter is influenced by slight causes, the physician's examination, change of position, etc., may send the pulse up 20 to 30 beats a minute. A blowing sound is often noted in nervous heart affections, usually systolic, but occasionally diastolic, the maximum over the pulmonic valves. It is brief and

variable. A nervous heart affection may accompany an organic lesion in some other organ. The discovery of other nervous symptoms, neurasthenia or hysteria, will aid in the diagnosis. The objective signs of a nervous heart affection include tachycardia or less frequently bradycardia, "palpitations," a slight degree of arrhythmia, accentuation or reduplication of the heart sounds, and the above-mentioned blowing sound. All these symptoms are variable, some noted at one time and some at another. If constant, they indicate an organic lesion. If the heart is found to be hypertrophied, the case can not be one of purely nervous origin and requires different treatment, as also valvular affections, etc., bearing in mind that it is possible for a mitral stenosis to occur without the usual signs for a time. It is sometimes a difficult matter to exclude sclerotic alterations, especially in case of an old syphilitic, and also slight degrees of cardiac insufficiency. Dyspnea is an important symptom. In nervous heart affections the inciting cause is not physical exercise as in the physiologic and organic pathologic conditions, but is the result of some emotion or nervous disturbance. Treatment should commence with the most careful, repeated physical examination, even when the physician is convinced of the nervous nature of the trouble. The patient should at once be told that the findings are negative and this alone will aid the cure. Therapeutic measures must harmonize with the statement, to ensure the confidence of the patient which prescribing of digitalis, for instance, would have a tendency to undermine. The principal reliance is on dietetic and hygienic measures; a sedentary mode of life must be changed and the fanatic sportsman restrained. Some of the patients suffer from inanition, not from poverty, but from improperly prepared food, irregular meals, etc. Others, on the contrary, indulge too freely in the pleasures of the table. It is important, however, not to attempt to reduce obesity too rapidly or the nervous symptoms may become aggravated to an alarming degree. Treatment of concomitant gastrointestinal or genital affections, chlorosis and anemia is naturally of great importance. Purely medicinal treatment is of subordinate importance. The bromids and other nervines have merely a transient effect. As important adjuvants, mineral waters and baths, gymnastics, massage and, possibly, electricity will be found useful, as also other measures beneficial for neurasthenia.

104. **Operation for Senile Entropion.**—The lids are left untouched and a crescent-shaped piece cut out of the conjunctiva, about as long as the tarsus, and in the middle about as wide or slightly wider than the latter. The wound is then sutured. Ekehorn has successfully performed this operation, the details of which are illustrated, on both eyes of one patient. The entropion dated from about a year previously. The eye appeared normal afterward and showed no traces of having been operated on unless examined closely. Judging from the results in this case recurrence seems to be impossible.

108. **Addison's Disease in Sweden; Carcinoma in Lung, Etc.**—The clinical records and pathologic anatomic findings are described in detail of a successfully diagnosed case of stenosis of the isthmus of the aorta and of 4 cases of primary carcinoma of lung. Josefson also cites 7 cases of Addison's disease that have been published in Sweden and 3 personally observed. One of the latter was distinguished by hyperglobulia. Recent articles on Addison's disease have ignored the contributions of Swedish writers, which now include a total of 10 cases. The age ranged from 24 to 50 and 7 of the patients were men. The autopsy findings are given in his cases.

110. **Incarcerated Obturator Hernia.**—Hellstrom has collected 37 cases of this rare form of hernia and gives the particulars in tabulated form. Death occurred in all but 12. All are from the European literature except Elder's case in the Annals of Surgery, 1900. He describes a case personally observed. The patient was a woman of 67 who had noticed a small tumor for twelve years at the obturator foramen. The hernia was readily reduced at first, but finally caused pains extending down toward the knee and symptoms of incarceration. Complete recovery followed a radical operation by Borelius. In the collected statistics, as in this case, there was a coincidence of some other hernia with the obturator in 4 cases, and in one there was bilateral obturator with bilateral femoral hernia, and in another five hernias at once. The neuralgic pain extending down to the knee was denied in 6 and not mentioned in 8, but was noted in the others. The age ranged from 38 to 84. Sprengel's patient was 80 and recovered after a laparotomy.

111. **"Ether Drunk."**—Sudeck called attention in 1901 to the possibility of operating during the first phase of unconsciousness caused by the fumes of ether. Landström reports that more than 100 operations have been performed at the Stockholm hospital with this anesthesia alone, using merely 10 to 20 c.c. of ether and operating as soon as this has been inhaled in a few deep breaths. In some cases 5 c.c. were sufficient. The operations were mostly short, painful ones, but in one instance a Gritti amputation of the thigh was done, and the patient was kept under the influence of the ether with merely 70 c.c. for thirty-two minutes, giving a few drops the fifth, ninth, eighteenth and twenty-fourth minutes. There is no danger of syncope or unfavorable action on the respiratory organs. Lennander, Ehrlich and von Bruns also report very favorable results with the "Ether Rausch," alone or in combination with local anesthesia, and by repeating it several times in succession have been able to do long operations with it.

113. **To Minimize Dangers from Pregnancy in a Syphilitic.**—Among the measures which Welander advises are the thorough mercurial treatment of the women, preferably by his "pillow case" method. The children should be brought up if possible under medical supervision in a special asylum for three or four years at least. He has organized such an asylum which has accommodations for 10 or 12 children. Eight of the mothers were under treatment at the general hospital before the termination of the pregnancy. None of their children exhibited symptoms of syphilis at birth or since. The other children were marked with hereditary syphilis when admitted to the asylum. All of the children are treated intermittently with the mercurial "pillow-cases." The little asylum has prevented the contagion of others, while it offers the children the very best chances for minimizing their evil inheritance.

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

Practical Points in Nursing. For Nurses in Private Practice. With an Appendix Containing Rules for Feeding the Sick; Recipes for Invalid Food and Beverages; Weights and Measures; Dose List; and a Full Glossary of Medical Terms and Nursing Treatment. By Emily A. M. Stoney, Late Superintendent of the Training School for Nurses, Carney Hospital, South Boston, Mass. Third Edition, Thoroughly Revised. Fully Illustrated, Including 8 Colored and Half-Tone Plates. Cloth. Pp. 458. Price, $1.75 net. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

The Practitioner's Guide. By J. Walter Carr, M.D. (Lond.), F.R.C.P., Physician Royal Free Hospital; T. Pickering Pick, F.R.C.S., Consulting Surgeon, St. George's Hospital and Victorian Hospital for Children; Alban H. G. Doran, F.R.C.S., Surgeon to the Samaritan Free Hospital; Andrew Duncan, M.D., B.S. (Lond.), F.R.C.S., M.R.C.P., Physician Branch Hospital Seamen's Hospital Society. Cloth. Pp. 1107. Price, $6.00. New York, London and Bombay: Longmans, Green & Co. 1902.

Handbook of Climatology. By Dr. Julius Hann, Professor of Cosmical Physics in the University of Vienna. Part I—General Climatology. Translated, with the Author's Permission, from the Second Revised and Enlarged German Edition, with Additional References and Notes, by Robert DeCourcy Ward, Assistant Professor of Climatology in Harvard University. Cloth. Pp. 437. Price, $3.00 net. New York: The Macmillan Co. 1903.

The Care of the Baby. A Manual for Mothers and Nurses, Containing Practical Directions for the Management of Infancy and Childhood in Health and in Disease. By J. P. Crozer Griffith, M.D., Clinical Professor of Diseases of Children in the Hospital of the University of Pennsylvania. Third Edition, Thoroughly Revised. Cloth. Pp. 436. Price, $1.50 net. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

A Text-Book of Legal Medicine and Toxicology. Edited by Frederick Peterson, M.D., Chief of Clinic, Nervous Department of the College of Physicians and Surgeons, New York; and Walter S. Haines, M.D., Professor of Chemistry, Pharmacy, and Toxicology, Rush Medical College, in Affiliation with the University of Chicago. Cloth. Pp. 750. Price, $5.00. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

Medical Jurisprudence, Insanity, and Toxicology. By Henry C. Chapman, M.D., Professor of Institutes of Medicine and Medical Jurisprudence in the Jefferson Medical College, Philadelphia. Third Edition, Thoroughly Revised, Greatly Enlarged, and Entirely Reset.

Fully Illustrated, Including Four Colored Plates. Cloth. Pp. 329. Price, $1.75 net. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

Success in Dental Practice. A Few Suggestions Relative to the Most Approved Methods of Conducting a Practice. By. C. N. Johnson, M.A., L.D.S., D.D.S., Professor of Operative Dentistry in the Chicago College of Dental Surgery. Cloth. Pp. 159. Price, $1.25. Philadelphia and London: J. B. Lippincott Co. 1903.

Tuberculosis: Recast from Lectures Delivered at Rush Medical College, in Affiliation with the University of Chicago. By Norman Bridge, A.M., M.D., Emeritus Professor of Medicine in Rush Medical College. Cloth. Pp. 302. Price, $1.50 net. Philadelphia, New York, London: W. B. Saunders & Co. 1903.

Transactions of the Fourteenth Semi-Annual Meeting of the Medical Society of the Missouri Valley, at Lincoln, Neb., March 20, 1902. Paper. Pp. 47. St. Joseph, Mo.: The Medical Herald. 1902.

Transactions of the Luzerne County Medical Society, for the Year Ending December 31, 1902. Volume X. Paper. Pp. 162. Wilkesbarre, Pa.: The E. B. Yordy Co. 1903.

Twenty-first Annual Report of the Board of Health of the City of Lowell, for the Year 1902. Paper. Pp. 67. Lowell, Mass.: Courier-Citizen Co. 1903.

The Public Service.

Army Changes.

Movements of officers of the Medical Department, U. S. A., under orders from the Adjutant-General's Office, Washington, D. C., from April 10 to 17, 1903:

Devereux, John R., first lieut. and asst.-surgeon, is directed to proceed to Fort Snelling, Minn., for duty, instead of Fort Columbus, as heretofore ordered.

Gilchrist, Harry L., first lieut. and asst.-surgeon, will proceed to Philadelphia, Pa., and New York City on business pertaining to the medical department of the Army.

Kennedy, James M., captain and asst.-surgeon, having completed the duty for which he was ordered to Washington, D. C., will, on the expiration of his present leave, proceed to Allentown, Pa., New York City, Boston, West Point, N. Y., Buffalo, N. Y., Cleveland, Ohio, Chicago and St. Louis, on business pertaining to the medical department of the Army, and on the completion of this duty will rejoin his proper station at the Presidio.

Miller, Edward W., contract surgeon, will report to the commanding officer, 14th battalion, field artillery, in camp at the Presidio, for duty therewith en route to Fort Sheridan, and on the completion of this duty, will proceed to his home, Chicago, for annulment of contract.

The following named medical officers are detailed to represent the medical department of the Army at the annual meeting of the American Medical Association to be held in New Orleans, from May 5 to 8, 1903: Major Louis A. LaGarde, surgeon; Major Charles F. Mason, surgeon; First Lieut. James Carroll, asst.-surgeon.

The following named officers are detailed to represent the medical department of the Army at the Interstate National Guard Association, to be held at Columbus, Ohio, May 4 to 6, 1903: Captain Merritte W. Ireland, asst.-surgeon, Captain Frederick P. Reynolds, asst.-surgeon.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ending April 25:

Medical Director T. H. Streets, detached from the Naval Laboratory, New York, and to duty at the Naval Hospital, Philadelphia.

Medical Inspector G. R. H. Harmon, ordered to the Naval Laboratory, New York.

Asst.-Surgeon J. Stepp, ordered to the Naval Hospital, Portsmouth, N. H.

Medical Director J. B. Parker, detached from the Naval Hospital, Philadelphia, and ordered home to wait orders.

P. A. Surgeon H. H. Haas, detached from the Naval Hospital, Portsmouth, N. H., and granted sick leave for four months.

Surgeon J. D. Gatewood, detached from the *Lancaster* and ordered to the *Yankee*.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended April 23, 1903:

P. A. Surgeon A. C. Smith, leave of absence for 15 days from April 8, 1903, granted by bureau letter of March 25, 1903, amended so that it shall be for 10 days only.

P. A. Surgeon J. A. Nydegger, relieved from duty at Baltimore, and directed to proceed to Gulf Quarantine and assume command of the service at that port.

P. A. Surgeon L. L. Lumsden, to proceed to New Orleans, and report to medical officer in command for duty and assignment to quarters.

P. A. Surgeon J. F. Anderson, to proceed to Great Falls, Mont., for special temporary duty.

Asst.-Surgeon J. W. Kerr, to proceed to Gallipolis, Ohio, and Point Pleasant, W. Va., for special temporary duty.

Asst.-Surgeon T. F. Richardson, to proceed to Bay St. Louis, Pascagoula, Pass Christian, Long Beach, Handsboro, Gulfport, Biloxi, Ocean Springs and Scranton, Miss., for special temporary duty.

Asst.-Surgeon Jos. Goldberger, relieved from duty at Ponce, P. R., and directed to proceed to Vera Cruz, Mex., for duty in office of the U. S. Consul.

Asst.-Surgeon Edward Francis, to report to director of hygienic laboratory for special instructions.

A. A. Surgeon, D. M. Echemendia, granted leave of absence for seven days from April 15, under provisions of Paragraph 210 of the regulations.

A. A. Surgeon John Frick, relieved from duty at Havana, Cuba, and directed to proceed to Tampico, Mex., for duty in office of U. S. Consul.

A. A. Surgeon B. W. Goldsborough, granted leave of absence for 3 days from April 28.

A. A. Surgeon W. C. Mason, granted leave of absence for 3 days from May 5.

A. A. Surgeon M. V. Safford, granted leave of absence for 2 days from April 10, under provisions of Paragraph 210 of the regulations.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended April 25, 1903:

SMALLPOX—UNITED STATES.

Alabama: Mobile, April 11-18, 3 cases.

California: San Francisco, April 5-12, 15 cases.

Colorado: Denver, April 4-11, 28 cases.

Florida: Jacksonville, April 11-18, 1 case.

Illinois: April 11-18, Belleville, 3 cases; Chicago, 17 cases, 2 deaths; Galesburg, 4 cases.

Indiana: April 11-18, Evansville, 3 cases; Indianapolis, 4 cases, 2 deaths.

Kentucky: Covington, Jan. 10-April 18, 98 cases.

Louisiana: New Orleans, April 11-18, 8 cases (imported).

Maryland: Baltimore, April 11-18, 2 cases.

Massachusetts: April 11-18, Fall River, 1 case; Lowell, 2 cases.

Michigan: April 11-18, Detroit, 11 cases; Flint, 1 case; Grand Rapids, 7 cases; Port Huron, 1 case.

Minnesota: Winona, April 11-18, 1 case.

Mississippi: Gulf Port, April 16, 16 cases.

Missouri: St. Louis, April 12-19, 9 cases.

Nebraska: Omaha, April 11-18, 2 cases.

New Hampshire: April 11-18, Manchester, 8 cases; Nashua, 5 cases.

New York: Buffalo, April 11-18, 2 cases, 1 death; New York, April 11-18, 2 cases, 1 death; Rochester, April 14-21, 4 cases.

Ohio: Cincinnati, April 10-17, 15 cases, 1 death; Cleveland, April 11-18, 1 case, 1 death; Dayton, April 11-18, 2 cases; Toledo, April 4-18, 19 cases, 1 death.

Pennsylvania: April 11-18, Altoona, 1 case, 1 death; Johnstown, 1 case; Philadelphia, 10 cases, 1 death; Scranton, 8 cases.

South Carolina: Charleston, April 11-18, 5 cases; Greenville, April 4-11, 1 case.

Tennessee: Memphis, April 11-18, 1 case.

Utah: Salt Lake City, April 11-18, 3 cases.

Washington: Tacoma, April 6-13, 2 cases.

Wisconsin: Milwaukee, April 11-18, 1 case.

SMALLPOX—INSULAR.

Philippines: Manila, March 4-11, 1 case.

SMALLPOX—FOREIGN.

Austria: Prague, March 28-April 4, 8 cases.

Belgium: Brussels, March 28-April 4, 9 deaths.

Brazil: Bahia, March 21-28, 1 death; Rio de Janeiro, March 20-29, 13 deaths.

China: Hong Kong, Feb. 28-March 7, 1 case, 1 death; Shanghai, March 9-16, 12 deaths.

Colombia: Barranquilla, March 22-29, 1 death; Bocas del Toro, to April 6, 21 cases, 3 deaths.

France: Paris, March 28-April 4, 1 death.

Germany: Hamburg, March 28-April 4, 1 case.

Great Britain: Birmingham, March 22-April 4, 25 cases; Dublin, March 29-April 4, 12 cases, 1 death; Leeds, March 29-April 4, 10 cases; Leith, March 29-April 4, 2 cases; Liverpool, to April 4, 62 cases, 6 deaths; London, March 29-April 4, 13 cases; Manchester, March 29-April 4, 24 cases, 1 death; Sheffield, March 21-April 4, 4 cases.

India: Bombay, March 17-24, 85 deaths; Calcutta, March 14-21, 3 deaths; Karachi, March 16-22, 1 case, 1 death.

Italy: Milan, Feb. 1-28, 4 cases; Palermo, March 28-April 4, 1 case.

Japan: Yokohama, March 14-21, 1 case.

Mexico: City of Mexico, March 29-April 5, 8 cases, 6 deaths.

Russia: March 21-28, Moscow, 3 cases, 2 deaths; Warsaw, 7 deaths.

Straits Settlements: Singapore, Feb. 21-March 7, 2 deaths.

Turkey: Alexandretta, March 21-28, 6 cases.

YELLOW FEVER.

Brazil: Rio de Janeiro, March 13-20, 81 deaths.

Colombia: Panama, April 6-13, 3 cases, 1 death.

Costa Rica: Limon, April 10, 2 cases.

Ecuador: Guayaquil, March 21-April 4, 6 deaths.

PLAGUE—INSULAR.

Philippines: Manila, March 4-11, 10 cases, 8 deaths.

PLAGUE—FOREIGN.

China: Hong Kong, March 7-14, 19 cases, 17 deaths.

India: Bombay, March 17-24, 1,270 deaths; *Calcutta, March* 14-21, 751 deaths; Karachi, March 15-22, 120 cases, 97 deaths.

Address.

A PLEA FOR EXPLORATORY OPERATIONS.

AIRMAN'S ADDRESS, DELIVERED BEFORE THE SECTION ON SURGERY AND ANATOMY AT THE FIFTY-FOURTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, AT NEW ORLEANS, MAY 5-8, 1903.

JAMES E. MOORE, M.D.

MINNEAPOLIS.

One duty of the Chairman of this Section, as pre:ribed by our by-laws, is to open the exercises with a rief comment on some surgical topic or topics of live iterest.

During the past year no one subject has been of such aramount interest as to overshadow all the rest, but a teady and even rapid advancement has been made along ld lines, and an exceptional amount of preliminary 'ork or foundation laying has been done along new ines. More time and money have been expended in riginal research than in any previous year. The year as been made memorable by the permanent location in New York of a great laboratory for medical research, which has been placed in the hands of most eminent nen, and from which we have reason to expect reat results. The prevailing sentiment in the surgical vorld is one of wholesome conservative optimism.

Those of us who began the study of medicine before Koch made his immortal discovery of the tubercle bacilus can recall how hopelessly we endeavored to compreiend the term scrofula, that mantle of our ignorance vhich has happily disappeared, and how after this liscovery the clouds began to disappear like snow before he sunshine. Have we not much greater reason, by virtue of our laboratories of research, to hope for the liscovery of the cause of cancer in the near future?

Many of our medical colleges have established laboratories for the instruction of students in operations on animals, and these laboratories are being used more and more each year by practical surgeons in experimental work for the perfection of their technic and for original research. Every surgeon, no matter how much laboratory and experimental work he may have done, or how good a clinician he may be, will frequently meet cases in which conditions obtain within some one of the great cavities of the human body which are endangering the life or comfort of his patient, and which, after having exhausted all ordinary means of diagnosis, he can not diagnosticate. Under these conditions the surgeon should primarily, in the interest of his patient, and, secondarily, in his own interest, perform an exploratory operation. The mere fact that with our aseptic methods we can open the abdomen or the head with impunity gives us no license to make this a means of diagnosis until after all other methods have been exhausted. Nor does the fact that a man has learned to be reasonably certain of his asepsis entitle him to this privilege until after he is thoroughly familiar with both normal and pathologic conditions that he may find. I know of one instance, for example, in which a man opened an abdomen and was then unable to differentiate between the bladder and the sigmoid flexure, yet this patient did not die from sepsis. Such a man has no moral, and should have no legal, right to open an abdomen. This is simply an example of one of the dangers of asepsis.

This humble plea for exploratory operations is made with diffidence, for, "Fools rush in where angels fear to tread," and if this were an accepted method of diagnosis without most rigid restrictions, the ignorant and inexperienced would be the most ready to resort to it.

Owing to the brief time allotted for the reading of this address it will be limited to exploratory abdominal operations.

The term exploratory operation in this paper means a free opening made by the knife. The aspirator and the grooved needle no longer occupy a very prominent place as a means of diagnosis among surgeons, unless it is at the bottom of a wound. It is an open question whether these instruments have done more harm or good. Even the grooved director, which at one time occupied so important a place in a surgeon's armamentarium, has fallen into "innocuous desuetude."

We should no longer be content to divide our cases into operative and non-operative until after we have exercised the same care to form an accurate diagnosis that our colleague, the internist, would, and in addition, in doubtful cases, have made an exploratory incision, for some cases which from external examination would be pronounced inoperable prove on closer inspection to be operable, and in many cases in which a radical operation can not be performed a palliative operation may add somewhat to the patient's life and save him from a great amount of suffering.

It is in the abdomen that the exploratory operation is most frequently indicated, for in this region it is comparatively free from danger, and almost invariably results in some benefit to the patient. It is very rarely, indeed, that a good surgeon will make an exploratory abdominal incision without finding some condition which can be benefited.

At the beginning of abdominal surgery, which is within the recollection of many of those present, most operations were exploratory and were made for conditions in the pelvis, but at the present time, thanks to our accumulated experience and to the fact that in this region we can make bimanual examinations with one a country home away from the influence of smoke. In my opinion the grayish color was due to pathologic pigmentation and not to carbon inhaled. (This is often the case in most of gray sputa, many observers to the contrary notwithstanding.) He had been coughing six months and had lost twenty pounds and had had night sweats several weeks. His temperature had seldom risen above 101 2/5 F. in the afternoons; mornings it had often been subnormal. Being a case of clear tuberculosis, he was placed under the serum therapy as the specific basis of anti-tubercular treatment, and the various special phenomena of his malady were met as they appeared by such measures as were deemed best at the time. Nourishment and out-door air were of course insisted on. Neither creosote, guaiacol or inhalations were used. All these had been employed without good results for six months previously. Creosote and guaiacol seemed to have produced a severe form of dyspepsia, which yielded only to weekly lavage of the stomach. He steadily improved and got well in the course of eighteen months. He has shown no sign of illness for over four years. Infiltration seems to have disappeared absolutely. It would be difficult now, if not impossible, to find any lesion by any form of examination. Indeed, an insurance examiner of experience failed to find anything wrong in his chest.

The most significant features of this case are that it presented the evidence of pure pulmonary tuberculosis; that there never existed in the sputum any of the pathogenic germs that so frequently complicate tuberculosis; that the temperature seldom was higher than 101 2/5 F., and that the case recovered under the natural law measures indicated above, whereas he had been going down grade steadily and rapidly under the influence of the haphazard treatments which had been enforced before. This is one instance of several in my experience tending to show that pure tuberculosis is curable, often with comparative ease, by serum alone, provided such serum has been tested and is really effective. Such a product is not common on the market.

Contrast this case with the next two illustrated, viz.: pictures designated as Case 38 and Case C. The one marked No. 38 presents pus cells, bacilli of tuberculosis very few, and two forms of pus germs—the streptococci and staphylococci, each of them in small number. The sputum which contained these germs was gathered during the existence of an extensive area of more or less dense consolidation and involvement of lymphatic glands. All three of these classes of microbes are poison producers. Five weeks previous the patient had presented unmixed tuberculosis. He in the meantime contracted typhoid fever, and after his recovery from it the pus germs were present. Soon after small vomicæ were found. His temperature arose a few times as high as 103 F. at night, and there appeared occasionally night sweats and chills, but generally the highest point was 101 F. This was when the pus germs were few. The disease gained ground steadily in spite of all possible care, and the remedial measures applied included many remedies approved by authoritative teachers. Classic inhalations, which were begun at the first sign of softening, served seemingly to increase the irritation. Creosote injured the stomach and kidneys. Combined antiseptic and antitubercle sera were used without changing the situation. The strychnin tonics, iodin and sera, combined, and climate had a better effect, causing reinforcements which prolonged life three years. Here we had not higher fever than in pure tuberculosis, except when pus bacteria were numerous, and it was produced doubtless largely by pus toxins, or the mixture of these toxins and tubercular poison, and also by the influence of the lesions and their débris. Did not such complications argue earnestly for discriminate treatment?

Now consider picture of Case C and note all the differences carefully. The picture of its sputum shows pus cells, bacilli of tuberculosis, tetragenii and staphylococci (the latter numerous), each kind of which is capable of producing toxins that may separately, in a measure at least, cause cell, nerve and blood poisoning and fever. What special damage the combined toxins may cause I will not undertake to say. It is sufficient for our purpose to know that this mixed case, with only a very few small tubercular spots scattered in the upper third of one lung, exhibited temperature to 102 F. in the afternoon, coughed and expectorated a good deal of muco-pus with yellowish tinge, and did not do well under antitubercular serum alone. The disease yielded somewhat to a combined treatment, including antitubercle and antipyogenic sera hypodermically with iodin and various forms of judicious inhalations of respiratory sedatives and disinfectants. The patient is patched up, perhaps, only for a limited time. Yet to-day (five years after manifestation of disease) he is living in comparative comfort, without fever, and is working. But there yet remains in him evidence of lesions in quiescent state. These are liable to break down in the future, although with proper care he may retain his improvement.

I now draw your attention to Fig. 4, designated as of "Clinical Records," 1902. It shows sputum containing epithelial cells, few pus cells, tubercle bacilli, pneumococci, and some pyogenic bacteria. This patient exhibited infiltration in the upper half of the front of the right lung, with considerable aching opposite that locality. Fever arose as high as 104 F., but usually wavered between 100 and 103. A confused kind of pneumonia, limited in area, existed, and persisted for three months, after which resolution began and progressed slowly for weeks, leaving the lung impaired in elasticity, but not crepitant. Bronchial râles of a mucous kind were of course often present. Finally the pneumococci disappeared and the pus germs increased. As long as the latter were present in large quantities the temperature ranged from 99 F. in the morning to 102 F. in the afternoon. Later the pus germs decreased considerably, the bacilli of tuberculosis remaining scattered; then the fever wavered between normal and 99 or 100 F. At the time of this writing the temperature was between 97 and 99 F.

As soon as placed under my care this case received treatment applicable in limited pneumonia lesions of this type. It would, I am sure, have been useless to have put such a case under the influence of any therapeutic measure strictly within the line of the routine or specific treatments of consumption. What, for instance, could forced or voluntary inhalation have accomplished? Nothing but harm. The case lives in semi-comfort.

The microscopic display in Fig. 5 is from a case with a cavity four years old. La grippe and hemorrhages had been the first features of the development of the malady. The patient had done poorly most of the time for two years—la grippe recurring three times at least—but for the last year the case has presented comparatively few bacilli of tuberculosis, and this rarely. Cicatricial tissues and membranes seem to be slowly forming in the cavities and the healing process seems to be generally gaining ground. A mixed treatment,

including serum as the chief remedy, the cacodylates and climatology, are constantly in use.

This expectoration shows the existence of staphylococci in small numbers, some zooglea of more minute cocci, which I am not prepared to name, and some bacilli. also of an undesignated character. At one time the bacilli of tuberculosis, different pus and air germs, were numerous, and the temperature then ran as high as 103 F. When this specimen was taken the tubercle bacilli happened to be absent, as they had been for some months, and the temperature did not reach higher than 99 F. In fact, the last year it rarely ran over this point, except during occasional periods of congestion. At present, however, in the morning it sometimes goes down as low as 96 and 95 F. without appreciable discomfort. (Such a depreciation of temperature in the morning is not an uncommon thing in many kinds of tuberculosis.) The patient is now better nourished than at any period of her life, being several pounds above her best weight of her healthiest days. Temperature still wavers between 96 and 98 F.

The sixth picture of the series, Case 44, shows pneumococci and pus cells. The patient had tubercular laryngitis mildly and a large consolidation with pain in the upper third of the left lung. The temperature ranged between 99 and 103 F. Three months before the bacilli of tuberculosis alone had been found. The patient escaped my observation during this period, after which he again presented himself for examination. At this time a congestion of the diseased lung was manifesting itself, the pneumococci appearing in small numbers, as in this cut. In two days, however, they increased enormously. Evidence of congestion and some inflammatory manifestations remained for several weeks. Then a few bacilli of tuberculosis were found. After the pneumonia symptoms had disappeared these bacilli appeared in greater numbers than ever before, but the temperature went down to between 98 and 100 F.

Here is a case of localized pneumonia, complicating consumption, something like in the preceding exhibit, and naturally it suggests also forms of treatment other than those for simple or different forms of mixed tuberculosis. Such measures were instituted, specific and general, to fit the conditions at the proper moment, including special diet, milk, cream, plasmon during sore throat particularly. The patient is now at work, walking miles daily, as an insurance agent, but he is hoarse, though not suffering.

The next picture, known in my records as No. 16, 1900, presents a peculiar mixed infection of tuberculosis. In it are exhibited Friedlander's pneumobacilli, with bacilli of tuberculosis, amid a considerable amount of pus and a few epithelial cells. This case, which died a couple of years ago, suffered at first in the right lung, front and back, from top to bottom, almost complete consolidation. No treatment succeeded in reducing it in the least. Portions of it softened after a while and were expectorated in pieces mixed with pus. About that time the left lung became seriously involved, and finally death resulted. These pneumobacilli remained almost to the last—long after various pus and putrefaction germs had appeared. The temperature never was normal and often went as high as 105 F. It usually wavered between 99 and 103 F.

The eighth figure or case in series 1901 and 1902 is intended to show the finding of the microscope in the sputum of a patient who was suffering from asthma and tuberculosis, with a very limited area of consolidation. The bacilli of tuberculosis and pneumococci were present, and here and there we see Charcot-Leyden crystals and pus cells. As long as the pneumococci remained in large numbers and the infiltration kept prominent the temperature went as high as 103 2/5 F. By degrees resolution took place to a considerable extent, and these germs finally disappeared. The lungs remained impaired, however, and the bacilli of tuberculosis are still present at this writing. But fever with these germs alone does not rise higher than 100 F.

No argument is necessary to show in this case also the need of some circumspect, judicious differentiation in diagnosis and treatment.

Picture 9 (from a patient of Dr. B.) presents a rare combination of débris and bacteria. It includes nasal, bronchial and pharyngeal secretions and excretions with germs. In it we see bacilli of tuberculosis, some fine cocci that do not resemble much, and yet perhaps are, Pfeiffer's influenza (or grippe) bacteria, some long *Leptothrix buccalis* and some epithelial cells. I do not know the history of this case further than was indicated by this presentation, and that la grippe was said to exist in the patient when the sputum was gathered.

I now draw your attention to the tenth picture, designated as AA. In it you will find pus cells, bacilli of tuberculosis and small bacilli of green pus. In this case, analyzed in 1900, there existed scattered areas of consolidation, having respectively, doubtless, a tubercle or more as their nucleus. Patient suffered greatly from bronchorrhea, the matter from which was usually green in the morning. Bacilli of tuberculosis were not always present. Temperature seldom went higher than 99 F. Occasionally it reached 101. He has remained under my observation for nearly three years and is still living, although practically incapacitated for regular manual labor. Remedial measures, including hygiene, nourishment, climate, the cacodylates with iodin used at proper times, and occasionally antitubercle serum, seemed to have served the purpose of holding him in comparatively good condition and free from suffering. There is a decided improvement since 1900.

Fig. 11, designated as Case II, 1899, records bacilli of tuberculosis and other chief characteristics of sputum of a peculiarly offensive kind, which came from a case that fell under my observation in 1899. This patient also suffered from profuse bronchorrhea, but the color of the sputum was brownish and had a very fetid odor. He died with evidences of gangrene a few weeks after my first examination. Every form of supposedly useful treatment, including antiseptic inhalations, had been used without avail before I was called in consultation, and further efforts were not more successful. The patient had used creosote at enormous doses daily for a year without benefit.

The twelfth picture shows germs that I found in the sputum of a case which I examined for a St. Louis physician in 1898. You will notice that the bacilli of tuberculosis are present, some small pus cells and small diplococci and single cocci, with and without surrounding envelopes. (The difference in appearance of these supposedly grippe germs and those seen in Fig. 9 may be due to different staining processes and microscopic amplification.) Temperature 98 4/5 to 102 4/5 F.

The thirteenth picture, No. 12 of records, marked BB, shows the germs found in a patient who died in a sanitarium in 1901. He was not under my care and the history of the case is not at hand. This picture is shown chiefly to present a large germ which I had never found but once before in connection with tuberculosis.

While these thirteen pictures are practically all of different kinds, it will be noted that some pneumonia germs were present in four instances. In my experience of many years the pneumococcus has been present and a common complicator of pulmonary tuberculosis. It is perhaps as frequently found as either of the pus germs that reach the lungs, and sometimes assists in the pathologic processes.

If so many kinds of germs and complications in phthisis indicate anything, they surely indicate the necessity to pay the strictest attention to exact methods of differential diagnosis, whether the cases appear before us early or late, and that we can never be sure that we are applying proper measures without possessing proper knowledge of the pathology of each individual.

I shall now present to you a few pictures of another class, leaving out the bacteria, but showing certain débris and lesions which also have their indications in therapeutics. Two or three of these illustrations are familiar to most of my readers; they have been borrowed in part or in whole or adapted from Peyer and Da Costa.

In the first of these are to be seen the debris found in bronchiectasy. I have seen but one case in which tuberculosis and this bronchial affection clearly coexisted. But the combination is probably more common than this instance would indicate. The material in this expectoration includes pus cells, fatty globules (probably from broken-up leucocytes) and crystals of triple phosphates (irregularly formed) produced by the liberation of ammonia from the nitrogenous compounds in presence of magnesium. Bacilli of tuberculosis in such a mixture are not easily stained, and some other germs, too, are sometimes hard to discover. But the voluminous amount and mixed nature of expectoration in similar conditions should not mystify us or lead us to hasty conclusions eliminating tubercular complications. Prolonged observations, oft-repeated analyses in the course of weeks and months, may be required for proper diagnosis.

Next we come to the elastic fibers, Fig. 15, the significance of which every physician knows. Unfortunately, in sputum analyses they are too often overlooked or neglected. When it is known that they constitute evidence of the destruction of lung tissue, even in early stages of softening, their presence or absence should in all cases, if possible, be established as a guide in prognosis and treatment.

In the third of these, or Fig. 16, is represented a fibrinous cast of bronchi usually existing but rarely expectorated in cases of chronic croupous bronchitis, and very rarely found in connection with tuberculosis. In this particular case, however, the bacilli of tuberculosis had been present in small numbers, but there had been a prior history of chronic bronchial catarrh. At the time the patient came under my observation both sides of the bronchial tree suffered from this condition and dyspnea was very great. Partial infiltration of small areas existed here and there in both and increased slowly. All treatments failed to produce any good results. One day this patient, after using home inhalations of creosote, guaiacol and other antiseptics in glymol, which he had kept up under the advice of another physician for some months, undertook to climb a hill three hundred feet high. On his return he was seized with very serious congestion of both lungs and severe coughing, and died, asphyxiated, in two hours.

Next in order is the consideration of certain important gross lesions in pulmonary tuberculosis. For this purpose I here exhibit an illustration, Fig. 17, showing the essential common features in certain stages of phthisis. With it before us, and bearing in mind the microbiology of tuberculosis, as discussed in this paper, let us endeavor to realize the merits and demerits of various treatments and their effects on the anatomy, the physiology and mechanism of the respiratory organs, as well as, in a measure, on the system generally.

This section of the right lung, trachea and large bronchi shows the following structures and lesions: first, the lower half of the lung appears sound, excepting a cavity (*a*) (although in this half of the lung the tissues may contain concealed small tubercles); second (*b*), the distribution of the large ramifications of the right bronchial tree (down to about the point where the bronchi are about one-sixth of an inch in diameter), penetrating infiltrated and consolidated spots in their course and communicating with the cavity mentioned above; third, a dense and old consolidation (*c*) at the apex, with slight surrounding infiltration; fourth (*d*), tubercle centers scattered in upper third with sound intervening tissue; fifth (*e*), a diffuse, comparatively new infiltration at the side in the middle lobe.

Now, it may be well at this point to refresh our memory about the normal anatomy and physiology of the lungs in order to realize the nature and significance of these lesions and the kind of therapeutics indicated.

Briefly, the lungs consist of a mass of aerial tissue made up of lobules which are "joined together by interlobular cellular membrane, each lobule constituting a distinct lung in miniature, having its own separate vein and artery; that these lobules do not communicate directly with each other;" that their ultimate terminals consist of a collection of microscopic air cells, "alveoli of exceedingly delicate nature, ranging in size from 1/200 of an inch to 1/100 of an inch in diameter," which are in communication with the air by means of filiform bronchioles; that these bronchioles are formed of delicate circular and longitudinal elastic fibers with flattened epithelium up to the point in their outward course, where they reach 1/24 of an inch in diameter; that further out they possess cartilage and a mucous coat, and gradually become larger and denser and stronger as they simplify and progress toward the trachea; that the pulmonary artery accompanies the bronchi branch for branch to the *minutest divisions* (making possible direct medication by means of the blood); "that the circulatory system forms a network of capillary blood vessels of the alveoli where the exchange of the gases (the oxygen of the air and carbonic acid of the system) takes place;" that amid this capillary network of the alveoli, beneath the endothelial layers, there exist lymph spaces which communicate with lymphatic vessels, that get eventually in communication with the air on one hand and the pleura on the other, thus opening innumerable channels for lymphatic and pleuritic infection by microbes inhaled into the lungs.

The important facts I wish chiefly to draw attention to are that the remote divisions of the bronchioles are of microscopic size, therefore invisible to the naked eye; that their infundibula are made up of minute cells of about *1/200 of an inch in diameter, and that the* mass of the lungs consists of inflated, spongy tissue, which these cells and connected structures form, and that the blood vessels permeate them everywhere, assisting in the exchange of carbon for oxygen, and finally, that a system of lymph vessels, glands and interstices involves all the air cells and puts them in communication with the outside air and pleural cavity.

We may add that the bronchi, large and small, and the air cells secrete mucus and that, under irritation, they may form sufficient of it and of certain pathologic material to fill them more or less and obstruct patches of lung enough to prevent sufficient communication with the air; and, furthermore, that by inflammatory processes the plasma of the blood may in part filter through the vessels and cause infiltration of the lung tissue, making it more or less impermeable to the air inspired.

The facts related in the two preceding paragraphs suggest and explain some questions of interest in tubercular pathology and therapeutics. To begin with, the anatomy and physiology of the lymphatic system in the lungs show how nebular intrapulmonary medication is wholly impotent in perhaps all cases involving the necessity of reaching lymphatics, which is so common. The lymphatics do not breathe, therefore the vaporized drugs can not get into them. This anatomy and physiology show also how and why we have so many cases of tubercular pleurisy and so many kinds of secondary tuberculosis in various organs of the system. Diffusion of the disease germs takes place through the lymphatic channels.

In the circulatory system, affecting the spongy tissues so thoroughly, we find, on the other hand, the explanation of the success often obtained in the treatment of tuberculosis by internal or hypodermic medication where direct lung measures fail. More of this farther.

To bring the important question of therapeutics to a focus, I will specify that there are two chief divisions of treatment. First, the aerial division, which includes in part climatology, pure or medicated air, and the artificial efforts to drive remedies directly down into the lungs; second, the circulatory division, which means all the efforts to reach the lungs and influence the system generally by means of the blood and lymph circulation. This includes internal medicine, hypodermic injections and dietetics, either of which can be of service only after absorption of the remedy or food in the system. Both of these divisions have their advocates, both have their usefulness and limitations, and both are abused by those who prescribe mindless of pathology (among whom, by the way, are very widely known men, who seem not to understand analytical work or have it done crudely by inexperienced persons). In the first or aerial division belong numerous, often reckless, usually haphazard forms of inhalations, tracheal injections, sprays and nebula, which in their place and at the proper time have a measure of usefulness. How far can inhalations reach, for instance? Even if the normal anatomy and physiology of the lungs permitted it, it is evident that the consolidations exhibited in the picture of the section of the lung here presented would allow very little or no air to reach the alveoli or to reach properly even the periphery of the lesions, far less the structure of the central portions. By what law, I ask those who commend and apply intrapulmonary medication generally or as a routine practice, can any form of pressure cause medicated air, or any other remedy, to reach the ultimate structure of such diseased tissues and heal them? Is there any way to force nebula into such patches? Decidedly no, and when it is remembered that all tubercles, large or small, are to some extent accompanied by more or less consolidation, which precludes even proper natural respiration, who can not realize the futility of all efforts to force inhalations into them? Yet it is claimed that not only such consolidations *en masse* can be reached by fine nebula, but that the air cells that constitute them can also be medicated by this means under a pressure of thirty, forty or eighty pounds! This claim is so remarkably contrary to known physiologic and pathologic facts that one who reads it or hears of it wonders at the daring of those who advocate it before the intelligent minds of the medical profession. It is wholly incompatible with the laws of physics and physiology. Indeed, while nebulized medicines are really very fine divisions, these are individually visible to the naked eye, and to drive one of them down in an air cell would be practically like forcing a globe the size of a baseball into a receptacle the size of a marble.

It must be remembered, besides, that the air cells are always partly filled with residual air, which can not be forced out, and that these cells can not be unduly dilated without tearing them open. Furthermore, the lungs within and without sustain an average (at our altitude, at least, Asheville, N. C.) of 10 to 12 pounds of pressure. They are maintained in their natural condition of partial expansion by this in and out equilibrium of air pressure. Suppose the pressure within the lungs is increased without compensation on the outside, what law would prevent dilation or rupture? We see, then, that certain kinds of intrapulmonary medication preached to the profession and public are far from always being right and safe. In truth, only three benefits can be derived from the best forms of direct pulmonary medication; that is to say, from tracheal injections and inhalations, to-wit: a limited degree of disinfection of such parts as such treatments may reach; second, a limited palliative influence over such irritated points as they traverse or touch (more or less poorly), and, finally, a limited degree of influence in subjugating cough. In no case is the *indiscriminate* use of such measures and their medicines right, and some conditions sometimes forbid them; for instance, seriously inflamed bronchi and acute congestions. To obtain the results possible by nebular medication, all that is necessary is to have an apparatus capable of forming fine nebula or sprays, such as the Globe Nebulizer or the Robertson and De Vilbiss instruments, and then have the patient inhale proper remedies at their leisure; or a room may be filled with nebula or medicated vapors. High pressure simply makes finer nebula; these, as made, are sent with the full force back of them into the throat, from which the patients breathe in what they can. It does not appear to be good practice to apply 40 to 80 pounds of pressure into the throat of tubercular patients. They have more than enough trouble in keeping their throats from hyperemia and secondary infections without increasing the tendency to these dangerous conditions by unnecessary rough treatment of sensitive and delicate membranes. Evidence showing the correctness of this estimate is not wanting.

I need not dwell on the value of the second division or circulatory medication. It is established beyond controversy that certain drugs in certain forms can be sent through the lungs by means of the blood just as easily as they can be sent to all tissues that receive nourishment. Whoever knows the physiology of the circulation must accept this as a fact. It is true that those lesions which are more or less solid fail to receive blood freely, but even they absorb the essentials of the blood from neighboring sources. Besides, this form of medication, administered hypodermically or otherwise, may be used so as to produce most beneficial effects by direct and indirect influences on the blood, the nerves, the digestive organs, etc., etc.

Having in mind the numerous different kinds of pulmonary tuberculosis, we can not escape the conviction that many forms of treatment now in vogue, besides the mechanical means discussed here, are also useless and some of them dangerous, if not fatal, when applied without respect to the pathologic conditions present at the time, as, for instance, the use of creosote in a reckless manner and the abuse of alcoholics. Nor is full knowledge and realization of tubercular pathology and microbiology sufficient for the best work. It is, moreover, necessary to realize the condition of the digestive, eliminative, circulatory and nervous organs and to apply properly the means necessary to correct whatever fault they may exhibit. Observe, for instance, the sudden rise of temperature from normal to 103, 104 and 105 by indigestion alone, or in connection with absorption of pus, etc.! Such conditions do arise, complicating consumption by addition of auto-intoxication to it. I have seen such occurrences (auto-intoxication from the alimentary canal) arrested by one stomach and one intestinal lavage, which, by the way, is a particularly common necessity for the control of digestion, because indigestion is so common in almost every case of pulmonary phthisis in which ordinary drug measures are not always applicable.

To be specific as far as possible on a general question, what, then, constitute the most reasonable and most promising methods of treatment of tuberculosis pulmonalis, particularly in mixed conditions?

The details are not appropriate here. In fact, I have gone already beyond my first intention on the subject of treatment. But there is reason to indicate the basic elements that need be understood in mixed and simple tuberculosis if one is to pursue a right course and try to cure. In all cases we need first, nourishment, by which I mean the assimilation of proper food supplies, including under this head, for convenience, the breathing of proper air. Without these in sufficient quantity and good quality, no remedy will succeed. With them as foundation, diverse treatments, applicable in different conditions, may be properly selected after understanding each case. Thus the reliable, tested antituberele sera (not the ordinary, untested commercial stuff), the cacodylates, the assimilable and non-irritable iodins, tonics, appetizers, stomach lavage, raw beef juice are useful in probably all cases, provided the proper moments for each or certain combinations of them are not neglected.

No matter what their nature, special complications demand special measures of relief. For instance, pulmonary congestion may be relieved by a hygroscopic plaster; cough by camphor, hyoscyamus, heroin, codein, hydrocyanic acid, etc.; dyspepsia by stomach and intestinal lavage, pepsin, takadiastase, and other dietetics; intestinal auto-intoxication by high colon lavage and intestinal antiseptics; anemia by soluble iron, milk albumin, protonuclein, etc.

I repeat that the most important problem in the treatment of consumption of any kind is that of nourishment. It must be sufficient in every instance or failure is unavoidable. Speaking in a general way, milk, cream, meats, a dozen of whites of eggs in water every day, whole eggs in sherry wine, fish, oysters and appropriate meat juices are among the very best foods. Potatoes and bread are among the most useful of vegetable origin. Unfortunately, in the majority of cases that come to the physicians, there arises the necessity of feeding them, at times, with more highly nutritious and assimilable substances than is afforded by natural products. This is especially common in enfeebled stomachs and sore throats. Thus, in throat tuberculosis, for instance, both local pains and indigestion are usually present. The pain produced by swallowing is so excruciating at times that even water produces torture. In such unfortunates, raw eggs, milk and cream are usually the most easily swallowed natural foods. But they may not always suffice, and often they upset digestion very much. This is often true of sweet milk. I have tried all sorts of artificial nourishments to assist these, or alone in many conditions. I have made numerous trials of many manufactured and home-made products in cases accompanied by poor digestion, assimilation and painful deglutition. Several are pleasant, but few are nourishing enough.

There is one kind of food used by many now which is possessed of special virtue as nourishment and medicine at the same time. It is the fresh juice made daily from raw beef.

Professors Charles Richet and J. Héricourt, both medical experimentalists and teachers of international reputation, presented to the Congress of Medicine in 1900, and afterward to the Academy of Medicine of Paris, many reports on their clinical experiments with such juice in consumption. Since then numerous physicians in every country have verified the claims of these scientists that raw beef juice is not only nutritious to the highest degree, but that it possesses specific curative virtues to arrest the malady. But it must be raw, not heated in the least. Its serum must be unimpaired, for this is internal sero-therapy, so to speak. To get good results large quantities must be given daily—all of the juice of four to six pounds of steak between meals. Strange to say, this does not interfere with the regular meals or the application of a special diet. It will be a pleasant surprise to those who have horror of raw meat to know that this fluid is very palatable and may be made delightful. My experience with raw beef juice in large quantities has been most gratifying, particularly in connection with plasmon, the cacodylates, serum, iodin, etc.

The unfortunate part of this most useful measure is that few presses can extract more than 25 per cent. of the juice from raw meat, thus reducing the chances of its use and making it expensive. I have tried everything in the shape of press I could find on the market, excepting high-priced hydraulic presses, and only the Hayes Meat Crusher have I found to extract more or less easily 75 to 85 per cent. and stand the effects of hard pressing without breaking, but it is in the present size a little expensive. As it is essential, as I have said, to use large quantities of beef juice to get any good results, and, as all that exists in six pounds of good beef is usually necessary every day, it will be seen at once how costly it would be to use presses extracting only 25 or 30 per cent.

In conclusion, I urge the study of the results obtained in France and elsewhere with the cacodylates, reliable sera, iodin and beef juice in consumption.

THE NEW UNITED STATES PHARMACOPEIA.

JOSEPH P. REMINGTON, PH.M., F.C.S.
CHAIRMAN COMMITTEE OF REVISION OF THE U. S. PHARMACOPEIA
PHILADELPHIA.

The numerous inquiries from all parts of the United States with regard to the appearance of the new Pharmacopeia would seem to require at this time a communication as to the progress of the revision, and the writer takes this opportunity of stating that the work is progressing favorably. On account of the death of the distinguished chairman of the Committee of Revision, Dr. Charles Rice, May 13, 1901, revision was necessarily retarded; nevertheless, the subcommittees to whom the details had been assigned have performed a large amount of work. The twenty-six members from all sections of our country, composing the Committee of Revision, were selected by the United States Pharmacopeial Convention in May, 1900, to complete the work of revision, because of their fitness for their work, and necessarily the majority are specialists in the various departments of therapeutics, pharmacognosy, chemistry, botany, analytical chemistry and various other departments which are represented.

ORGANIZATION.

The work of the subcommittees is placed, from time to time, before the general committee by the chairman, in the form of a report, and this report is then voted on; the opportunity being given for each individual member to record his approval or disapproval of any of the details, although naturally much greater weight is given by members to the views and opinions of those who have devoted the greater part of their lives to the special work for which they were selected. Communication between members is mainly by correspondence, and the circular letters and private letters which have been sent out during the last two years number over four thousand.

METHOD BY CORRESPONDENCE.

Prior to the year 1880 pharmacopeia revision was conducted through personal meetings of the members, but in 1880 a different method was inaugurated, the committee was enlarged nearly fourfold and the method by correspondence established. The reasons for making the change were mainly to secure a larger geographical representation and a wider scope, because, as our republic progressed rapidly and the center of population moved westward, it became necessary to recognize the changed conditions and make the book as thoroughly representative of all sectional demands as possible. It can not be said, however, that either of the plans of revision—by correspondence or personal meetings of the committee—are without faults. There are members living to-day who have served the committee under both plans. The method by correspondence loses the value of that individual contact which every one recognizes as so important in revision work. Members are oftentimes loth to vote on certain subjects which are out of their special line, as they would greatly prefer to take the judgment of their colleagues, and a personal conference of the committee of twenty-six would result in the settlement of many questions, after hearing argument, in a much shorter time than would elapse after correspondence among the twenty-six members. But it was foreseen, when the change was made to the method by correspondence, that it would be impracticable to have frequent personal meetings of the committee, not only on account of the great expense involved (for some of the members would have to travel from one to two thousand miles), but as each member of the committee is a busy man it would entail great sacrifice and inconvenience to give up all home engagements and meet often at some distant point.

On the other hand, revision by correspondence has many advantages. It places on each member of the committee a greater sense of responsibility for each vote that he sends in to the chairman. His individual judgment is not swayed by oratory or the superior argumentative abilities of a speaker, and he may take more time to arrive at a correct judgment on the question than would be possible at a personal conference. The committee of 1900 has endeavored to secure the merits of both plans, for those questions which can not be well settled by correspondence are deferred until a personal meeting can be held. An experience of twenty years in revising the Pharmacopeia by correspondence mainly has developed many improvements over the methods first adopted, one of the greatest, undoubtedly, being the stability of organization, now assured through the incorporation of the convention and the separation of the purely business functions from the special work of the revision.

DIVISION OF LABOR.

All of the financial work and the publication of the book is now vested in a board of trustees, while the preparing of the manuscript and the revision proper rest alone with the committee of revision. The board of trustees secures information and the co-operation of the interests of the convention and the committee of revision by making the chairmen of these two bodies members of the board. It will thus be seen that the machinery employed to make a new pharmacopeia is not needlessly complex, and it is believed that all interests are properly guarded and the work of the judicious selection of medicines, the best processes for their preparation and the fixing of fair standards will be duly accomplished.

DIGESTS OF CRITICISMS.

One of the most valuable features connected with the work of revision of the Pharmacopeia of 1880 and 1890 has been the preparation of what are known as "Digests of Criticisms." These are bound books which contain a compilation of all of the criticisms and suggestions on the United States Pharmacopeia, gathered from pharmaceutic journals throughout the world. The criticisms are classified and arranged alphabetically, and are published for the benefit of any one interested in pharmacopeial work. They are furnished freely, without cost, except a trifling one to cover postage, and it is thus possible for any member of the committee to have constantly before him, when studying the preparations, all of the published criticisms that have appeared up to the time of the publication of the digest. It can easily be seen that this most excellent method, which was devised by our late chairman, will prove of the utmost value to the members.

INTERNATIONAL PHARMACOPEIA.

The idea of establishing an international pharmacopeia, which shall be an authority in all civilized countries of the world, has practically been abandoned, after having been under consideration by various international congresses for the last forty years. An international pharmacopeia once reached the stage of the manuscript form, and it was this actual practical demonstration which has had more to do with the abandonment of the idea than any other influence. When, after consultation among European physicians, pharmacists, chemists, botanists and experts, the international list of preparations appeared it was almost universally condemned. The French would not accept it because there were too many German and Austrian preparations found in the book and not enough French; the English would not give it serious consideration because medicines which had been used for generations by them were omitted; and Americans scarcely felt enough interest to inquire about it when they found that American preparations had been completely ignored. And so it must ever be, until the great day of universal peace, harmony and good-will, and when this time is reached probably no pharmacopeia will be needed at all.

An idea has, however, grown out of this long-continued agitation which promises practical results, and this is, for all civilized nations to agree on a uniform strength of what are known as "potent remedies," or as the French term it, "medicaments heroiques," and the International Congress, held in September, 1902, at Brussels, recommended such uniformity. The principal reason for establishing this kind of an international pharmacopeia is to secure uniformity in the dosage of such important medicines as solutions of arsenic and preparations of opium, digitalis, nux vomica, belladonna, etc., so that a patient traveling in any country and having a prescription containing a potent remedy runs little risk of danger on account of the substitution of Fowler's solution made by either a Swiss, German or English pharmacist for the one originally prescribed. For instance, if arsenical preparations were made throughout the world of 1 per cent. strength, all danger from this source would be removed.

It can not be hoped that the new United States Pharmacopeia will please everybody. No pharmacopeia in the world was ever published which was universally accepted by all of the affected interests. Anyone can be convinced of this fact who chooses to consult medical and pharmaceutic literature bearing on the pharmacopeias of the various countries. This is particularly the case with regard to admissions and expurgations. One physician or pharmacist sees in the book some drug or preparations which he has never used and possibly never heard of. Another looks through its pages and does not find his favorite remedy; but it must be remembered that the title of the book is "The Pharmacopeia of the United States of America," and a drug which may not be used in one section is largely used in some other. And again, some preparation which may have considerable local use finds no favor outside of a circumscribed locality, and it would be impossible to think of loading the Pharmacopeia with preparations which have merely a circumscribed use.

Neither can a pharmacopeia be expected to contain all of the new remedies which are exploited by the various manufacturing firms throughout the world. This ever-changing, yet never-to-be-suppressed condition imposes on the revision committee a most difficult task of selection. It can only recognize the newer remedies which have stood the test of sufficient time to demonstrate their value, and of late years the "embarras de richesses" has been so pronounced, and one good new remedy has been so rapidly supplanted by something better (if the advertisements of the manufacturers are credited), that the task of the committee has been greatly increased. Nevertheless, it is believed that the new Pharmacopeia, when it appears, will be abreast of the times and be recognized as fully worthy to stand with any of its predecessors, and contain between its covers a list of medicinal substances with descriptions, tests and formulas for preparing the same, which will be recognized throughout the length and breadth of the land as authoritative.

Music for Insane.—The "Medical Times" says that the authorities of Manhattan Asylum, Ward's Island, are making systematic experiments with the music cure, and have treated a dozen cases of melancholia, giving them concerts an hour long every afternoon with the harp, violin and piano. They report, after a month's trial, that improvement is shown, and that patients suffering from acute mania and hallucinations show more mental alertness and cheerfulness, and that one patient has been assisted almost to recovery by the violin alone.

CASE OF FUNNEL PELVIS WITH CESAREAN SECTION.

CHARLES B. REED, M.D.
Assistant Professor of Obstetrics, Northwestern University Medical School; Associate Obstetrician Chicago Lying-in Hospital; Obstetrician Cook County Hospital.
CHICAGO.

HISTORY.

On May 4, 1900, in my service at the Chicago Lying-in Hospital, I saw the patient, aged 19, in her first confinement. She had been in labor twenty-four hours, the membranes had ruptured and dilatation was complete. The unengaged head presented, mobile above the inlet in L. O. A., and the woman was nearly exhausted by her long labor. The external measurements of the pelvis were small and the conjugata diagonalis could not be obtained. The outlet seemed contracted, but an estimation of the size of the child's head did not apparently preclude its passage and, with the usual preparations and precautions, a combined external and internal version was done. The anterior foot was seized and brought down and the extraction followed directly. No trouble was experienced until the head reached the inlet and refused to enter; under the combined use of pressure from above (on abdomen), the Walcher position and the Smellie-Veit method of delivery, the head slipped through the inlet, passed rapidly and without difficulty through the excavation to the bony outlet, where its progress was stopped. In spite of our utmost efforts the attempts to complete the delivery failed. The child was asphyxiated, craniotomy was done through the roof of the mouth and the mutilated head passed the contracted outlet with some difficulty.

In October, 1901, she reappeared, pregnant for the second time, but with no knowledge of the date of conception. She did not remember when her periods were interrupted, nor when she first felt life.

From examination it seemed probable that labor would occur about Feb. 1, 1902, and, appreciating the difficulties which the case presented, her own and her husband's consent was secured for the performance of any operation which would most nearly promise a living child.

Labor began at 2 a. m., February 16, and 8 a. m. she went to Wesley Hospital and was immediately prepared for cesarean section. No internal examination was made. The operation began three hours later, with the courteous assistance of Dr. Watkins and the resident hospital staff. Through the usual median celiotomy incision the uterus was delivered, the blood supply manually compressed and a median longitudinal incision made in the uterus, through which the child was easily extracted by the anterior foot. Contraction of the uterus was secured by massage and hot applications and the placenta was delivered. The opening in the uterus was closed by through-and-through sutures of chromicized catgut. After direct measurement of the inlet the abdominal wall was closed.

The thoroughly mature male child was cared for by Dr. Farrell and cried lustily. The head was well ossified and nonconfigurable; a small caput was found over the left eye. The child weighed 3,400 grms. (7½ lbs.) and gave the following measurements: Length, 52 cm.; bitem., 7.5 cm.; bipar., 9.75 cm ; occ-front, 12.5 cm.; occ-mental, 13.75 cm.; subocc.-breg., 10.0 cm.; occ-front-circum., 37.0 cm.; subocc. greg. circum., 33.0 cm.

The involution progressed rather slowly and at the time of the removal of the sutures the uterus was found to be adherent to the abdominal wall throughout the entire line of the wound, resulting in an involution which took place laterally, but hardly at all longitudinally—the uterus being long and narrow in form and extending to the umbilicus.

The convalesence was interrupted by a slight pleuritis, but at the end of the fourth week she left the hospital with her babe in excellent condition. Examination about three months later showed the condition practically unchanged.

IDENTIFICATION.

The measurements in this case are very interesting as showing a pure type of the "funnel pelvis" (masculine or infantile pelvis), by which is meant a pelvis with normal or only slightly contracted inlet and high lateral walls which converge strongly downward to a markedly contracted outlet. In the identification of this pelvis it is necessary to exclude certain anomalous pelves wherein the contracted outlet exists only in association with characteristic deformity of the vertebral column, such as kyphosis and spondylolisthesis, as well as those cases of uniform generally contracted pelves wherein there occurs a slight increase of contraction toward the outlet.

The absence of vertebral deformity excludes the first two, and the measurements are so characteristic of the funnel type that the diagnosis can not be confused with the uniform generally contracted pelvis.

The patient is 158 cm. high, with large, full and mature breasts, noticeably slight in figure with narrow hips and strongly converging genitocrural folds. The physiologic lumbar lordosis is diminished, no kyphosis, no rostration of symphysis, iliac venters rather straight and no evidence of early rachitis.

External measurements with tape and pelvimeter give sp., 19.0 cm.; crests, 22.0 cm.; troch., 26.0 cm.; Baudelocque, 19.0 cm.; circumference, 77.5 cm.; left oblique, 19.5 cm.; right oblique, 20.5 cm.; post spines, 8.5 cm. (average 7.5); and on same plane with sacrum. The sacrum is 16.0 long (average 10.3) and very narrow. Tip of coccyx to lig. arcuatum 7.0 cm.; tip of sacrum to lig. arcuatum 9.7 cm. outside, or allowing 1.0 cm. for thickness of sacrum 8.7 cm. inside (Klien's average 12.5, Garfunkel's average 12.3 cm.). The distance from tuberosity to tuberosity measured by the Breisky or Chantreuil methods and the Ayers pelvimeter was 8.5 cm., there being no practical difference in the result from either method.

The tip of the sacrum is easily accessible by the vagina and the coccyx projects acutely into outlet without ankylosis. The pubic arch is narrow, the symphysis high, the ischiatic spines also project markedly into the outlet. The linea innominata appear to be almost parallel, and the attempt to measure the conj. diag. never succeeded, as the promontory was apparently pushed upward and backward and was inaccessible to examining finger.

The inlet measurements were made directly before closing the abdomen and gave c.v. 11 cm. and transverse of 13.0 cm. Thus the inlet is as large as the average and the outlet is contracted in both diameters.

CLASSIFICATION.

Klien, who has made an exhaustive study of this pelvic deformity, classifies the varieties as follows:

1. Funnel pelvis with normal or only slightly diminished conjugate of strait in which—
   - A. Distance between the two tuberosities is only relatively short, but distance from tuberosities to sacrum is so small that both together make labor impossible.
   - B. Distance between the two tuberosities is absolutely so small that the head can not pass
2. Funnel pelvis with conj. of pelvic strait absolutely too short for head to pass unreduced—
   - A. Without shortening of transverse diameter of outlet.
   - B. With contraction of transverse diameter of outlet.

The very great importance of the pelvis strait is here well emphasized. Contraction in the sagittal diameter may be so great that the unreduced head can not possibly pass, even though the tuberosities are far apart—on the contrary, the antero-posterior diameter of strait may be normal, or relatively so, but the contraction of the distance between the tuberosities is so great that this point assumes the position and importance of the pubic arch, the occiput stems against it and the head is forced so far back that labor is impossible.

In the study of 439 labors Klien makes the following deductions, which I quote in brief:

> Where the pelvis is otherwise normal and the distance between the tuberosities is less than 9.5 cm., a mature child will give trouble during labor whenever the presentation is pelvic or shoulder.
>
> For unreduced heads in vertex position the boundary line for serious but not insuperable obstruction is found when the distance between tuberosities is 9.8 cm., other pelvic measurements normal.
>
> The conjugate of the pelvic strait is absolutely too small to permit the passage of the mature unreduced child when it is under 9.0 cm.

Hence, in classifying our pelvis according to Klien's system we find that the conjugate of the strait being less than 9.0 (8.7 cm.) and the marked transverse contraction of the outlet being associated therewith, it should be placed in group 2 B., which corresponds to the uniform generally contracted funnel pelvis of Schauta. According to Klien it is impossible for a mature unreduced head to pass this outlet.

ETIOLOGY.

Very little can be said concerning the etiology of this pelvic anomaly. Schauta believes it results from an original abnormal formation (abnormal height of small pelvis), whereby the promontory is placed high and pushed back, and under the influence of the body weight the shape is brought about in a manner similar to the kyphotic pelvis.

The altered direction of the burden explains the further changes in the reciprocal positions of the pelvic bones which unite for a common purpose.

While unable to add to this unsatisfactory explanation, I would like to emphasize the fact that the significant length of the sacrum and the abnormal height of the lateral pelvic walls must, in a normal convergence of the same, produce a definite contraction of the outlet as compared with the pelvis of normal height.

In support of the theory which minimizes the influence of the body weight, Fehling (confirmed by Thompson) shows that transverse expansion of the brim is present even at the third month of intrauterine life, and that the "long oval" form supposed to be normal in the fetus and newborn is a rare and pathologic—hence the name "infantile" as applied to the funnel pelvis is a misnomer. He concludes: (1) that the transverse expansion depends on the original formation and appears early, hence its production by the body weight is superfluous; (2) that sexual differences are generally present from the fourth month intrauterine, and are perfectly distinct at birth. These facts support the theory that the funnel pelvis is a primary developmental anomaly, and also if so much importance could be attributed to the unusual distribution of the body weight, a kyphosis might result therefrom, and the evident relationship between the kyphotic and the funnel pelvis could be explained, certainly in some instances, along the lines suggested by W. A. Freund in his paper on the pelekogenous origin of vertebral deformity.

FREQUENCY.

It is almost impossible to secure a definite idea of the frequency of this deformity. In Breisky's clinic at Prague, where more than usual attention is given to the contraction of the outlet, there were found 122 funnel pelves of all kinds among 2,070 contracted pelves, or

5.9 per cent. of the total collection as quoted by Schauta. Klien quotes Munch 17.8 per cent. of contracted pelves, Frankenhauser 13 per cent.

Both Schauta and Klien agree that these statistics are in no sense reliable, since no routine measurement of pelvic outlet is undertaken, and when performed a great variety of opinion exists as to what constitutes "funnel pelvis," and what degree of contraction shall determine. Prickards quotes 3,000 labors at Würtzburg, with 252 contracted, but no "funnel pelvis" is mentioned. Ludwig Savor among 50,621 labors reports four cases. Williams (Johns Hopkins) 1,000 labors with no funnel pelvis. Dobbin (Johns Hopkins) one of masculine type in 350 pelves. Fleischmann 2,700 labors with 24 cases of funnel pelvis, which subsequent writers agree must be of slight degree. Schroeder says: "This is a very rare form of pelvic deformity, and even more rare is contraction to a serious degree." Ahlfield gives 8 cases of all kinds in 3,000 labors at Marburg. Olshausen in discussion says: "Very rare, one always thinks of kyphosis."

Klien states that pelves which conform to No. 2 B of his classification, namely, with an absolutely contracted sagittal diam. associated with contraction of transverse diam. of outlet, are extremely rare, and he gives only four cases which have been reported up to 1896—one being his own, and the writer has been unable to find another, diagnosed and reported in literature up to the date of the present case, which produced an insuperable obstacle to labor by the natural passage.

CLINICAL COURSE.

It can not be supposed that these deformities occur without producing a pronounced effect on the clinical course of pregnancy and labor. Where the inlet is not markedly contracted the pregnancy will not differ from other cases, and where definite contraction exists the babe will be carried high, but the principal difficulty will occur when labor begins, for contraction of pelvic outlet is more serious than contraction of the same degree at inlet.

In mild degrees of contraction where spontaneous labor is possible the second stage will be prolonged and serious lacerations are probable. Difficulties in rotation will be noticed because the form of the pelvic outlet prevents normal rotation. Pain weakness from the low position of the child in the lower uterine segment with its scanty musculature is also probable, especially in primaparæ. It is in cases of serious contraction of the outlet, however, that most difficulties arise.

As the case is not usually diagnosed until the first labor is well on nearly every variety of obstetric emergency and operation is met. The conditions are worst when the child is mature with an after-coming head.

In Ahlfield's 8 cases are found, 2 forceps operations, 1 perforation, 1 spontaneous premature labor, 2 artificial induction of premature labor, 2 labor stool. Greuser, craniotomy at outlet. Brummerstadt 2 cases, one stillborn, one saved with difficulty and mother died 36 hours later. Landau, 2 cases craniotomy. Jewett 1 case symphysiotomy. Newman 1 case symphysiotomy, mother died, child lived. Winterberg 1 case symphysiotomy, both lived. Klien reports:

Case 1.—Tub., 7.6 cm.; ant. post., 12 cm.; forceps after long tedious labor. Second stage, nine and one-half hours, laceration cervix, pressure necrosis in vagina; recovery. The head was easily configurable in this case.

Case 2.—Tub., 8 cm.; ant. post., 12.25 cm.; head four hours visible at outlet; forceps; good result.

Case 3.—Tub., 7.6 cm.; ant. post., 12 cm.; version and ext.; good results.

These cases, quoted in brief, serve to show the difficulties associated with labor in this variety of contracted pelvis. In all of Klien's cases the contraction was transverse only, antero-posterior diameter normal, which accounts for his results. Where the head is small and easily configurable, and this I regard as most important, the results are moderately satisfactory, especially if the space between the tuberosities and the sacrum is large enough to permit the passage of the head, but a very slight anomaly, such as a small protrusion of the ischiatic spines will disturb the entire mechanism and possibly cause death of mother or child, or both.

Another feature of this pelvis which has an important bearing on the severity of the labor, is the height of the lateral walls and the length and straitness of the sacrum.

Undoubtedly the long converging walls which are characteristic of the true "funnel pelvis" are the frequent cause of errors in rotation and position, which seriously complicate a condition already sufficiently grave.

PROGNOSIS.

Prognosis in general is not favorable in these cases, but the result depends on the degree and variety of contraction, and especially on the operation, which latter in turn depends on an accurate appreciation of the size and shape of the pelvis.

If left to Nature the soft parts experience deep crushing injuries, which in some cases expose the pubic rami besides producing fistulæ from the long compression. The extreme distention of the lower uterine segment may lead to uterine rupture. For the child the danger of asphyxia is greater than in other deformities, owing to the earlier escape from the uterine body. We find also the characteristic pressure marks appear on skull of babe and even fractures occur. The prognosis is most favorable where the fetal head is small and easily configurable and the outlet is contracted in one diameter only.

POSSIBLE OPERATIONS.

The measurements of the child's head in the present case demonstrate conclusively that its passage unreduced through the pelvis was impossible, and even if the head had been easily configurable, instead of hard and well ossified, I believe the birth of a living child could not be expected. These conditions could only result in a long, hard labor, with operative termination and doubtless a dead child.

In view of the strong desire of the parents for a living child the various operative procedures were carefully considered. The induction of premature labor naturally came first in point of time, and with the modern aids to the preservation of the child after birth, presented many hopeful features, but aside from the uncertainty of the date of conception there was continually in mind the imperfections and uncertainties of our means of determining the size of the fetal head, either by instrumental or external palpation and the necessity was urgent to determine not alone the size, but especially the form and consistency of the head, and as this could only be approximate at best, the success of the operation becomes highly problematical, even in cases where the time of conception is approximately known.

Besides this, the fetal mortality for many reasons is large, and shows, according to Krönig, a variation from 55 per cent. in the pelves showing the most contraction to 25 per cent. in pelves with c.v. between 9.5 to 10.5

cm. Consideration must be given also to the fact that premature children show a large mortality during the first year of life (from 19.5 per cent. to 28 per cent., as given by different authors), which directly or indirectly may be attributed to the prematurity, and the maternal mortality in these cases is from 1 to 2.2 per cent.[1]

Hence the chances seemed slight that a living child could be promised by this method, and it was rejected. The choice then rested between symphysiotomy and conservative cesarean section at term. The statistics give approximately the same mortality for each (2 to 10 per cent.), and a fetal mortality ranging from 15 to 25 per cent. in symphysiotomy as compared with 2.5 per cent to 5 per cent. in cesarean section, and in accordance with these conditions the cesarean operation was decided on as giving a maximum chance for a living child and a maximum of safety for the mother.

FUTURE PREGNANCIES.

The termination of this pregnancy has been in every sense satisfactory, but as the patient is only 21 years old and has the greater part of her sexual life before her, we must consider her future pregnancies. The moral question of sterilizing a woman by removal of the tubes or a portion thereof after the cesarean operation is still unsettled, but there seems to be no justification for depriving the woman of her ability to conceive and bear children when the mortality by the various operative procedures is so low. Both the cesarean operation and ventrofixation seem to lessen the chances of subsequent conception. But we can not rely on sterility, and it is probable that pregnancy will again occur. The adhesion of the uterus to the abdominal wall amounts to a ventrofixation and must be considered in reference to subsequent pregnancies. Abel reports several cases of abdominal adhesions after cesarean section where the operation was done two or three times on the same patient.

If the adhesions remain broad and firm (1/3 of the cases) the course of the pregnancy will be materially interfered with and expansion can occur only in breadth —the uterus can not rise toward the sternum—the axis will not correspond with the pelvic axis and malpresentations will occur, and abortion takes place in about 8 per cent. of the cases.

If pregnancy goes to term the risk of sepsis in subsequent operations will be diminished where the adhesions permit opening into the uterus *in situ* without entering the peritoneal cavity (Spencer). Usually these adhesions produce some stretching and tearing pains during subsequent menstruation, but inside of a year, or during the first half of the next pregnancy they disappear or remain only as long loose strings which cause no difficulty.

A review of the patient's first pregnancy and labor, in the light of our present knowledge, shows that the version and extraction was unwise; indeed, when the head is non-configurable version must not be attempted, for Klien's report demonstrates the aftercoming, non-configurable head is impossible of delivery in such a pelvis. Head-first labors give a possibility of delivery when the child is premature and head soft, and under such conditions version is permissible.

Either craniotomy or cesarean section should have been done, with a preference for the first, since she had been repeatedly examined, but there seems to be no valid reason against terminating all subsequent pregnancies in this patient by cesarean section.

THEORIES OF THE TRANSMISSION OF HEREDITARY SYPHILIS.*

ALFRED SCHALEK, M.D.
Instructor of Dermatology and Genito-Urinary Diseases, Rush Medical College.
CHICAGO.

The fact of the heredity of syphilis was known to Paracelsus, who, in the year 1560, asserted that this disease was due to some unknown virus circulating in the blood, which also infests the semen and during conception is *transmitted with it to the fetus.*

Still, at the present time, we are not able to recognize positive laws as to the methods and conditions of the transmission of hereditary syphilis, and must fall back on theories based entirely on empirical conclusions. Until the specific micro-organism of syphilis is demonstrated scientifically and beyond doubt, these theories will never be more than probabilities—the more so as we find ourselves heavily handicapped in the attempt to make use of our clinical material. The protean nature of syphilis, where we might say that exceptions form the rule, the necessity to observe cases over periods of many years and finally our dependence on the history of at least three persons involved—an evidence which is none too free from objections as to its trustworthiness—all these factors make it difficult to arrive at satisfactory results.

We do know that syphilis is transmitted from the parents to the fetus. The questions which arise next are the following: 1. Which of the parents may be responsible for the transmission of the disease? 2. What are the ways and means by which the virus is transmitted? 3. What are the circumstances most favorable for the hereditary propagation of the disease?

The possibilities of a communication of the virus to the fetus are threefold: the generative organisms, the sperm cell or the ovum, or both, may contain the contagious substance a priori; the fetus may become infected through the maternal blood circulation; and finally, all these factors may act in combination. To determine how much is real in these different influences, to which the transmission of syphilis is attributed, we must take the problem to pieces and examine one after the other separately.

INFLUENCE OF THE FATHER.

The point whether syphilis can be conveyed to the child by the father alone, without infection of the mother, is a subject of much controversy. We shall now try to establish such a possibility on the basis of logical conclusions. To prove this supposition we must in the first place be able to exclude any participation of the mother, and for this reason be absolutely certain of her health. The mere absence of specific manifestations are not sufficient evidence of this. Cases have been reported by Lewis, Barthelemy and others where women, known to be syphilitic, remained entirely free from syphilis for a time up to fourteen years and yet continually gave birth to diseased children. A more confirmatory proof of absence of syphilis in the mother is likely to be found in such cases, where perfectly healthy children were born, when the syphilitic father underwent treatment, to be followed by diseased children, when treatment was suspended. The objections which have been brought forward against these records were that frequently treatment of the syphilitic father was not successful in procuring a healthy progeny unless the mother herself, who never exhibited any symptoms of the disease, has undergone specific treatment; but this seeming contradiction may be explained by the assumption that the mother was already infected either directly or through the placentar circulation by one of her first offsprings (the so-called *chock en retour*), and then participated in the transmission.

---

[1] *Heyman: Arch. f. Gyn., Bd. lix, Heft. 2, 1899.*

* Read by invitation before the Rock Island County Medical Society.

An undeniable evidence of the absence of syphilis in the mother during conception and pregnancy would be the fact that she became infected with syphilis after the birth of her syphilitic child; it is known that people once syphilized become, with very few exceptions, immune against a new infection. But according to the law, which was first observed and recorded by Colles, these cases are extremely rare, and even then not distinguishable from reinfections and therefore impracticable for our argument. Baumes[1] and Colles[2] have first brought out the fact that mothers of syphilitic children are immune against syphilis; innumerable observations have shown that mothers nurse their syphilitic children with impunity, while wet nurses acquire chancres of the nipple, followed by specific manifestations. Caspary[3] went even further and inoculated a woman who had aborted a syphilitic fetus, but had always been free of any syphilitic symptoms, with the secretion of an active syphilitic lesion; the result was absolutely negative—the woman remained healthy. This immunity may be acquired in two ways: the mother may have been infected directly by her husband and the manifestations of syphilis were so mild that they were overlooked entirely, or the virus has been conveyed to her secondarily from the fetus through the placentar circulation. Finger[4] claims that the placenta acts as a perfect filter and wholly prevents the passage of solid particles of matter, but that the products of syphilitic infection are ptomains or toxins, which are soluble and may traverse in the interchange of placentar serum. This process does not necessarily render the mother syphilitic, but confers on her an immunity, an effect which would be the same as that of vaccination for immunization against smallpox.

Still another way to prove the spermatic transmission is by analogous evidence. Pasteur[5] discovered that the germs of the disease of silkworms, called "pebrin," pass into the spermatic cells of the worm, which still retain the power of germination, but simultaneously transmit the infection to the offspring. Similar experiments by Baumgarten have shown that the inoculation of chicken eggs with tubercle bacilli has resulted in the production of chickens with evidences of tuberculosis. All these observations prove that the infectious material may be communicated to the normal ovum by external agencies, including the semen, and result in a diseased product. We are certainly entitled to the belief that the same principle applies to the human organism.

While the majority of syphilographers shares this opinion, others, as Cullerier, Charrier, Parry and Notta, assert that the transmission of syphilis from the father to the child is impossible without participation of the mother. In evidence of this, they published many cases of recently acquired syphilis of the father where neither the wife nor children suffered from the disease. These records are not free of objections from unbiased investigators. Beside, if their view is correct, it would do away with the most probable explanation of immunization of the mother; that is, through the medium of the fetus. We would then have to ascribe the immunity of the mother in every case to a direct infection from her husband, and assume at the same time that this acquired syphilis had always run such an extraordinary mild course as to be overlooked entirely, a theory which does not appear very plausible.

The pathologic changes in the placenta may in time clear up some of the mooted points. Fränkel finds different conditions in the placenta, according to whether the disease has been conveyed by the father alone, the mother being healthy, or when the mother also is syphilitic. In the first case the placenta is affected along with the fetus, displaying a cellular granulation growth, complicated with obliteration of the blood vessels of the villi and marked thickening of the epithelium; in the second case not only the maternal and fetal parts of the placenta are involved, but the endometrium may also show a gummatous condition.

INFLUENCE OF THE MOTHER.

There is no doubt whatever that syphilis is transmitted from the mother to the child, while the father is and remains healthy. A woman suffering from syphilis may affect the fetus in two different ways, either directly through the vitiated ovum or by furnishing it during gestation with elements of nutrition imbued with the specific diathesis. Both these influences, or either one alone, may act if she had syphilis at the moment of conception. That the ovum alone may be responsible for the transmission is probable from the analogical action of the paternal procreative cell since we are justified to assume the same faculties for the female generative organism. If the mother contracted syphilis subsequently to fecundation, the transmission of the disease to the fetus could have been caused only through the placentar circulation. In all these cases the health of the father must be assured as proven by a later infection. An infection of the child during the passage through the birthways, which belongs in the class of acquired syphilis, can easily be excluded if pathologic lesions characteristic of hereditary syphilis are found.

The final conclusions as to the influence of either of the parents on the child could then be formulated from the above arguments as follows: 1. The father's sperm cell may contain the syphilitic virus and convey it to the child without participation of the mother. 2. The maternal generative cell may contain the virus and result directly in a diseased fetus. 3. The placentar circulation permits the passage of the infectious matter either way from mother to child, and vice versa. 4. Several or all of these factors may combine, and the more of them that are present the less probable the escape of the child. 5. The probabilities of the transmission of syphilis through the mother are greater because of more ways of possible influence on the fetus.

The next question to be considered is, what are the pre-existing circumstances and conditions most favorable for the transmission of hereditary syphilis? From our clinical experience we may positively assert that the probability of the appearance of hereditary syphilis is reversely proportionate, 1, to the time of infection of the parents, and 2, to the length and thoroughness of specific treatment. The nearer to the time of fecundation the infection of either parent took place the more certain is the disease to become evident in the child and the more malignant will be the type of its manifestations. Some writers claim that this applies mainly to the man in whom the syphilis, after a period of years, enters a state of latency and loses its contagiousness. It is no rare occurrence, however, they say, for a woman to give birth to a syphilitic child ten years and later after her infection; they explain this by reasoning that an ovum infected with the syphilitic germ may be retained in the ovaries for a long time before it is expelled and fertilized, while the spermatic cells are eliminated constantly, and with them the specific virus as long as it is present. The other influential factor is the effect of treatment. A judicious, methodical and sufficiently long-continued treatment of the syphilitic parent will, in many cases, result in a favorable fate for the offspring.

Another interesting question is: At what period of pregnancy may a woman become syphilitic without communicating the disease to the child? Ricord's belief that infection of the mother within the last three months of pregnancy does not affect the child, was generally accepted until cases were reported where syphilis, acquired by the mother as late as the eighth month of pregnancy, was transmitted to the child.

Can hereditary syphilis be transmitted to the second generation? To prove this we must have positive evidence, 1, of acquired syphilis of either, or of both, of the grandparents; 2, of hereditary syphilis in either of the parents with the absolute proof that no new syphilitic infection of the parents took place, and 3, of hereditary syphilis in the grandchildren. The difficulties attached to the task of acquiring a trustworthy history of a disease running through three generations, make the reliability of the reported cases very uncertain and do not, therefore, permit any correct deductions.

In conclusion I would like to add a few practical points which, in connection with this subject, may be of interest.

While the energetical treatment of syphilis will help a great deal to reduce the probability of its hereditary transmission, still the more important task of the physician is to prevent marriage at a time where the disease is still active and prone to be propagated. According to Kassowitz,[6] about 30 per cent. of syphilitic children die *in utero*, another 30 per cent. die within the first six months after birth, while the balance is still more reduced by diseases developed on a tainted system. As long as there is no absolute proof of a positive cure of syphilis, a thorough, systematic treatment of at least two years' duration and an absence of specific manifestations during three consecutive years should be made the condition *sine qua non* for the consummation of marriage.

THE TREATMENT OF LEPROSY.*

A. H. OHMANN-DUMESNIL, M.D.
ST. LOUIS.

Leprosy, that awe-inspiring scourge of the human race, stands to-day an unsolved problem awaiting a proper solution. It is the great riddle of the Sphinx which some unknown Œdipus may perhaps solve. From time immemorial it has engaged the attention of the most learned sages, philosophers and men of science, and it stands to-day as mysterious and as awful as it did at the beginning. It is the black and lowering cloud over humanity which even we, with our boasted scientific attainments, have not yet been able to dispel, and all our puny efforts have resulted in the same failures that the misdirected labors of our forebears did. It is the one problem before which every one must bow and acknowledge *non possum*. It is the most stubborn, as well as the most difficult with which to grapple, of the great triad, the two other members of which are tuberculosis and syphilis.

The great similarity to one another which these processes present has led to the idea wrongfully entertained by some that one was merely a different stage of the other; as, for instance, that leprosy is the quarternary stage of syphilis, when we know it to be a fact that the two diseases have no such close relationship; and so for tuberculosis. What we do know is, that all three are essentially chronic in character and insidious in their beginning. They are also essentially destructive in character and they all attack every tissue of the human organism. We further know that leprosy and tuberculosis present specific bacteria of the bacillus form, and the best investigators are of the opinion that syphilis also is characterized by a specific bacterium. It is also held to be most probable that the bacteria are not the direct causes of the diseases, but rather their toxins, a most reasonable view in consideration of the fact that serum therapy, based on this manner of considering the subject, has proven so successful.

There is another point of more than ordinary interest in this whole question, in view of the fact that it is the one of highest interest to the victim of any one of these diseases, which is, what is the proper treatment and is there a cure? In the case of syphilis we are positively assured by some that there is an absolute cure, whereas others deny it. A third class tells us that the disease cures itself spontaneously. It is certainly a difficult matter to decide such a question, especially when our methods for a final determination are so defective. So far as tuberculosis is concerned, we have given to us positive assurances that it can not only be cured, but that it has been in numerous instances. And yet, even here, some doubting investigators have more or less maliciously demonstrated some remains of undoubted tuberculous nature in certain of the reputed cured cases.

Quite different is it in the case of leprosy. A cure has not yet been claimed by a leprologist who knows the disease thoroughly. Marked improvements under certain forms of treatment have been noted, and no one has denied these; but a cure has only been suggested as possible under the treatment which has been employed. But of this I will speak later on in the course of this paper. What I purpose noting is the treatment of the disease, and this will, very naturally, give rise to a few remarks on subjects connected with it. I do not purpose speaking of the cure of leprosy, for this has not yet been discovered. The methods of study have been improved and we are daily making some steps which bring us nearer to the wished-for solution of this great problem. We can not say that it is impossible; we can only acknowledge that our methods are impotent.

---

* Read at the Fifty-fourth Annual Session of the American Medical Association, in the Section on Cutaneous Medicine and Surgery, and appro[illegible] publication [illegible] Drs. L. Duncar

The problem which confronts us is to devise, discover or formulate a successful method for the cure of leprosy. For its complete eradication perfect isolation is sufficient; for its cure we must have something equally as certain.

It is not proposed here to speak of all the methods of treatment of leprosy, for their name is legion, and the majority of them have fallen into ignominious desuetude. They have been tried and found wanting and have fallen into a merited oblivion. Many of these methods were based on superstition, the craft of magic, white or black, religious recitations, incantations, amulets, prayers, ex-votos, and the entire arsenal of the belief in the miraculous and outlandish. These are still practiced in districts remote from all the semblance of even the beginnings of civilization. And we have no doubt that certain creeds have followers to-day who believe or pretend to believe that they cure even leprosy by their prayers, which are really blasphemies in the eyes of those whose faith is pure and true. With all these we have nothing to do. What will be considered are medical measures and the success which has so far attended their exhibition; and of these but a few will be chosen and such as have proven of some value.

It may not be inopportune, before entering into a consideration of the different methods of treatment, to pass in short review some of the views which have been held in regard to the manner in which the disease is acquired. There are those who have invoked telluric influences, especially dampness, and yet the disease is seen to occur in places of such varying meteorologic conditions that this can not be considered as entering into the question any more than a hot or a cold climate. For leprosy is observed to occur in the torrid heat of India and in the glacial zone of Norway as an endemic disease. The theory that it occurs principally in those who live on the sea coast and, incidentally, chiefly in fish eaters, as has been advanced by Mr. Hutchinson, is not supported by facts, as is aptly proven by its occurrence in those who have never been near the sea and those who have never eaten fish, either from fresh or from salt waters. Then we have a cause which has been invoked, which has met much opposition and which has caused, as it is yet causing, much acrimonious discussion. Of course, you will immediately recognize this cause as contagion. The contagionists advance some very good arguments in support of their views, and the non-contagionists are not slow to adduce facts to prove their position. The most active among the latter is, beyond all doubt, Zambaco, who has made it the object of his life to endeavor to prove the non-contagiousness of leprosy. He makes a very strong plea for this view in his "Voyages parmi les lépreux," a small book full of very interesting matter, rendered doubly so from the fact that it is from the pen of a capable leprologist. That this question of contagion is anything but easy of solution is evidenced by the fact that the lepra conference held in Berlin did not pronounce itself definitely on the subject. Under these circumstances it has been considered the safest course to follow by both sides party to this discussion to agree on isolation as the best measure to pursue until something more definite is known concerning the nature of leprosy.

Another theory to account for the increase in leprosy, and it is one which has a number of adherents, is the one which makes the disease a hereditary one. This manner of thinking is one of the offshoots of the non-contagionists. They contend that, while lepers are, as a rule, sterile, they propagate to a sufficient extent to furnish a continually increasing number of lepers, and where the sexes are not separated the intermarriage or concubinage of lepers with non-leprous individuals inevitably results in the production of offspring which are lepers. And, as a further proof of heredity, is adduced the fact that the disease will skip a generation to appear in the succeeding one. It is this question of heredity which has led so many eminent leprologists to advocate a strict system of segregation, which, if carried out properly, is certainly destined to ultimately cause the disappearance of leprosy were it not for one factor which should be taken into consideration. This important factor is inoculation. No one denies the inoculability of leprosy, but all are not yet agreed on the method in which it occurs. The introduction of the bacillus of Hansen directly into the human tissues or through an intermediate host function has been proven to be possible. These bacteria have been found in the soil on which homes of lepers were built, and subsequently destroyed by fire for the purpose of destroying all possible causes of future infection. Mr. Impey of South Africa has successfully inoculated leprosy in some natives so that we may look on the inoculability of leprosy as a proven fact.

Now come certain students of leprosy who contend that the disease can not be inoculated except under certain conditions. They further contend that these conditions must be present, and, as a matter of fact, are usually present; all of which is yet a matter of *sub judice*. Many of these also sustain the thesis that there exists no such thing as cases of leprosy acquired through contagion, and that all are inoculated. Some very harassing discussions owe their origin to the proper interpretation of the terms contagion and inoculation, but this is neither the time nor the place to indulge in hair-splitting distinctions. That which concerns us more is a consideration of the conditions which are regarded as necessary to the acquiring of leprosy. In the first place, and regarded as the most important, is the existence of a predilection to the disease. This is considered a racial condition and accounts for the rapid dissemination and increase of leprosy among certain peoples or races. Of course, this is merely a theory which, unfortunately for its upholders, is not supported by facts. A short inquiry into its weak points may not be uninteresting. In this theory of predilection it has been found necessary to call in certain racial characteristics. Thus the Chinese, Japanese, Hindus and Sandwich Islanders were considered sufficient at first. Then it became necessary to add Norwegians and the Indians of the different North American countries, which very naturally led to the inclusion of the natives of the West Indies. This gradual accretion has finally resulted in the inclusion of all countries with the exception of nearly all the European states and of the United States. And yet we find that the natives of some of these become lepers, albeit purely Caucasian. The argument that these have traveled in countries where leprosy is endemic and lepers are common and thus acquired the disease by contagion will not hold. For cases are noted and I have seen some in which the disease was sporadic; in which the affected individuals not only never traveled where leprosy was ever observed, but had never seen or had any dealings with any one who might have a predilection for leprosy. It is true that such cases are few in number, but there are enough of them on record to prove a stumbling block in the road of those who spin fine theories out of very weak material. But it would certainly prove a wearisome task to take into consideration all the theories which have been advanced and examine into the validity of the arguments which are made to hold the various views which are announced. Enough has been said to give an idea of one of the many problems set before leprologists and of the difficulties which surrounds the task of arriving at a solution of any one of them. With these few preliminary remarks to introduce the subject I will now enter into a consideration, necessarily short, of the question of the treatment of leprosy; and, in this, I do not propose to give a complete and detailed account of all those which have been proposed and tried, but rather pass in review a few which have offered the most encouragement and seemed to be the most rational in their application as well as the best in the results obtained by means of them.

In speaking of the treatment of leprosy the first agent to which we naturally feel our attention called is chaulmoogra oil. It is perhaps the oldest one which has been employed in the treatment of leprosy, and even to-day it enjoys a reputation far superior to all others on account of the very good effects which have followed its use. Originally used in India, if we are to believe those who have written of it, it is still regarded there as the only medicinal agent of any worth in this disease. And it is not only in India, but in other countries as well that it enjoys this exalted reputation. Those who have had an opportunity of observing its action and its effects in a cold, deliberative manner, are also ready to accord to it the praise which it certainly deserves. But to attribute to it the power of curing which has been claimed for it none who has observed it is willing to concede. It is universally admitted as a fact that it will bring about improvement in a case of leprosy, but that it will cure is conceded by none. And it is right here that the function of the leprologist is called into active requisition. In a case of reputed cure he should examine it with all due regard and not jump at conclusions because external appearances of a general character are such as to lead to a mistaken idea that no leprosy exists. Every small symptom and sign must be carefully noted and the complete absence of all must be looked on as deceptive, for it must never be forgotten that while chaulmoogra oil improves much, it has never yet cured leprosy. And right here let me warn you in regard to the administration of this remedy. It is fairly well borne when given by the stomach, but the time inevitably arrives when the nausea and other untoward symptoms which this method produces force it to be administered hypodermically. This should be done at the very beginning, and the oil should be applied externally. In this manner much better results may be obtained, although the hope of a final cure by this means may be considered *nil*. We are well acquainted with the claims which have been made for this agent, but none has ever been substantiated in a manner that would prove satisfactory to one who has made this disease a study. In fact, the result has usually been the reverse. Not very long since a Chinese leper, who was quarantined on the grounds of the St. Louis Smallpox Hospital, was declared cured by the medical superintendent. Among those called to examine into the alleged cure was the reader, who unhesitatingly declared that the Chinaman was not cured of his leprosy, and he was ordered back to his isolation. He still presented some indubitable marks of the disease, and, in point of fact, was not cured. This opinion was shared in by the others who examined him.

It has ever been thus with cases declared cured by oil of chaulmoogra, and doubtless will be. One point to which attention should be called in connection with this agent is that in reputed cured cases there is always present the liability of a relapse into a form which will be more severe than the original one for which it was administered. This is an evil of more than ordinary importance, and it is on this account that those acquainted with the fact have hesitated about using this medication. Promises can not be safely made beyond a certain point, and a severe relapse is certainly very difficult to explain. The enthusiasm of one who has seen but a portion of the results is not sufficient to guarantee the hope of a final cure, and the experience of him who has not devoted years to the study of the subject and who has not had the opportunities of following any form of treatment can not be taken either as a positive proof or as a reasonable encouragement to adopt a method which has proven itself fallacious on so many occasions. Do not depend on oil of chaulmoogra even for a temporary improvement; it is better to resort to other methods.

You will no doubt find many advocates of this oil, and if you do, inquire into their experience and ask them for how many years did reputed cured cases remain cured. Everything in this matter must be carried on in a judicial manner, and the *ipse dixit* of no one can be accepted. Let not the wish be father of the thought, but consider only those things which are proven. We can not afford to jump at conclusions to-day; we can not even afford to accept what are but factitious proofs. The absence, supposed or absolute, of Hansen's bacillus is not always a positive proof of the absence of leprosy. Besides, in such a case, what proof is afforded that this self-same bacillus is not lurking in some tissue beyond the reach of the investigator? Who is it that will be enabled to examine every organ and every tissue of a living subject and who will take the pains to do so with a dead one? As you can plainly see, the honest investigator is seriously handicapped in an honest endeavor to determine whether a case of leprosy has been or has not been cured, no matter what treatment has been used. But, to briefly summarize the expressed opinions on the use of chaulmoogra oil in the treatment of leprosy, it may be stated that all investigators as well as leprologists are of the opinion that it has a rapid effect in the way of improving any case. Also, that it is best administered hypodermically; and, furthermore, that its discontinuance is attended by relapses of a more or less severe character. Furthermore, all are agreed that it can not be continued very long by the mouth. These are certainly not very encouraging conclusions, and would lead very few to the adoption of this agent in a country where the propriety of complete segregation is under consideration. In fact, it would lead to the use of other means which would encourage the hope of ultimately successfully obtaining a cure. This is the objective point of all leprologists, and will explain why all frown down any method which can not afford anything better than relief.

This treatment by means of chaulmoogra is purely empirical, and not based on any rational cause therefor; it was simply found to be good to produce an improvement in the symptoms of leprosy, and this led to its adoption in the treatment of the disease. And, up to the present, but little improvement has been made in its administration beyond that of employing the hypodermic method in lieu of that by the mouth. Naturally the former method has resulted in the advantage of its being possible to continue the remedy for a longer period of time without any untoward symptoms; but no better final effects have been observed. This is certainly demonstrative of the fact that the method does not repose on a rational therapeutic base, but is rather in the nature of a haphazard measure, in which a partial effect only is taken, and very illogically, as an indication of what the permanent result should be.

Another method to which I desire to allude is that which was inaugurated by P. G. Unna of Hamburg, and which was based on his pathologic findings. As is well known to all who are present, he claimed that lepra bacilla are aerobic and need oxygen in order to continue to exist. It matters but little whether these bacteria be distributed along the walls of blood vessels and lymphatic channels or whether they be located in the substance of cells. The theory which he promulgated was, in substance, to use such agents as are greedy for oxygen and by their aid deprive the bacteria of that on which they depend for existence. These agents he found in that class he has so well described—the reducing agents. He expected great things from ichthyol, and his results have been what I have found them to be: improving but not curing. I will not burden you with the details of his method and its modification. It is sufficient to state that it has never produced more than an improvement. It has never cured. That in which we are more particularly interested is the question of a treatment which will cure. The therapeutics of lepra is improving daily, and we can not rest satisfied with the dictum that it can not be cured, any more than we can be with the unproven assertions that certain methods which are prematurely lauded have effected such a result. It is, indeed, a burning question in view of the fact that so many cases of this disease exist and that it is apparently increasing the number of its victims. The only manner of successfully combating it is to cure, not to attempt to repress it. Attempts at repression are but too frequently futile and amount to nothing more than a *pis aller*. Segregation and complete isolation will dispose of the cases found and recognized, but can hardly prevent the development of new ones, which experience will lead to conceal themselves and thus encourage the formation of new foci from which lepra will be disseminated until it again assumes large proportions.

It may perhaps be best to merely mention some alleged cures for lepra which, unfortunately, have not yet been proven to be such. One which has been announced with a great flourish of trumpets by its originator is the treatment by means of the Carrasquilla serum. As has occurred in the introduction of all new methods in so-called incurable diseases, wonderful improvements were observed, and even apparent cures. As in all these cases the inventors were filled with the enthusiasm produced by the delight of having at least discovered a possible cure; and, as has been the fate of all, the ultimate results have been failures. Critical experiments made by competent observers have resulted in unfavorable verdicts, and the alleged wonderful cure has hardly lived long enough to be even a nine days' wonder. It has ever been thus with all these alleged cures for lepra. So many have the disappointments been that many who began with high hopes have become disheartened and merely plod along the beaten tracks of the past, which, at all events, offer some little modicum of satisfaction.

The latest treatment which it has been attempted to make a vogue is that by serpent's poison or the so-called antivenene method. Accidentally discovered and repeated later on with design, it was hailed with delight on account of the great improvement which was observed to follow its use. Great expectations followed the results which were obtained, but, like all its predecessors, it fell by the wayside and it failed to accomplish the much desired effect, that of producing a cure. Theories and hypotheses, numerous enough and sufficiently varied, were advanced to prove theoretically that it was the Hermetic stone of leprology. And it, too, failed. It were a loss of time and a trespass on your patience to recount all the will-o'-the-wisps of leprology. It would be sad to give naught but a catalogue of failures, and yet these are the monuments which line the highway along which leprologists have been traveling for many, many years. The fairy edifice of cure is as far away as ever and seems as difficult to reach as the foot of a rainbow.

The solution of the problem of the true treatment of leprosy is the one which now confronts us. It is one surrounded by difficulties as well as one fraught with the highest importance. It is the true solution of the whole lepra question which, unfortunately, has aroused but comparatively little attention from the governments of the civilized world. The number of those afflicted with lepra, the cost of maintaining those who are unable to earn a living and similar economic considerations are the only questions which have aroused any interest. Not enough attention has been given to the treatment of this scourge of humanity, and yet this is the paramount issue at the present time. This treatment must, of a necessity, be curative. After all has been said there can be no doubt whatever that the cure of lepra is the paramount issue. Leprologists, who are such in the true sense of the term, do not concern themselves much about the palliative treatment of the disease. This is certainly sufficiently well known not to require any further investigations. The methods now known and tried are sufficient for this purpose. A cure for leprosy has not yet been discovered, nor is it my purpose to announce one. The conditions which are offered in the problem are such that certain lines of investigation and experiment must necessarily be followed. The method in general which holds out the best promises of success is, beyond doubt, that based on serotherapy. This is, comparatively, still in its infancy, and yet it holds out many hopes for an extended usefulness. Roux and Behring have demonstrated the possibilities in the method by the results which have been obtained by the use of antitoxin. Among the conditions necessary to the production of a serum possessing specific properties is the production of a pure culture of the specific bacterium. In the next place, an animal who is immune to the particular disease for which a serum is to be obtained must be found. In the next place, this animal must be of a hardy nature and of a sound constitution when inoculated. Finally, the inoculations must be limited in number, as the serum becomes deteriorated in quality if the animal be inoculated and bled too many times or at intervals which are not sufficiently far apart.

A question of some importance which naturally suggests itself is, what animal would be the best to furnish the serum? In this question are involved many conditions; but, so far as present knowledge on the matter extends, there is little doubt that the male goat and the mule are the animals best adapted to the purpose, both on account of immunity and because their physique is refractory to nearly all the diseases of the capric and equine families. Of course, we have not yet arrived at that point when anything of a definite nature can be positively stated. A most vital corollary to the whole question is the one involved in the question as to whether, conceding a case has been effected, the cured individual is subject to or capable of being inoculated a second time by leprosy. In other words, does he then become immune to the disease and, if so, is the immunity a permanent one? Of course, this opens up anew the great question of immunity which will not be touched here.

The writer is fully aware that the entire subject of the treatment of leprosy has but been barely outlined in this paper, but it has been offered in the hope that some one will take it up and elaborate it completely and that it may call some little attention to the questions of a cure for leprosy. Now that the American possessions include a number of islands in which leprosy is endemic and cases exist in large numbers, it is certainly the duty of the American medical profession to devote more attention to this disease and to search for a cure with more diligence than it has done heretofore. Those physicians who are located in these possessions have ample opportunities to pursue their studies and make experiments such as are certainly not offered in this country. We perhaps do not hope in vain when we express the one that the opportunities offered will, in time, produce fruit of the highest value to all humanity.

DISCUSSION WILL APPEAR LATER.

ANATOMIC AND PHYSIOLOGIC CORRESPONDENCES OF CHILD AND ADULT.*

W. T. ECKLEY, M.D.
CHICAGO.

I have made an endeavor in this paper to indicate a few salient points of correspondence between child and adult along anatomic and physiologic lines. The task is difficult because: (1) The similarity is so great between child and adult that it is practically impossible to draw a definite dividing-line between the two. (2) There are certain generally accepted adult qualities, such as judgment, discretion, physical and mental precosity inherent in some individuals universally recognized as children. (3) Some persons, adults to all external appearances and known as such among their fellows, have the mental and physical traits of childhood and youth.

This paper will deal in a brief way with: 1. Correspondences in temperature. 2. Correspondences in respiration. 3. Correspondences in circulation. 4. Correspondences in articulations. 5. Correspondences in accessory sinuses of the nose. 6. Correspondences in fetal vestiges. 7. Correspondences in emissary veins. 8. Correspondences in cerebral sensorial areas. 9. Correspondences in cerebral association centers (Fleschig).

I am indebted to J. S. Brown, M.D., of Chicago, for the following brief comparison of the infant and adult as regards temperature, respiration circulation and joint structures with clinical observations.

While in many minor points the infant and adult are nearly identical in their anatomy and physiology, it is essential to note certain differences: (*a*) For the benefit that may result to the infant from non-interference; (*b*) for the peace of mind which the attending physician may thereby secure.

TEMPERATURE.

The temperature in early infancy does not exhibit that stability seen in later life. Immediately after birth it is about the same as or perhaps a little higher than that of the mother. Under the influence of a bath and radiation from the skin it falls in the first few hours after birth from 1 to 3 F. Very soon it rises to 98.5 or 99 F., which figures practically persist during the succeeding months or even years. However, we must note that the infant will for a given cause show much greater variation in temperature than the adult, a circumstance readily accounted for when we consider the relatively greater radiating surface, the dilatability of the superficial capillaries, the thinness of their investments and the undeveloped state of the heat-regulating centers in children. It is a continuous high temperature, rather than a single abrupt elevation which lends significance to diseases of infancy.

RESPIRATION.

According to Uffelmann the rapidity of respiration during sleep is as follows:

At birth	35 per minute.
End of first year	27 per minute.
At two years	25 per minute.
At six years	22 per minute.
At twelve years	20 per minute.

To this I would append Kirk's statement:

> The number of respirations in a healthy adult person usually ranges from 14 to 18 per minute.

Holt, commenting on Uffelmann's statement, says:

> During waking hours this rate may be very materially increased, and from comparatively slight disturbance may be nearly twice as rapid. The type of respiration in infants is diaphragmatic, and it continues to be chiefly so until after the seventh year, when the costal element becomes more and more prominent. The rhythm of respiration is easily disturbed. In very young infants the regular rhythm is seen only in sleep. Regular rhythmical respiration is not fully established before the end of the second year. At times the infant's respiration may be carried on for a few moments almost entirely by one lung, and, indeed, it may also, in a brief time, change from superficial to deep breathing.

Cotton says:

> It has been demonstrated that young infants inhale more oxygen and exhale more carbon dioxid relatively than adults. The ratio of respiration to pulse in very young infants is so inconstant that it is of little value.

CIRCULATION.

Kirk's table on the force and frequency of the heart's action gives the following averages:

Before birth	150 per minute.
Just after birth	140 to 130 per minute.
During first year	130 to 115 per minute.
During second year	115 to 100 per minute.
During third year	100 to 90 per minute.
About seventh year	90 to 85 per minute.
About fourteenth year	85 to 80 per minute.
In adult age	80 to 70 per minute.
In old age	70 to 60 per minute.
In decrepitude	75 to 65 per minute.

Some persons preserve their youthful rate of heart action throughout life, but on the authority of Babcock not without pathologic causes, which, indeed, may be difficult or even impossible to discover.

On the authority of Cabot the following is the cellular constituency of the blood: At birth both the red and white corpuscles are considerably in excess of those in adult life. During the first day the red and white corpuscles increase markedly in number. At the end of the seventh day both the red and white corpuscles have been reduced; the red corpuscles are something near the adult figures, and the white to about 15,000 per mm.

JOINT STRUCTURES.

In the articulation of the bones of the cranial vault sutures are absent, and in their place are fibrous septa continuous internally with the dura mater and externally with the pericranium. At the angles of the parietal bones are six fontanelles which gradually become filled by bone. Ankylosis of the sacral and coccygeal elements of the spine may be mentioned, this process in part being continued well on into adult lift. The diaphyseo-epiphyseal line of junction is of great practical interest, since growth in length in long bones takes place here. Separation of epiphysis from diaphysis, a condition difficult to diagnose from other traumatisms, may occur at this line. And, again, much of the pathology of bone tuberculosis is near this line of union. For evident reasons operations in children near the epiphyseal line should be avoided as much as possible.

ACCESSORY SINUSES OF THE NOSE.

The pneumatic bones of man are confined to the head. They contain, after childhood years, air cavities, variously called cells, sinuses and antra. The naming is founded rather on differences in size than on structural peculiarities, for they are similar in location, development, nutrition, function and liability to local and constitutional disorders. They are accessible from without, and on this fact depends doubtless the frequency of invasion by disease as well as the fine technic of their medical and surgical treatment.

The accessory sinuses are evaginations of the nose, hence their lining epithelial cells are of ectodermic origin. They partake of the nature of the nose because evaginated structures in general partake of the nature of the primitive cavity from which the evagination occurs.

The accessory sinuses occur in the frontal, ethmoidal, sphenoidal and maxillary bones. They are variable in size in different races, in people of the same race, and even in the same person; those of the two sides may differ in magnitude. In short, the sinuses admit of general, not of specific, limitations. Their openings into the nose are relatively larger in the young than in adults, and like other evagination routes, may occur doubly.

The sinuses are tardy in appearing and with no demonstrable reason develop *pari passu* with the generative organs. The completion of the sinuses is heralded by adult qualities of voice. At birth the frontal sinus is absent, the maxillary sinus is a shallow groove on the outer wall of the nose, the ethmoidal cells are shallow depressions and the sphenoidal bone has no traces of air cells.

The pterygoid plexus of veins is situated in the region of the pterygoid muscles and is composed of veins corresponding in name and number to the branches of the internal maxillary artery. This plexus is proportionately larger in children than in adults, and communicates with the cavernous sinus through the vein of Vesalius.

The empiric practice of counter irritation behind the ear, as well as in other regions of the scalp, finds anatomic justification in the emissary system.

In view of the large number and the large size of the emissary veins in children, diligence should be exercised on the part of both nurse and physician in preserving immaculate toilet of the scalp, since septic thrombi gain access to the dural sinuses, as previously pointed out.

Adults are more liable than children to infection of the dural sinus system by septic thrombi from the deep parts of the face. Children, on the other hand, are more liable than adults to epistaxis of cerebral origin, a fact attributable to greater *frailty* of emissary veins and greater constancy of a vein in the foramen cecum.

FETAL VESTIGES.

A number of structures in the embryo survive as vestiges in both child and adult. When their obliteration is complete, as often occurs, the very obliterating process itself is not infrequently a menace to the child's welfare. When the obliterating process is incomplete the survival of the structure may assume medical or surgical importance.

For our purpose let us define an anatomic vestige as a structure which, by virtue of loss of function, has become dispossessed of its specific characters as an anatomic entity. When a structure does not lose its specific qualities then, as a survival, it may acquire pathologic importance. The greater number of fetal vestiges belong to the digestive, circulatory and generative systems.

The embryonal yolk sac is attached to the ventral surface of the alimentary canal by a constricted neck—the vitelline duct. The somatopleure closes in around this duct, leaving the umbilical opening. The vitelline duct usually disappears. In some cases, however, it persists, being attached to the ileum from one to three feet distant from the ileo-cecal junction. When its existence coincides with an unclosed umbilical opening, a fecal fistula results. The persistent duct is called Meckel's diverticulum, and is usually from one to seven inches in length.

Meckel's diverticulum, in adults and children alike, may appear as a very small thread-like structure and still remain pervious. In abdominal operations necessitating invasion of this diminutive variety of Meckel's diverticulum, ligation should always precede its division, in order to avoid the possible escape into the peritoneal cavity of gas or other noxious intestinal contents.

The allantois supplants the yolk sac as an organ of respiration and nutrition. Its stalk passes through the umbilical opening. With the appearance of the placenta the allantois loses its primitive function, certain parts becoming vestigial while other portions assume entirely new functions.

The allantoic vessels become the umbilical vessels and are concerned in the placental aëration of the blood, forming integral parts of the umbilical cord. The intra-embryonal part of the allantois forms the urachus, urinary bladder, urethra of the female, cloaca in part, and the prostatic urethra of the male.

The urachus is usually impervious, still obliteration may fail to occur; when its obliteration occurs coincidentally with an unclosed umbilical opening a urinary fistula results.

The vessels of the placenta—the hypogastric arteries and the umbilical vein—pass through the umbilical opening and obtain in child and adult as subsequent lifelong disturbing factors. The urachus and remnants of the hypogastric arteries assist in delimiting the inguinal fossæ, hence they are causative factors in the determination of inguinal hernia.

The umbilical opening left by the closing in of the somatopleure transmits: 1. The vitelline duct, whose persistent Meckel's diverticulum may result in a fecal fistula. 2. The stalk of the allantois, whose persistent urachus may form a urinary fistula. 3. The hypogastric arteries, whose fibrous remnants are causative factors in inguinal hernia. 4. The umbilical vein, whose cord-like remnant forms the round ligament of the liver. Umbilical hernia may occur in child and adult.

The foramen ovale—the causative factor in "blue baby"—is an unclosed part of the inter-auricular septum. It persists until birth or shortly thereafter. Its ultimate closure may be a matter of weeks or months, or it may persist throughout life. In 200 bodies I found 20 instances in which it was possible to pass a broom straw through the unclosed foramen ovale, but in only three of this number was the opening large enough to be of antemortem importance.

The thyroid body is formed by a median and two lateral diverticula. The lateral diverticula arise from the sides of the fourth inner branchial cleft; the median diverticulum arises from the ventral wall of the pharynx, and extends downward in relation with the ventral surface of the trachea, forming the isthmus of the thyroid body. The proximal part of the course of this diverticulum lies in the conjunctional area of the tuberculum impar and the two symmetrical segments of the tongue. The foramen cecum on the dorsum of the tongue represents *the persistent part of the median diverticulum.* That portion of the diverticulum intervening between the foramen cecum and the isthmus of the thyroid is called the thyroglossal duct, and may persist as accessory thyroid glands and lingual duct.

EMISSARY VEINS.

The emissary veins are more constant in childhood than in adult life. They communicate intracranially with the dural sinuses, extracranially with deep and superficial veins of the face, scalp and neck. They have no valves, hence the direction of the current of blood in them at any given time depends on the relative character of intracranial and extracranial pressure.

The emissary veins pass through foramina in the bones of the cranium. In childhood, these foramina are constant; in adult life, however, some tend to disappear, and their veins become obliterated.

The emissary veins in erysipelas and suppurative diseases of the antrum of Highmore may transmit septic thrombi to the sinuses of the dura mater, in childhood as well as in adults. Epistaxis of cerebral origin frequently occurs in childhood and is due to rupture of an emissary vein passing from the superior longitudinal sinus of the dura mater through the foramen cecum to terminate in the venous capillaries of the mucous membrane of the nose.

The mastoid emissary vein is proportionately larger in the child than in the adult and its severance may cause troublesome and even dangerous hemorrhage in surgical operations in this locality.

The angular vein of the face communicates at the inner part of the orbit with the ophthalmic vein, and this latter opens into the cavernous sinus. This is a favorite route pursued by septic thrombi to the cavernous sinus in erysipelas about the root of the nose. The anatomic fact just mentioned regarding the angular vein accounts for the large size of this latter in intense cerebral congestion.

At birth the brain is relatively of large size. Its general form closely approximates that of the adult. The dura is tough, and its sinuses are in free communication with veins of the face, neck and scalp by means of rather numerous emissary veins. The pia mater is very delicate, a physical condition favoring traumatic cerebral hemorrhage at birth. The frontal lobe and the cerebellum are small. The sensorial areas are large, while the association centers of Fleschig are probably potential only.

SENSORIAL AREAS.

The sensorial areas are four in number. Each corresponds to a definite peripheral region of greater or less extent, and thus there is, as it were, a constant picture on the highly sensitized plate of the collective sensorial areas, projected by the terminal end organs of vision, hearing, smell and common sensation.

The retina corresponds to and projects a visual picture on the visual sensorial center in the cuneate lobe. The cochlea corresponds to and projects an auditory picture on the auditory center in the superior temporal convolution. The olfactory filaments correspond to and project an olfactory picture on the olfactory center in the anterior perforated space, trigonum olfactorium, uncus and collosal convolution. The nerve endings in skin, tendon, muscle, joint and viscera correspond to and project a picture on the somaesthetic area of the cortex—the largest and by all means the most important area, for in this all motor nerves originate and all nerves *of ordinary sensation end.*

According to Fleschig, two-thirds of the cerebral cortex is occupied by what he designates association centers, the remaining one-third being occupied by the sensorial areas previously enumerated. In very early childhood the sensorial areas are everything—the association centers are probably potential existences only. Later, with the dawn of intelligence and reason, the sensorial areas and association centers strive for cerebral supremacy.

The association centers are regarded as the part of the brain in which the higher intellectual functions are carried on, and they occupy considerable parts of the frontal, parietal, temporal and occipital lobes of the cerebrum. These centers are believed to exercise control over the sensorial areas. They are in abundant communication with the sensorial areas by association fibers, and thus receive from all parts of the body impressions which they are supposed to transform into consciousness and give definite form to impulses. The commendable product, then, of the association centers is mature judgment.

The association fibers acquire their sheaths of medulla and become functional only after education and intellectual effort have stimulated the different regions of the cortex to harmonious action. Different forces acting peripherally on retina, cochlea and sentiment surface are thus the stimuli of the sensorial areas. The result of cerebral stimulation, after having been transformed and unified by the association centers, is education. The manufactured product of the association centers, awaiting consignment and shipment, constitutes the visual, auditory, olfactory, muscular and other memories.

It would be illogical to assume that Nature, who delights in diversities, should dispose the sensorial areas and association centers with reference to child brain and adult brain according to a rule to which there could be no exceptions. Rather should there be overlapping or telescoping of the fields of the higher intellectual faculties in the adult brain and its juvenile prototype. In fact, observation would seem to confirm this view, and the investigations of Fleschig seem to point to its rational explanation in anomalous development of association centers.

Adult thought, application, acquisitiveness and mature judgment in a child is precocity. Inclination for childish things, destructive tendencies, extravagent expenditure of energy and resources, incommensurate with *physical strength and fortune respectively,* on the part of an adult, is evidence of an unbalanced mind. It must be assumed that as soon as all parts of the nervous system act in harmony—that is, as soon as the association fibers become invested by medullary sheaths—the brain is at its very best and, mechanically speaking, a perfect machine. If now we determine a table of doses of medicinal drugs capable of definite stimulation of sensorial areas, we shall have arrived at the proper dose for the healthiest human organism. Empiric practice has ascertained and recorded this table under the head of minimal doses. Let us also remember the table of adult doses of powerful drugs, and account anatomically for the great difference between infantile and adult toleration of drugs.

Instances are on record where minimal doses produced the most alarming toxic symptoms in adults, and rumor has it the cause of all this was an idiosyncrasy on the part of the patient. We are then driven to the conclusion that along with precocity and unbalanced mind should be recognized idiosyncrasy, a condition in which the adult sensorial centers have retained their pristine purity and responsitivity.

How are we to regard anatomically and physiologically a patient who, as experience shows, reacts only to heroic doses? In the same light in which we regard an engine which, when new, consumed ten tons of coal and two gallons of oil, but which, after twenty years' wear and tear, consumes a hundred tons of coal and twenty gallons of oil in a given time. What is the practical deduction regarding idiosyncrasy? Begin every new case on minimal doses, for who knows which patient may not be idiosyncratic. Herein lies the value of the family physician, for he knows the patient's peculiarities. The physician who has no time to understand the patient by confirming or disproving idiosyncrasy is a dangerous man to society and on a par with one who swears on skeletal evidences to sex, regardless of the scientific findings of the influence of contrary sexuality on the osseous system.

The precocious youth, the man of unbalanced mind, the idiosyncratic patient are victims of developmental processes. The first is not responsible for his scintillating wit, the second is not to be held accountable for his childish actions, the third should not be treated with indifference if he succumbs to a dose of medicine prescribed for his baby.

"When I became a man I put away childish things," were possibly as reliable a definition anatomically for man as jurisprudence can summon for insanity. Manhood can not be said to have begun until there is evidence of judgment, discretion and control of the impulses under trying circumstances; here childhood ceases; here have the association centers of Fleschig obtained a dominating influence over the sensorial areas.

979 Jackson Boulevard.

Glinical Reports.

SUTURE OF THE GREAT SCIATIC NERVE.

REPORT OF A CASE.*

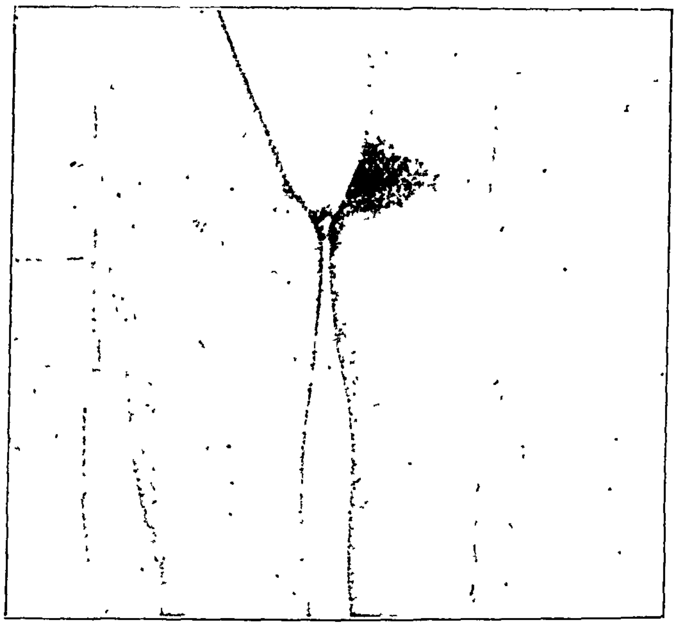
JAMES H. DUNN, M.D.
MINNEAPOLIS.

Wounds and suture of the great sciatic nerve are perhaps sufficiently rare to lend some interest to the following case:

J. S., an Irish farmer boy, aged 19, was struck by a scythe in the hands of a younger lad who was swinging the instrument on a level with his own waist. The lads were facing each other and the blade entered the outer side of the patient's left thigh, passed back of the femur, and the point emerged on the inner surface of the thigh just below the crotch. Between the points of entrance and exit the blade slipped under the skin and severed most of the muscles to the bone and divided the great sciatic nerve just below the gluteal fold. In removing the blade it was turned and the wound of entrance was slit downward some two or three inches.

The accident occurred July 18, 1898. Dr. J. B. White of Montgomery, some miles distant, was summoned hastily and found hemorrhage severe, and complete paralysis of motion and sensation in the sciatic distribution. He arrested the bleeding and dressed the leg as skilfully as possible, and on the next day brought him by rail to St. Mary's Hospital, where he arrived in the evening.

On the morning of July 20 we examined the patient together. Despite such antiseptic precautions as it had been possible to carry out at the scene of the accident, the wound was badly infected. After thorough cleansing I cut down on the nerve by the usual incision for stretching the sciatic at this point. (See illustration.) The severed ends were found retracted somewhat more than an inch. The ends were stretched, approximated and sutured by medium and fine catgut, three through-and-through sutures with the former and numerous sutures of the sheath with the latter. Several of the severed muscles were also sutured with catgut, and extensive drainage employed in all three of the wounds. The extremity was dressed and fixed in slight flexion. The wounds had all fully healed by August 20. A superficial slough the size of a dime on the posterior surface of the heel had appeared despite attempts to prevent pressure.



Scar of operation.

September 1 there had been decided improvement in sensation, possibly some motor improvement, and he was allowed about on crutches.

September 10 a rubber muscle was stretched from the toe of his shoe to a band below the knee, and he was sent to his home in the country. He wore the rubber muscle till the following May, at which time the improvement, both motor and sensory, was sufficient for him to resume his work as a farm laborer without any artificial appliances.

I had no opportunity to watch and record the progress of the case very accurately, but the patient reported by letter from time to time, indicating that some lesser improvement continued up to the end of two years, since which there is no perceptible change. That is to say, the improvement was progressively greater during the first year and tapered off, so to speak, during the second, when it ceased. The early decubitus healed quite promptly and never gave further trouble.

In the summer of 1901, I chanced in his neighborhood and went over to his place to see and examine him. I found him working in the hayfield. On taking off his rather dirty shoe and stocking I found he had a small perforating ulcer of the heel. This had come on during the past few weeks while working hard, and he thought it had been irritated by a wrinkle in the lining of his shoe. I secured a promise from him to visit me after his fall work was done, for a more complete examination than we could make in the field. In December, 1901, about three and one-half years after the accident, he appeared for examination, and Dr. W. A. Jones kindly examined him and made the following record for me: "There is some dulness of sensation in the external saphenous, external plantar and left half of the musculocutaneous, beginning at the ankle-joint region. Sensation above either nominal or slightly hyperasthenic; knee-jerk exaggerated in the left leg. Partial paralysis of the anterior tibial group only."

---

* Read before the Hennepin County Medical Society, March 3, 1903.

The right thigh measures 48.5 cm., the left 46.5 cm. The right calf measures 34.5 cm., the left 33.5 cm.

I have recently seen the patient, and his present condition, four and one-half years after the operation, is practically the same as last year, the ulcer has not healed, though a slightly better care of it has kept it at about a standstill. I believe it would heal if he were to lay up and attend to it properly. He has never done so for more than two weeks, during which time it showed improvement. It is a wonder to me that working as he does with dirty stockings and shoes, it has not proven more destructive and malignant.

The conditions for successful nerve suture were not good. The wound was forty-eight hours old, and badly infected. Prolonged drainage was necessary. The result is a perfect restoration of function, excepting decided paresis of anterior tibial group of muscles and consequent loss in extension of the foot, which, however, does not much interfere with his gait. Sensation is nowhere entirely lost, but slightly diminished on outer aspect of the leg, and quite decidedly so on the outer dorsal aspect of the foot. Trophic disturbance is indicated only by the characteristic perforating ulcer on the heel, which is about the size of a dime, very deep, reaching almost to the bone, and very indolent. The secondary factors of traumatism, infection and neglect, have been allowed full sway.

It has been a question in my mind whether it might not have been better to have first drained the wound, stamped out the infection and have made a secondary nerve suture, but I think not. The result is, I imagine, about an average good one. In the larger nerves some loss of function, especially motor or trophic, is, I believe, the rule.

A CASE OF RODENT ULCER.

J. C. O'DAY, M.D.

OIL CITY, PA.

The following case of ulcus rodens I believe is worth reporting, because of the extensive destruction to the face and the compatibility of a fair degree of health extending over a period of ten years. The history of the case is substantially as follows:

The patient is a male, aged 56, married, father of five children living and well. The family history is negative. The personal history is negative, except that prior to the onset of ulcer patient drank considerably.

Sixteen years ago a small pimple appeared over the right eye, becoming pustular and painful. The patient consulted a physician, who opened it with a needle, allowing the pus to escape. The margin now began to break down until the eyelid was threatened. Every effort of the physician to arrest the destructive character of the disease not only proved fruitless but seemed to aggravate it.

The patient, now thoroughly alarmed, sought the advice of several eminent surgeons of New York and Philadelphia, but in spite of every effort the disease progressed steadily, attacking skin, muscle, bone, eyes, nerves and all structures of the face. This continued six years, when the destructive tendency ceased. For the past ten years it has remained in about the same condition.

Examination shows the complete loss of the superior maxillæ, including all the soft structures up to the horizontal portion of the frontal bone. The tongue and remnant of the upper lip remain. In eating, he has his food minced and made into gruel with milk. This, with the aid of a spoon, he throws back on the base of the tongue, and it is readily swallowed. Words of the full vowel sound he utters distinctly, but with a peculiar horn-like pitch. He writes readily with slate and pencil, and in this way makes his wants known.

DR. GARCELON'S NINETIETH BIRTHDAY.

ITS CELEBRATION A PLEASANT FEATURE OF THE NEW ORLEANS SESSION.

Dr. Alonzo Garcelon, who is perhaps the oldest member of the Association, celebrated his ninetieth birthday at New Orleans May 6. Through the suggestion of Dr. L. Duncan Bulkley of New York, which was warmly seconded by others, Dr. Garcelon's birthday was not allowed to pass without a suitable memento from his many friends who were gathered at New Orleans. Over one hundred members each contributed one dollar, with which a loving cup was purchased. Subscriptions were limited to a dollar, so as to give a large number an opportunity to take part.

The presentation was a surprise to Dr. Garcelon; he had been informed that a few friends would come in, but he was not prepared for the surprise that awaited him. The loving cup was a beautiful present, on which was inscribed the following:

TO ALONZO GARCELON, M.D., ON HIS NINETIETH BIRTHDAY. IN LOVING REMEMBRANCE FROM SOME OF HIS FRIENDS IN THE AMERICAN MEDICAL ASSOCIATION, NEW ORLEANS, 1903.

Speeches were made by Drs. Bulkley, Lawrence, Bonifield, Gordon, Holton, Carstens, Montgomery, Marcy and others. They spoke of their great love for Dr. Garcelon and their pleasure in having him at the Association session. They held up Dr. Garcelon as a model medical practitioner, and likened him to a tall, native pine tree, standing sturdily as a monarch of the forest.

Dr. Garcelon, in his response, spoke very appreciatively of the favor shown him, and added a few words about the difference in medical conditions between his early days and the present.

After this enjoyable presentation a second took place. A handsome gold-headed cane was given to the former member of that body by the Board of Trustees, together with the Secretary and Treasurer of the Association. The inscription on the cane was:

DR. GARCELON. FROM THE MEMBERS OF THE BOARD OF TRUSTEES OF THE A. M. A., MAY 6, 1903.

Dr. T. J. Happel, chairman, made the presentation. He reviewed Dr. Garcelon's long career as a Trustee, and spoke in appreciation of the untiring labors he had performed and the great interest he always took in watching over the affairs of the Association and of THE JOURNAL.

Dr. Garcelon, in accepting the cane, said that with the permission of Providence he hoped he would have the pleasure of greeting the members of the Board of Trustees and of the Association many years more.

This event was a very pleasant feature of the visit to New Orleans for all those who took part. Dr. Garcelon is worthy of these honors and of many more, and the realization of this made the speeches very hearty and lent emphasis to all the eulogies.

Population Statistics in Germany.—The official figures for 1901 have just been published and are quoted in the "Allg. Med. Ct.-Ztg." for April 25. The proportion of births was 42.31 per 1,000 inhabitants in 1875, and has since been gradually declining to 36.79 in 1900, but in 1901 shows a slight rise to 36.89. The number of illegitimate births is the lowest for thirty years, 8.57, and in the manufacturing district of Westphalia only 2.60. The number of stillborn infants is also the lowest for many years, 3.13. During 1901 there were born in all 2,097,838, the proportion of girls to boys being 100 to 106.1. There were 26,127 twin births, 241 triplets and one case of quadruplets.

SATURDAY, MAY 16, 1903.

THE NEW ORLEANS SESSION.

The session of the American Medical Association just closed has been a success in every respect. The New Orleans arrangements were almost perfect, the general hospitality and feeling was most admirable, and the social functions passed off with delight to all. The Section meetings were above the average in the quality of the papers and the interest in the discussions; the business meetings disposed of matters which have long been a trouble to the profession. The President's Address and the orations have already been placed before our readers and need no comment. The attendance was far beyond expectations, and made it one of the largest sessions that the Association has ever held. The general spirit throughout was excellent, and we may say, altogether, that perhaps there has been no session that will leave pleasanter memories with those who attended it.

THE NECESSITY FOR REORGANIZATION OF OUR LARGE HOSPITAL SERVICES.

There is a well-known popular distrust of public hospitals—a distrust not always intelligent, certainly, and not always deserved. On the other hand, there are reasons for the failures of the great public hospitals which are not understood by the laity, though only too clear to the profession. From time to time, at more or less regular intervals, attention has been called through the public press to various irregularities, if not abuses, in the conduct of the public hospitals of our large cities. One point which is occasionally emphasized is the insubordination of internes, who have been especially charged with performing major operations, etc., in violation of long-established rules. According to the rules of the majority of such hospitals all surgical work, except minor emergency operations, must be performed, not by internes, but by a member of the staff, and internes are prohibited from administering anesthetics except under the supervision of some member of the staff.

This is excellent, but the truth is that too many of the public hospitals of this country suffer from a general lack of medical organization, and however sternly abuses may be dealt with, they will persist or recur so long as the present loose methods of hospital organization are continued. Many of these hospitals have at their head lay wardens or governors, who can not be expected to exercise authority in medical matters over attending men or internes. The visiting staff usually consists of a large number of physicians, appointed by the favor of the board of trustees, or of the president of the board. It consists in part of the most eminent physicians in town, who bestow on the hospital but little personal presence, and for the rest, of men who have eagerly sought these appointments for the prestige they could gain and whose presence in the wards is of doubtful value to the patients, and certainly fails to inspire the internes with respect. As this great unsalaried staff can not be held to strict service rules, the care of the patients actually devolves on the internes, who are brilliant young fellows, usually selected by severe competitive examination, but who too frequently cherish the delusion that they learn best by experimentation, untrammeled by the directions or interference of their elders.

Instead of welcoming the opportunity for receiving instruction afforded by the visits of attending men, the average interne resents their advice as an infringement of his rights. Superficially such hospitals are often spoken of as giving the best training to the interne. In fact, from a sternly scientific point of view, and quite without regard to the mere humanitarian considerations, this is a fallacy. No one would take a young man just graduated from a technical school and put him in charge of a great electrical manufacturing plant. Yet we take young men, fresh from a medical school, whose practical experience has been almost *nil*, and place them in sole charge of hospitals in which, the twenty-four hours round, desperate accident cases demand instant action, obscure ailments require the utmost diagnostic skill and operations involving life and death must be constantly performed. Does any one seriously believe that the young physicians, who in fact do a large part of this work alone and unguided, learn so much as they would under intelligent supervision? This state of affairs is known and deplored by the profession. The general public, however, which furnishes the material for these hospitals, does not know it, but is dazzled by the distinguished names at the head of the list of "attending men," and fancies them actually in charge.

Our large public hospitals need to be reorganized. They require a competent, specially trained physician as superintendent, whose appointment and tenure depend only on his efficiency and good faith, a small salaried, permanent medical and surgical staff, whose members can be held to responsible service and who will thus give the internes the instruction and discipline which is their due, and will secure to the patients the best possible care. The hospital services should be organized into definite and well-defined departments, each with its head, an adequate corps of assistants and residents.

In the majority of our large hospitals the term of service of an interne is nearly two years. By shortening this term to one year twice as many persons would be granted the opportunities for clinical experience that is offered to internes and which the fierce competition shows is valued most highly, and rightly so. The appointment of more permanent resident physicians and surgeons, as is now done in the best hospitals at home and abroad, would more than compensate for the more frequent change in the internes, and would give us properly trained men for the higher positions in the hospital services.

The time is unquestionably ripe for a vital change in many public hospitals if they are to fulfill their function as training ground for young physicians, and if they are to retain the confidence of laity and profession, which is their due. Nor should the task be very difficult. If the members of the staff are allowed their proper privilege of bedside clinics and are assured a reasonable tenure of office there will be no difficulty in securing the faithful service of the best men in the profession for the wards of our public hospitals.

FLIES AND TYPHOID FEVER.

The paper we published[1] a few weeks ago on "The Fly as a Carrier of Typhoid" acquires special emphasis in the light of two researches that have since been published in European journals. Levy and Kayser[2] have just reported some interesting observations on the duration of life of typhoid bacilli in stools that had not been disinfected, but had been thrown into a privy vault in the ordinary household routine. From such material they recovered a micro-organism which responded to all the usual cultural tests for the typhoid bacillus and agglutinated macroscopically with typhoid serum in a dilution of 1/5000. The feature that lends particular interest to this observation is that the full history of the infectious material was secured. In this instance the feces of a typhoid patient were first thrown, without disinfection, into a cemented vault and remained there during five winter months. The contents of the vault were then spread on the soil of a garden, and after the material had lain in this situation for fifteen days at winter temperature, the investigators succeeded in cultivating from the garden soil true typhoid bacilli. The authors call special attention to the fact, shown by this observation, that the contents of privy vaults containing typhoid bacilli may continue dangerous even after the lapse of months.

On the experimental side of the same question, particular interest attaches to an article by Ficker from the Hygienic Institute of the University of Berlin.[3] This investigator, after noting the fact that he had previously isolated typhoid bacilli from the bodies of flies caught in a house where eight cases of typhoid had occurred, proceeds to describe some interesting experiments made to determine the length of life of typhoid bacilli in or on bodies of flies that had been fed with infectious material. As a result of these experiments it appears that flies fed with typhoid bacilli are able to convey the microbes to objects with which they may come in contact for as long as twenty-three days after the feeding. Ficker's attempts to determine the region of the body in which the bacilli were located did not lead to altogether conclusive results, although he succeeded in isolating bacilli from the head, from the wings and from the legs in five days, and from the intestine nine days after feeding.

The independent investigations of these several authors will certainly tend to increase the suspicion with which the wanderings of the house fly are coming to be regarded. The protracted vitality of the typhoid bacillus in privy vaults, the long period during which the fly itself is capable of disseminating infection and the rapidly accumulating epidemiologic evidence all point to the importance of a source of infection, the very existence of which has until lately been insufficiently recognized.

LIVER SPOTS AND THEIR SIGNIFICANCE.

The popular name for certain yellowish or brownish yellow patches variously located in the skin has long been liver spots. Old school physicians have, as a rule, agreed with their patients as regards the designation of liver spots, though the newer school of physicians have been very much inclined to doubt the possibility of any connection between the liver and these localized pigmentations, and some have even deemed such connection entirely out of the question. In recent years much has been learned of their true character. When limited to the eyelids the patches of chamois or wash-leather appearance so familiar to the practitioner, have been called xanthelasmata. Other yellowish patches variously distributed over the body usually associated with some increase of the fibrous tissue of the corium, with some fatty degeneration of the overgrowth, and therefore deserving to have a hint of their tumorous character in their name, have been called xanthomata.

Under their new and ambitious names these patches seem to have lost much of their interest for the general practitioner, but undeservedly so, for they are a constitutional rather than a purely dermatic condition. A recent publication of the New Sydenham Society by Jonathan Hutchinson,[1] bears the significant title "Xanthelasma and Xanthoma, with Special Reference to Their Association with Functional and Organic Diseases of the Liver." Dr. Hutchinson has shown by the investigation of a number of cases that the coloring matter in the yellow fatty patches, known as xanthomata, is undoubtedly of liver origin. Not infrequently the spots are associated with jaundice or with some functional liver disturbance. Occasionally crystalline accumulations occur just over them in the skin, due to the precipitation of cholestearin which may persist for some time, or be reabsorbed.

[1] An atlas of illustrations of clinical medicine, surgery and pathology, compiled for the New Sydenham Society, Fasciculus xv., London, the New Sydenham Society, 1902.

Their occurrence should always lead one to examine carefully the condition of the patient's liver. The individuals who most frequently present "liver spots" are, in Dr. Hutchinson's experience, the so-called bilious subjects in whom functional liver disturbances are usually demonstrable without difficulty. The skin and hepatic conditions are frequently associated with severe headaches and migraine. Generalized xanthoma occurs, especially in diabetic subjects, and would seem to furnish some confirmation of the ideas of those who insist that the liver has a special function with regard to the metabolism of sugar in the system, which function is disturbed in diabetic patients.

Recurring liver disturbance, as Dr. Hutchinson points out, is prone to produce more or less significant changes in the eyelids. Three forms of palpebral skin alterations have been especially noted in this regard: First, a distinct pigmentation, more or less persistent, but prone to temporary increase in those parts of the eyelids now known as xanthelasma positions, that is especially around the inner canthus on the upper or lower lid. Second, the development of grouped comedones in these same positions with tendencies to subsequent pigmentations. Third, patches of yellow fatty deposit which constitute true xanthelasma. The old tradition of liver spots then and the associated etiology and significance are, it would seem, in spite of doubts in the matter, to be accepted and substantiated by twentieth century medicine.

ILLINOIS NURSES' BILL VETOED.

Among the governor's vetoes which have been announced is one by Governor Yates of Illinois, who has vetoed the trained nurses' registration bill; simply, as it appears, on the ground that the examining board was to be appointed from names selected by the Illinois State Medical Society. The governor objects to this as taking from the executive his prerogative, and, we might add, political perquisites. Why otherwise he should object to the assistance of a qualified organization in the selection of persons for a purely professional function is a little difficult to see from our point of view, though probably clear enough from his.

THE GERMAN REVOLT AGAINST CONTRACT PRACTICE.

The evils of contract practice and the extent to which the exploitation of doctors by workingmen's benefit societies has gone in some parts of the world are shown by a recent statement that a general action is going to be taken by the profession in Germany against employment by these sick-fund societies. In Germany, as in Great Britain, these societies have brought the average cost per call down to a ridiculously small amount. In the former country the average compensation per call is said to be only 4 cents. At Gera and Mülhausen the physicians have already refused to act for the societies, and in consequence these associations are obliged to pay the ordinary fees. Feeling is high, and at least one duel has been the result of the condition of affairs. We believe our brethren in Germany are in the right. We do not care to call the thing a strike, for this does not seem to be properly its name, though it has a resemblance to that movement so popular in this country at the present time. In England the same difficulties have been felt for a considerable time, and it will not be surprising if a general action similar to that of the physicians in Germany should be inaugurated there. In either case our confrères will have our best wishes for their success.

THE APPLICATION OF THE BIOLOGIC TEST FOR SPECIES TO BONES.

The above caption may suggest to those who remember the famous Luetgert murder case in Chicago, that it might have been possible to determine whether the boiled and alkali-eaten bones found in the vat were of human or animal origin. Experiments which Schütz[1] has been carrying out go to show that this differentiation could probably not have been made by the serum precipitation test of Wasserman. It is possible to determine the specific identity of bone only when a sufficient amount of albuminous material is attached to it, either in the marrow or in accidentally adhering muscles. For example, one wishes to know if a certain bone belongs to species A. An animal is immunized with the serum of a member of species A; an extract is then made of the bone in question, to get into solution albuminous bodies present in the marrow or adhering muscles. It is rather indifferent whether the material is fresh or dried. The extract is filtered and to the filtrate is added serum from the immunized animal. The occurrence of a precipitate indicates that the bone was from species A; if no precipitate, it was from some species other than A. Obviously bones in which the organic matter has been destroyed would be unsuited to the test. Schütz properly emphasizes the limited medicolegal value of this application of the precipitation test.

TYPHOID ON THE PACIFIC COAST.

The recent epidemic of typhoid at Palo Alto, the site of Leland Stanford, Jr., University, has excited some attention, but fortunately it appears to be associated with a very small mortality. Unlike the Ithaca epidemic it had no connection with the remissness of local authorities as regards water supply, and seems to have been entirely traced to one or two infected dairies. The comparative mildness of the epidemic as opposed to that of Ithaca is noteworthy, and in this connection we would remark on an editorial discussion of the subject in the *Medical Sentinel* for April, which antedated the Palo Alto epidemic. The editor finds from his observation and that of others that, while the disease is most unnecessarily and disgracefully present on the Pacific coast, the general mortality from typhoid is low, especially in Oregon, where his experience allows him to speak most authoritatively. There is a decided difference in this respect from the disease in the eastern states, though east of the Cascade range in the eastern portion of Oregon and Washington territory the condition is not the same. He has seen there several cases approaching the old typical typhoid of the eastern states, and the mortality appears, from such information as he has been able to obtain, distinctly higher than in the western part of the state. It would be especially interesting to know whether this same contrast prevails between eastern and western Washington. Whatever may be the cause of this difference, it has nothing to do with the locality of the bacillus. It is just as ready to defile the water supplies or to spread in other ways as in other sections of the country, but he suggests that some difference in the soil or water, while allowing it to grow and spread, diminishes its virulence, possibly by reducing its vitality from the onset. One possible cause is suggested, that is, the cooler temperature of the soil and ground water in Oregon, which is shown by the fact that in excavations almost anywhere eighteen or twenty inches below the surface, a temperature can be obtained at which butter remains firm and cream sweet all through the summer. Whatever may be the value of this fact as an explanation, the study is an interesting one and would indicate that the virulence of the typhoid bacillus is distinctly diminished in Oregon, and presumably in Washington and northern California. The subject is worthy of further careful investigation.

---

[1] Deutsche Med. Wochenschrift, 1903, p. 62.

Marriages.

Albert L. Stuttle, M.D., to Miss Pearl Jones, both of Williamsville, Ill., April 29.

Walter N. Miner, M.D., Calais, Me., to Miss Estella Delahay, at Baltimore, April 29.

Nathan Porter Colwell, M.D., to Miss Agnes Louise Peterson, both of Chicago, May 5.

James M. Anders, M.D., Philadelphia, to Miss Margaret Wunderlich, at Ardmore, Pa., April 29.

Martin H. Fischer, M.D., Berkeley, Cal., to Miss Charlotte Leonard of Chicago, May 6.

John Calvin Young, M.D., Roanoke, Ill., to Miss Elizabeth May Monser of Wenona, Ill., May 6.

Louis M. Friedrich, M.D., Hobart, Ind., to Miss Minnie Batterman of Chicago Heights, Ill.

Gustave Adolph Thiede, M.D., Baltimore, to Miss Mary MacCreager of Walkersville, Md., April 30.

Deaths.

Edwin Ellis, M.D. University of the City of New York, 1846, died at his home in Ashland, Wis., from paralysis, after an illness of a few hours, May 3, aged 78. Dr. Ellis was a pioneer of Northern Wisconsin, and was known as the "father of Ashland." He had seen the city grow from the primeval forest to its present magnitude, and was closely allied with every good feature of its growth, more especially with the school system. On account of his death the city offices and public schools of Ashland were closed on the day of his funeral.

James Conland, M.D. University of Vermont, Burlington, 1878, died at his home in Brattleboro, Vt., from nervous exhaustion, May 2, aged 52. He was a member of the state tuberculosis commission, and had served two terms in the state legislature. He was best known as the most intimate friend in the United States of Rudyard Kipling.

Eben J. Cutler, M.D. Cleveland Medical College, 1866, lecturer on surgical pathology and minor surgery in that institution; for two terms a member of the health board, and once police commissioner, died at his home in Cleveland, April 28, from pneumonia, after an illness of one week, aged 65.

Lucius C. Herrick, M.D. University of Vermont, Burlington, 1864, assistant surgeon in the Fourth U. S. Colored Cavalry in the Civil War, secretary of the Old Northwest Genealogical Society, died at his home in Cleveland, Ohio, April 30, after an illness of five days from gastritis, aged 63.

William Holbrook, M.D. New York University, 1848, surgeon throughout the Civil War; a member of the legislature in 1882, and Medical Examiner for East Hampden since 1877, died at his home in Palmer, Mass., from disease of the stomach of long standing, April 27, aged 79.

DR. JOHN HENRY MUSSER.

THE NEWLY ELECTED PRESIDENT OF THE AMERICAN MEDICAL ASSOCIATION.

Dr. Musser is one of a group of able young men whom the late Prof. Wm. Pepper gathered around him in the University of Pennsylvania—a group notable for ability, means and social standing; a group which Professor Pepper brought up in his own line of teaching, making them consummate diagnosticians and clinicians of unusual ability.

Dr. Musser was graduated from the University of Pennsylvania in 1877. He immediately started in practice in West Philadelphia, one of the poorer districts of the city, and soon built up an enormous practice. After a few years he associated himself in practice with his uncle, on the West Side, and on the death of his uncle succeeded to his extensive practice. During this time he gradually associated himself with his alma mater, beginning as instructor in medicine, his colleagues being Drs. Alfred Stengel, John K. Mitchell and the late Frederick A. Packard.

On the death of Professor Pepper Drs. Musser and Stengel were made professors of clinical medicine in the university, and Dr. Packard was made a trustee.

Later on Dr. Musser moved down town, and now has perhaps the largest family and consultation practice in Philadelphia. He has been physician to the Philadelphia and Presbyterian hospitals, and for many years a member and formerly president of the Philadelphia Pathological Society. He is one of the most modest and unassuming of men, but is surpassed by none in Philadelphia as a diagnostician and clinician.

Beside being the author and editor of standard works like his treatise on diagnosis, which is almost universally known to the profession, Dr. Musser has been for the last twenty years a contributor to periodical medical literature, both in this country and in Great Britain. His wide experience and clinical acumen have contributed a large amount of very interesting matter scattered through various journals which, if collected, would make volumes.

AMERICAN MEDICAL ASSOCIATION.

Proceedings of the Fifty-fourth Annual Session, held at New Orleans, May 5, 6, 7 and 8, 1903.

GENERAL MEETINGS.

Official Minutes.

May 5—First General Meeting.

The Association met at 11 a. m. in the Tulane Theater, and was called to order by the President, Dr. Frank Billings of Chicago.

Prayer was offered by the Rev. H. G. Davis, New Orleans.

Address of Welcome to the City by the Mayor.

Hon. Paul Capdevielle, mayor of New Orleans, was introduced, and delivered the following address of welcome:

Mr. President, Ladies and Gentlemen of the American Medical Association:

Only a few days ago I said to the Convention of American Manufacturers that, although many onerous duties were put on the mayor of a town like this, that of welcoming them to New Orleans was one which gave me nothing but pleasure.

The same idea occurs to me as I stand up before the body of learned and scientific men here assembled to-day. I owe it to the profession to add that except for the skill and devotion of the surgeons and physicians who came to my relief in a recent illness of the most serious character I would not have enjoyed the opportunity of meeting you on the present occasion.

The city of New Orleans is, and has always been, proud of its medical men. It has been the seat for many years of a medical college of the highest reputation.

The state of Louisiana, as its first and largest charity, has supported a great hospital in our midst, which was founded by Don Andres Almonaster y Roxas in 1786, where clinical instruction has been carried on with more practical advantages open to the student than are to be found anywhere else, perhaps, in the United States. Early in her history, the state of Louisiana became instructress in the science of medicine to her sister states of the west and southwest. The study of diseases peculiar to the climate has progressed in this way, with immense advantage to society and to science.

The problems of engineering involved in the drainage and sewerage of the great alluvial plain on which New Orleans is built, the settlement of plantations in different parts of the state, and the treatment of epidemic diseases have been constantly carried on with extraordinary benefits because of the success achieved in their profession by scientific physicians, benevolent men, the benefactors of their kind, who have practiced their calling in the interest of humanity.

In bidding you, as I do, a truly heartfelt welcome, I represent the feeling and sentiment of all our people. They ask your aid and counsel. They hope your deliberations will be marked by entire freedom of inquiry, as well as by harmony, and they look to the results, with assured confidence that these will inure to both private and public good. (Applause.)

Welcome to the State.

In behalf of Governor Heard, Gen. Leon Jastremski spoke as follows:

Mr. President and Members of the American Medical Association:

Called to the dedicatory exercises of the Louisiana Purchase Exposition at St. Louis, the Governor could not extend to you Louisiana's official welcome to the metropolis of the south. It is due to this circumstance that he deputized me to perform this very pleasing duty, which I regard also as a high honor. I would fail in my effort did I not say that in no state or country is the medical profession, or, better still, the calling of medicine, held in greater esteem or admiration than in Louisiana. It is the noblest and most ancient of all professions, dating back, according to the records extant, to the seventeenth century before the Christian era. To the land of the Pharaohs and the pyramids, to ancient Egypt is given the fame of inaugurating the records of the researches of medicine. In that remote era, and in succeeding ages, medicine was combined with theology and philosophy and was held in a reverence akin to superstition. The Jews, the Greeks, the Romans and afterward the Latins propagated the science throughout Europe and America. Amid the desolating plagues, in the camps of the Crusaders, the physician and surgeon went forth braving and enduring every hardship in pursuing his mission and acquiring knowledge. Then, as now, in his merciful work he made no discriminations between the king and the knight, the artisan and the peasant, the high born and the lowly, friend or foe. For him mankind has always been a vast brotherhood, at whose call for help he feels in duty bound to respond.

Some divine inspiration lifts the physician above the level of his fellow men and ennobles his nature. No danger, no loathsome disease repels him. He is found on the battleship, in the camp and the battlefield, attending the sick, the wounded and the dying. He is the presiding genius in the hospital and in the asylum for the insane. Everywhere he is the good samaritan, the tireless searcher for that knowledge that will more speedily cure, abate and prevent disease. For his science every decade is a decade of progress. He is of that army for which there are no hours set apart for repose. When others are resting from labors of the day, the physician is rising to bring hope and relief to the chamber of the sick. We can see him in the lurid conflagration at Moscow and in the appalling retreat of the Napoleonic army over the frozen and snow-covered steppes. We can see him in the column that marched to the relief of Lucknow, and with the famous expedition to Obdurman, across the burning sands. We descry him with the blue and gray at Gettysburg, at Shiloh, at Franklin and at Petersburg. All this is but a shadowy portrayal of the glories and the achievements of those knights of the medical profession, "without fear and without reproach," whose mission is to save, when other men, when nature itself, seek to destroy. Look the world over to-day, and you will be amazed at the progress that medical science has wrought. With its remedies it has mastered hitherto incurable ills, and by the wonderful operation of surgery it saves life and limb in cases that were helpless only a few years ago. By its discoveries in sanitation it has arrested the depopulation of cities and minimized contagion, so that the population of the world is increasing at a ratio never before attained.

You are here to impart to one another the additional knowledge that you have garnered separately for the expansion of the science to which you have devoted your lives. From your conferences, from your discussions, there will flow for mankind beneficences far more precious than heaps of gold.

For all the good that your profession has showered on mankind; for all the good that the American Medical Association has done in the past, and for all the good that it will do in the future, do I extend to you the most profound, the most friendly and the most loving welcome of the state of Louisiana. (Applause.)

Layman's Welcome.

Henry P. Dart, of the local Bar, spoke the welcome of the laymen as follows:

When I was notified to deliver one of the addresses of welcome on this occasion, I inquired who were the other speechmakers. The good doctor who was communicating with me said that the governor would deliver one on behalf of the state, the mayor one on behalf of the people of the city, and then, after some deliberation, he added: "and you may consider that you are going to appear on behalf of our patients."

While the prayer of the chaplain just delivered would indicate that you have also taken thought on the subject and have left your patients to the care of one who never fails, it is quite appropriate that I should convey to you the compliments of your patients and their congratulations that you are so harmlessly engaged on this fair morning in New Orleans. I almost regret to have to add that this city is so distressingly healthy that you would not be able to find substitutes to operate on in lieu of those you have left behind. (Laughter.)

I was further admonished that time was a factor in this address, inasmuch as it was known that 1,500 or more of the brethren would be in the audience, each with a thesis in his pocket and that delivery thereof was essential to the health of the author—a most unparalleled condition of affairs among people who usually do so little talking.

I was also warned to keep away from strictly technical subjects, leaving pulmonary complaints and disordered joints and things of that sort to the consideration of the fraternity. In fact, it was suggested that I should try to get on some ground of common understanding with the people at large, where the sects and divisions of the assemblage could do their thinking without undue effort to follow the speaker. This was, I thought, a delicate hint that while on this task my predecessors from my profession had exhausted the great question of medical jurisprudence, expert testimony, etc., and had exhausted their audience also.

It certainly is a great pleasure to participate in a gathering of so many of the best and strongest of a great profession, and it tempts one to wish that he could suggest something that would leave a lasting reminiscence in the minds of his hearers. As it is, I shall content myself with a mere note or suggestion of something which seems to me worthy of consideration in this wide and splendid life that you gentlemen lead.

From a layman's point of view, one of the most noteworthy contributions to an age full of noteworthy things is the modern hospital, which is supported entirely by the labors of the medical profession, without whose time, strength and money it would be impossible for its doors to open for the service which it professes.

Statistics show that these great institutions are managed under an expenditure and with as much care and pains taken as is found in the great industrial occupations of the day: and yet, marvelous to relate, the entire medical machinery of the same is furnished absolutely without cost. It is true that one or more men in each institution receive a stipend for their services, but that only proves the rule. All over the country these institutions are accustoming the people to the free services of the physician and surgeon. The rank and file of the community have learned that in these hospitals they will get the best of care, the best apparatus, and the best hand and brain that the profession can furnish, and they appreciate that they get all of this free; and so deep is their appreciation that I fear that they have fallen into the habit of looking on the members of the profession as walking eleemosynary institutions.

The hospital is built on private munificence. The state, it is true, here and there, as in the case of our own noble institution in New Orleans, makes an annual contribution; but this in no wise represents the great sum total of wealth that flows in and out of their portals. How long will the present system continue? Will the people of the coming generation and the members of your profession continue to serve as you have in the past, following literally the mandate of the Divine One to go forth and heal, taking thought neither of scrip or raiment, and depending, as did Elijah in the desert, on the ravens of chance and accident for your subsistence?

The mind is staggered when it contemplates the extent of the sacrifice made annually by the body of your profession in the service of humanity, by way of the hospitals of the country. No other sect or profession can point to an equal record. The preacher follows a philanthropic course by desire, and can not be blamed if his Maker gives him plenty to do while man fails to compensate him. The lawyer is fond of thinking that he is a great contributor to the public welfare without due compensation, paradoxical as that may seem to some of you; but it must be conceded that in the presence of this magnificent giving of the medical profession of their health, their strength and their time, there is no parallel in the world. It comes in on me as a real thing that this tremendous development on charitable lines is a marked characteristic of the times, and it suggests a tendency of the race. It is not accidental, it is an educated taste for which you are responsible, and it opens a great social question, whether or not some day the state will be forced to take it up as a state problem, and to manage charity in so far as healing and curing are concerned as a state institution. But I have not come here with a problem or a theme. I have merely thrown out a thought to fructify while you are bearing, like Atlas, the world of suffering and sorrow on your mighty shoulders.

Response to the Addresses of Welcome.

By the First Vice-President, Dr. J. A. Witherspoon of Nashville, Tenn.:

Mr. President, Ladies and Gentlemen:

I feel hopelessly unable to respond to the welcomes received this morning, especially on such notice as thirty minutes, were it not for the fact that I belong to and am a son of the south and know that every sentiment expressed by these gentlemen is a demonstration of the hearts of every citizen in New Orleans and Louisiana. (Applause.) I feel especially honored in being called on to respond to these addresses of welcome, in view of the fact that I live in the very shadow of the home of that grand old man, Andrew Jackson, who once, with his 3,000 Tennessee squirrel hunters, defended this fair city against the British. (Applause.)

So far as the hospitality at New Orleans is concerned, it was well illustrated by an Irishman, whose friend came to this country, and, having died here, his body was immersed in alcohol and sent back to his native country for burial, and his remark was, "Begorrah! The gentleman leaves in better spirits than he came." (Laughter and applause.) Even the dead in Louisiana are in good spirits.

The work of this state and of this city, headed by your remarkably intelligent State Board of Health, reflects credit on the medical profession, and it is a work that we can point to with pride. New Orleans has been visited so frequently by that particular scourge, decimating our people, blanching the faces of the bravest, so that the medical profession has sprung up as a unit to fight back those terrible diseases that knock at the citadel of our fair land. By the efforts of the Marine-Hospital Service and your State Board of Health we have now reached that proud position where we can say to that death-dealing monster—yellow fever—thus far shalt thou go and no further; you shall not wreck this fair land and take the loved ones from our bosoms, stop the commercial and agricultural interests of the entire people by your death-dealing poison. (Applause.)

We feel, in coming to New Orleans, that we come to one of the oldest and grandest and most hospitable places in this broad land. Many of us come from the east and north for the first time, and they have learned to look on our mountain peaks and our rivers as the most beautiful. It is even claimed that in some of our mountain districts we can stand on the very top of them and tickle the feet of the angels above. (Laughter.) But when we get down here to this temple in the universe, we feel very much like those who have not reached that state of married blessedness; likewise, we do not want to tickle the angels' feet, but we do like to tickle the fancies of some of them. (Laughter.)

Now, ladies and gentlemen, we thank you very much for the courteous and hearty welcome you have extended to us. We all feel at home. We have all left home to give our patients a chance to get well. I want to say to my good friend the lawyer, who has addressed us, that I feel very proud that one of his profession should have at last seen the beacon light and found out the medical profession stands on a pinnacle so high that law can only talk at it. (Applause.)

I have been called on unexpectedly to address you, and I feel very much like the old darky in Virginia who was carrying a turkey along under his arm, and a ventriloquist threw his voice to him: "What are going to do with me?" The old negro looked at the turkey, and said, "I'se gwine drop yuh right heah." (Applause.)

We thank you for your hospitality; we assure you that we feel perfectly at home, and, with these words, I leave the subject with you. (Applause.)

Report of the Committee of Arrangements.

Dr. Isadore Dyer, chairman of the Arrangements Committee, read the following report:

Mr. President and Gentlemen, Members of the American Medical Association:

I understand that a brief report is expected from the chairman of the Committee of Arrangements.

As soon as the medical profession of New Orleans was officially advised of the fact already published in the daily press that the American Medical Association was to meet in New Orleans, organization of the local members of the American Medical Association was effected.

The history of their work has been related in the Association JOURNAL. It remains only for the chairman to convey his high estimation of the individual services of the several sub-chairmen, who have been constant in their labors and earnest in effecting the result which we submit to you.

Whatever fault you may find must be attributable to our crudeness and newness to so stupendous a task; whatever credit or praise, to the work of every man on every committee.

The President's Address.

The First Vice-President, Dr. J. A. Witherspoon, at this juncture took the chair, and President Billings delivered his address. He selected for his subject, "Medical Education in the United States." [This appeared in full in THE JOURNAL, May 9, pages 1271 to 1276.]

TUESDAY, MAY 5—SECOND GENERAL MEETING.

The meeting was called to order by the President, Dr. Frank Billings, in the Carondelet Methodist Church, at 7:45 p. m.

Oration on Surgery.

The President introduced the orator of the evening, Dr. A. F. Jonas of Omaha, who delivered the Oration on Surgery. [This oration, on "Cancer and Immunity," appeared in full in The Journal, May 9, pages 1277 to 1284.]

Report of Committee on Portraits of Ex-Presidents.

Dr. J. R. Pennington, Chicago, chairman of the Committee on Portraits of Ex-Presidents, reported progress. He said that of the several portraits of ex-presidents in preparation for presentation to the Association, two have been received by the committee and will be formally presented by gentlemen who have been selected for that purpose.

Presentation of the Portrait of Dr. T. G. Richardson.

Dr. Edmond Souchon, New Orleans, presented the portrait of Dr. T. G. Richardson. In doing so, Dr. Souchon said:

It is indeed a great honor that was conferred on me to present the portrait of the first Louisiana President of the Association, Dr. T. G. Richardson, to the American Medical Association for its Hall of Fame. It is a labor of love, however, as I had the happiness to be intimately associated with this good and remarkable man, having been his prosector, his chief of clinic, his assistant also in almost all his operations in private practice and having been his friend and his fervent admirer.

It would require a book to tell of all his life and a pen much more gifted than mine to do justice to this noble man and his great work, but in the brief moments that are allotted me I can only recall the most salient traits of his life and achievements.

Dr. Richardson was born in Kentucky in 1827, and at the age of 18 he began the study of medicine under the direction of the great S. D. Gross, who was the professor of surgery in the Louisville Medical College, and the influence of Dr. Gross on his young pupil was magnetic and most beneficial. Dr. Richardson graduated in 1848 from the medical department of the University of Louisville, and he was immediately appointed demonstrator of anatomy in the medical department of that university. In the midst of his numerous labors he found time to write in several medical periodicals, and founded and edited, with Dr. Gross, in 1855, the "Louisville Review."

In 1856 he resigned his position as demonstrator to accept the chair of anatomy in the Pennsylvania College at Philadelphia, as Dr. Gross at that time had accepted the chair of surgery in the Jefferson Medical College, when they both founded in Philadelphia the "North American Medico-Chirurgical Review." Dr. Richardson was a remarkable dissector, as is evidenced by the numerous specimens he prepared at that time of his life and which now adorn the museum of the medical department of Tulane University, and he was the first one, I think, who used plain English names in his lectures and in his book on anatomy.

It was in 1858 that Dr. Richardson moved to this city to fill the chair of anatomy in the medical department of the University of Louisiana.

He had served as such but four years when the war broke out and, joining the Confederate Army, he became surgeon on the staff of General Bragg, during which term of service he was Medical Inspector of the Army of Tennessee, then Medical Director of the Department of North Carolina, and he was present and on duty at the famous battles of Murfreesboro, Chickamauga, Missionary Ridge and others.

After the war Dr. Richardson returned to New Orleans and was elected dean of the medical faculty. Then began, with the dark days of reconstruction, a most sickening and despairing struggle to prevent the college from falling into the hands of the carpetbaggers, and it required all the courage, determination and skill which he possessed to succeed, but he did ultimately succeed, and all agree that he was the only one who could have succeeded.

In 1872 Dr. Richardson became professor of general and clinical surgery in this college, succeeding the renowned and lamented Stone. It was in 1877 that Dr. Richardson was elected President of the American Medical Association, and presided at the annual session in Buffalo, N. Y., being the first president elected from Louisiana and still the only one.

His health began to fail him in 1886, and he was compelled to resign the chair of surgery in 1889. His illness lasted several years and, in spite of great sufferings, his thoughts were always with his beloved college, so much so that, together with his admirable and generous wife, he donated the sum of $100,000 for the building of a new medical college, the one now standing in our midst and bearing the glorious name of the Richardson Memorial.

Dr. Richardson died in 1892, before he could see the completion of the new college, having been dean for twenty years, a professor for thirty-one years, and having served the profession forty-four years.

Dr. Richardson was tall and stately, with a face of Olympian beauty, particularly as he grew older, with an appearance most impressive. It was reserved and somewhat cold, but it was only on the surface, because no warmer and generous heart ever beat in man's breast. This was most evidenced when he grasped your hand; then a magnetic current ran from him into you, and you felt at once that he truly was a good and earnest man; he was also calm, dignified, unostentatious; his sense of duty was intense, akin to worship, and the word responsibility was to him tremendous and overwhelming.

As a teacher he was surpassed by none, and as a surgeon he had the true mettle, as I could judge in many bloody and trying surgical operations.

He was at all times earnest, clear and forcible in his statements, and was most impressive in his teachings. His judgment was most clear and unerring, and he was modest beyond expression. In all my years of association with him I can not recall an instance when he lost the control of his temper, nor have I ever heard him utter a word of the mildest profanity.

His friendship was as true as steel. He never made any promise, but he had a good trait in that he would do things when you were in need that most unexpectedly showed that he was your friend indeed. Many have been the recipients of his bounty, and I am one of the living examples.

His love for brilliant plants and for exotic trees was most notable. He was unduly fond of children, who were instinctively drawn to him, and his devotion as a husband was the admiration of all who were admitted to his family life. He traveled all over the world, and specially delighted in exploring parts less known to most people.

He was most pure in thoughts, and hated hypocrisy, and last, but not least, his religious nature was most beautiful in its grandeur and sincerity, and many times it excited the envy of the less fortunate ones. When sickness and suffering struck him, he displayed a fortitude and submission to the will of God that was the admiration and wonder of those who saw him in the years of agony that tortured him before he died. A life-long friend of his, the Rev. Dr. Palmer, said that he was remarkable for the simplicity and directness of his character, due to the fact that he was pre-eminently self-contained.

Such was the man whose noble portrait will now truly adorn the Hall of Fame of the American Medical Association.

The General Meeting was then declared adjourned.

Wednesday, May 6—Third General Meeting.

The Association met at the Carondelet Street Methodist Church, and was called to order at 7:45 p. m. by the First Vice-President, Dr. Witherspoon.

Oration on Medicine.

Dr. J. M. Anders, Philadelphia, delivered the Oration on Medicine. [This oration, on "Social Conditions in America in Their Relation to Medical Progress and Disease," appeared in full in The Journal, May 9, pages 1284 to 1292.]

Presentation of Portrait of Dr. Hunter McGuire.

Dr. W. L. Rodman, Philadelphia, delivered an eulogy on Dr. Hunter McGuire, in presenting his portrait to the Association:

In Winchester, Va., Oct. 11, 1835, there began a life which was destined to be famous ere its first quarter of a century was rounded. The son of an eminent physician and surgeon, the talents of Hunter McGuire were fortunately dedicated to medicine. At the age of 20 he received his diploma from the Winchester Medical College, of which his father, Dr. Hugh H. McGuire, was one of the founders and professor of surgery.

Feeling the need of greater clinical advantages than were offered in Winchester, he matriculated in the fall of 1856 in both the University of Pennsylvania and Jefferson Medical College of Philadelphia, that city being then the mecca of southern students. His studies were soon interrupted by an attack of acute rheumatism, and he was compelled to return to his home in Winchester. In 1857 he was elected professor of anatomy in his alma mater, which position he filled one year.

In 1858 he was called to Philadelphia to join Drs. Francis E. Luckett and William H. Pancoast, a son of the famous surgeon and professor of anatomy of Jefferson College, in the conduct of a private quiz class for the benefit of students of that college. Some surprise was expressed that so young and unknown a man should be called to such an important teaching position. Dr. Luckett, when asked why he had chosen so youthful an associate, said: "Wait and see why I wrote for him." In accepting this call, we assume that Dr. McGuire was actuated by a desire to complete the studies interrupted by sickness two years before and to sit at the feet of the two great masters in surgery then at Jefferson College, Gross and Pancoast; the one the greatest surgical philosopher and teacher of his own or any time, the other the most consummate anatomist and the deftest operative surgeon of his day. Young McGuire, tall, spare, handsome, with manners somewhat unconventional and less gracious than many southern men possessed, yet always delightful, pleasing and entertaining as a companion, soon became the leader of the many southern students in this institution—in fact, their beau ideal. His success as an extramural teacher was remarkable and added much to the drawing ability of Jefferson College. Prior to this time a majority of the sons of wealthy southern planters who studied medicine had been going to the older and more renowned institution, the mother of medical schools on this continent, the University of Pennsylvania. The influence of Luckett and McGuire, both Virginians, was potential with southern men and drew many of them to the younger institution.

In December, 1859, sectional feeling became most bitter on account of John Brown's raid at Harper's Ferry, and when his body was brought through Philadelphia en route to his former home in Kansas for burial, the excitement reached white heat. It was then that young McGuire showed the elements of manhood and leadership which characterized him ever afterward. He left Philadelphia, marching at the head of 300 southern students, all armed, for the feeling was bitter and threats had been made against them, bound for Richmond, Va., where the study of medicine could be continued under more congenial environments. He advanced $2,000 of his own money, which he had saved as a quiz teacher, to pay the railroad fare of those students who were unable to do so. They were met in Richmond at the capitol square, where they were addressed in a stirring speech by Gov. Henry A. Wise. The citizens generally received them most cordially; the city council refunded the money spent in railway fares, and the Medical College of Virginia matriculated them without charge, most of the students remaining there, only a few going farther south to Atlanta and New Orleans.

McGuire received his second medical degree from this institution in the spring of 1860. In the fall of this year he then removed to New Orleans and established a quiz class in connection with the medical department of the University of Louisiana, now Tulane University. His stay in New Orleans was destined to be brief, for the following year South Carolina seceded from the Union and his native state, Virginia, was contemplating the same action. Loyal to her, brave and impetuous, he laid aside, for the nonce, the scalpel and listened to the stern alarums of war. He at once returned to Virginia, enlisted as a private soldier, marched to Harper's Ferry, and there he was commissioned as a surgeon and assigned to the command of Gen. Thomas J. Jackson.

In May, 1861, he became medical director of the Army of the Shenandoah, and later, when General Jackson assumed command of the First Virginia Brigade, he asked that Dr. McGuire be made his brigade surgeon. From that time on until the death of his illustrious commander he was closely associated with him personally and professionally. McGuire fully realized that he had been advanced beyond those much older than himself and, feeling that others questioned the wisdom of his very rapid advancement, he went to General Jackson and said that, rather than seem to be the means of doing an injustice to older men, he preferred tearing from his shoulders the insignia of office. Jackson, in his quiet, stern way, simply answered, "I appointed you." This must have meant to the young surgeon that it was an appointment of merit and not a personal preference.

No man ever had a keener insight into men's characters and was able to judge them instantly to a greater extent than Stonewall Jackson. This was, perhaps, the chiefest reason for his brilliant and meteoric career, and has caused him to be recognized by many as the greatest military genius produced by this, the greatest of wars. He saw in the tall, somewhat awkward young man qualifications of mind and heart on which he could unfalteringly depend in the many hard-fought battles and campaigns which yet lay before them. Never were trust and confidence better warranted. The youthful brigade surgeon was first to organize reserve corps hospitals in the Confederacy; this being done in the spring of 1862, during the Valley Campaign. About the same time he perfected the ambulance corps.

Greater, by far, than either of these, important works though they were, was his action early in the war requesting of his commander that eight Federal surgeons who had been captured be at once released on their own promise to endeavor to secure the release of an equal number of Confederate surgeons. This request was at once granted by General Jackson. This action, so manly, so lofty, so humane, at once attracted attention everywhere, and the practice of recognizing medical officers as non-combatants became practically universal in both armies. When he himself was captured in 1865 an order was promptly issued for his release by General Sheridan.

This is neither the time nor the place to speak of the valuable services rendered the Confederacy, from Manassas to Appomattox, by this able military surgeon. Without disparagement to others, it will be generally granted that he was the most conspicuous, useful and, perhaps, the greatest medical director in either army during the Civil War. He was, of course, fortunate in serving under such commanders as Lee, Jackson, Ewell and Early and could not have enjoyed the confidence of all as a man, a surgeon and a soldier to the extent that he did unless possessed of unusual qualifications. As a result of his large and varied experience as a military surgeon, he was asked to write the chapter on gunshot wounds for Holmes' System of Surgery, and has ever since been recognized as an authority on the subject throughout the civilized world.

His two most distinguished patients during the war were General Jackson himself, on whom he did an unsuccessful amputation, and a young lad, 18 years of age, who was shot with a minie ball midway between the knee and hip, which shattered the bone badly and which caused McGuire and the other surgeons to advise hip-joint amputation. The young fellow protested; McGuire telegraphed to his father, who came from Lynchburg, and, as a result of the entreaties of father and son, an effort was made to save the limb. McGuire removed nearly all of the femur, little dreaming that his patient would recover. He did so, however, and, though a cripple in body ever since, he is a giant in intellect, and to-day represents Virginia in the United States Senate.

After the close of the war in 1865, utterly broken in fortune, but not in spirit, Dr. McGuire settled in Richmond, Va., to begin the practice of medicine. He was soon called to the chair of surgery in the Medical College of Virginia, made vacant by the death of Dr. Charles Bell Gibson. The same qualifications which had made him so successful in war brought him immediate recognition and success in civil practice. As a teacher he was clear, lucid and forceful. He soon became famous as a lithotomist, lithotripist and ovariotomist; patients coming to him from all parts of the south.

The year after he settled in Richmond he married Miss Mary Stuart of Staunton, Va., daughter of Secretary of the Interior Stuart under President Fillmore. She must have been a beautiful girl, judging from her appearance and gracious bearing as a mature woman when she officiated, in 1892, as the wife of the President of the American Medical Association. Her manners were most charming. They were a typical southern couple and unusually devoted to one another. As a result of this union there were nine children, two of them physicians, Dr. Stuart McGuire of Richmond and Dr. Hugh McGuire of Alexandria. The former, who was associated with his father in work, now fills his professorship and is a man of fine ability and one of the well-known surgeons in the south.

Dr. McGuire continued to fill the chair of surgery in the Medical College of Virginia until 1878, when faculty differences caused him to retire. Later on, however, he was made emeritus professor of surgery. He devoted himself, for several years, entirely to his private practice, which was so large as to compel him to have a private hospital, which he built in 1883 and called "St. Luke's Home for the Sick." In 1893 Dr. McGuire organized and caused to be incorporated the University College of Medicine, the doors of which were opened in October and which at once proved to be a success. From the beginning it was a three-year graded school and up to the time of his death he was its professor of clinical surgery.

Dr. McGuire was no ordinary man; he was an original thinker and can be truly considered a "pathfinder" in medicine and surgery. His large experience as a military surgeon had taught him the futility and hopelessness of treating gunshot wounds of the abdomen by the expectant plan and many years before the first laparotomy was performed for such injury he advised it and predicted that the time would come when gunshot wounds of the abdomen would not be treated by opium and a "do-nothing" policy. To McGuire and Sims, who were the first in America to advise surgical intervention in gunshot wounds, and to Kinloch, the first to put into practice this teaching, we are indebted for the advancement which has brought at least 50 per cent. of recoveries where hitherto nearly all had been lost. I speak advisedly, I think, for then the large, round, leaden ball was used which, moving with slow velocity and usually carrying in with it foreign material of septic nature, was practically always fatal. Great as is the word of speech, the word of action is greater, and we must, therefore, accord to Kinloch the greater credit. Perhaps McGuire was best known for his work in the treatment of enlarged prostate, and his original operation of establishing an artificial urethra after a suprapubic cystotomy. At this time, when prostatectomy and Bottini operations are the fads of the day, it is well particularly to emphasize the good work done by McGuire in this direction. There is no doubt that many cases have been made to enjoy a comfortable existence by his operation which would have inevitably perished had either a prostatectomy or Bottini operation been performed on them.

Dr. McGuire had many civic and professional honors conferred on him; being in turn president of the Richmond Academy of Medicine; one of the organizers and president of the Virginia State Medical Society; president of the Southern Surgical and Gynecological Association; vice-president of the International Medical Congress; president of the American Surgical Association, and President of the American Medical Association in 1892. He had many honorary degrees conferred on him by different institutions, notably Jefferson College, where he wrought as an extramural teacher in anti-bellum days.

He was not a voluminous writer, and yet he wrote singularly well and has left several productions which will endure. As a companion he was most charming and entertaining. As a raconteur he had few equals, and could tell the southern darky stories in a way that no one else I have ever seen could do. He was easily the foremost citizen of Richmond and was so recognized.

His life closed with the nineteenth century, which had produced so many great men and had seen surgery advanced in such a remarkable way.

McGuire was fortunately young enough to accept and practice antiseptic surgery from its birth, and it was due to this fact that he, along with Yandell of Louisville, his intimate friend, could do better work than any of their great predecessors had done.

No part of America has contributed more to surgery than the south, and the impartial critic must accord Hunter McGuire a high place, even in such company as McDowell, Dudley, Brashear, Sims, Battey, Stone, Smythe, Eve and Yandell.

In the spring of 1900, while driving from his house to St. Luke's Hospital, he was seized with acute bulbar paralysis. Unable to speak, he motioned his driver to hurry on to the hospital, then, suddenly changing his mind, he directed him to drive to his home. Here he lived surrounded by his faithful wife and children for six months, unable to articulate, but at times able to drive and walk about. He had been in ill health for several years, being a great sufferer from gout, and this, we know, prevented him from attending the various associations of which he was a member. He was so missed at the Denver meeting that at the banquet of the Section on Surgery it was unanimously voted that he be sent a telegram conveying the love and best wishes of the Section.

On September 19 he fell asleep, hearing, let us believe, the voice of his great commander calling, "Comrade, I am waiting. Cross over the river and rest under the shade of the trees."

Now, Mr. President, in the name and by the request of his family, I take pleasure in presenting the Association with the portrait of the surgeon, the soldier, the gentleman, Hunter McGuire of Virginia.

A motion was made and carried thanking the donors of Dr. Richardson's and Dr. McGuire's portraits, after which the meeting was adjourned.

Thursday, May 7—Fourth General Meeting.

The Association met at 7:30 p. m., and was called to order by the President

Dr. William H. Welch, Baltimore, delivered the Oration on State Medicine.

After this the Association adjourned.

Friday, May 8—Fifth General Meeting.

The General Meeting was called to order at 12:15 p. m., in the Carondelet Street Methodist Church.

The Secretary presented a brief report of the work accomplished by the House of Delegates, and announced the officers elected. [See proceedings of the House of Delegates, page 1383.]

President Billings invited the Vice-Presidents present to the platform, and among those who responded were Drs. G. C. Savage, C. Lester Hall and George F. Jenkins.

Turning to the Vice-Presidents, President Billings said: I congratulate the Association, and I congratulate you, on the election to the high office you occupy for the ensuing year.

President's Closing Address.

In closing this meeting, I desire to say a few words to the members of the Association who listened to my long address at the opening, and to the House of Delegates, who have borne with me patiently for four days. In addition to what I said last year when inducted into office, I wish to say that I appreciate the honor which this Association did me in electing me its President. I have endeavored with might and main, truthfully and faithfully, to do the work which the office entails. If mistakes have occurred, they have been mistakes of judgment, and my ability was not sufficient to prevent them. But I can assure you that my efforts have always been in earnest.

Again I thank you most heartily for the honor you have done me. (Applause.)

Dr. Charles A. L. Reed, Ohio, moved that when the Association adjourns, it does so to meet in adjourned meeting on Tuesday, May 12, 1903, at 2 p. m., at 103 Dearborn avenue, Chicago. Carried.

On motion of Dr. McMurtry, the General Meeting then adjourned.

HOUSE OF DELEGATES.

Proceedings at New Orleans, May 4, 5, 6, 7 and 8, 1903.

Official Minutes.

Monday, May 4, First (Informal) Meeting.

The House met informally at the Carondelet Street M. E. Church, and was called to order by the President, Dr. Frank Billings, Chicago, at 3 p. m.

The President stated that the object of the informal, but unofficial, meeting was to listen to reports of committees, which were published, and refer them to committees, thus shortening the work which would come before the House at future meetings. He said, further, that last year the Business Committee recommended that the House of Delegates hold its first meeting at 8 o'clock the evening preceding the regular meeting of the Association, and a resolution to that effect was accordingly adopted. Therefore, at 8 o'clock this evening the House could transact regular business, if there was no objection.

The report of the Board of Trustees was called for, and passed, as the board was not ready to present its report at this time.

Report on Prophylaxis of Venereal Diseases.

Dr. Henry D. Holton, Brattleboro, Vt., chairman of the Committee on Prophylaxis of Venereal Diseases, read the report of that committee. [This was printed in full in The Journal, May 9, pages 1317 to 1319.]

Dr. William T. Bishop, Pennsylvania, moved that the thanks of the House be extended to the committee; that the committee be continued, and granted the privilege of appointing additional members, if deemed necessary, to carry out the recommendations submitted in the report. Seconded.

Dr. H. Bert Ellis, California, moved to amend that the Board of Trustees be instructed to furnish funds necessary to carry on the work of the committee. Seconded by Dr. Hill, Wisconsin.

The amendment was accepted; whereon Dr. J. N. McCormack, Kentucky, moved as a substitute that this important matter be referred to the Business Committee, and subsequently be brought before the House with the recommendations of the Business Committee.

The substitute was seconded and carried.

Business Committee Reports.

The President called for the report of the Business Committee.

Dr. Harold N. Moyer, Illinois, chairman, said the committee had not been able to have a formal conference in reference to matters to come before the House; therefore, a definite or formal report could not be made at this time. However, he was prepared to say that the committee had agreed on this plan: That the House of Delegates shall meet at 9 a. m. in official executive meeting, and it is hoped that half an hour or an hour devoted to each meeting will dispose of the business, permitting an adjournment of the House as a whole, and passing then to a committee of the whole, for the discussion of such special topics as might be assigned from the House. An afternoon meeting of the House could be held, if necessary. This, in brief, was the substance of the committee's report, so far as it relates to advising the House as to the conduct of its business. Dr. Moyer said the Business Committee would make its formal report at a subsequent meeting.

On motion of Dr. A. E. Baldwin, Illinois, the matter of selecting a member to respond to the addresses of welcome was left to the President.

On motion, the House adjourned, to meet at 8 p. m.

MONDAY, MAY 4, SECOND MEETING.

The House reconvened at 8 p. m. and was called to order by the President.

Dr. H. N. Moyer, Illinois, chairman of Business Committee, said the committee had considered the status of this meeting, and that it was in conflict with the Constitution. Therefore, anything done would have no legal effect. The committee urged, however, that such business as could be gotten through be taken up, and, as a preliminary to that, unanimous consent to the consideration of business at this time should be obtained, otherwise the committee feared the House could not proceed.

On motion of Dr. William T. Bishop, Pennsylvania, unanimous consent was granted and the business proceeded.

Dr. Moyer, speaking for the Business Committee, said that, according to a resolution adopted last year, all new business is referred to the Business Committee without debate. He, therefore, suggested that the resolution of last year be carried into effect this year.

Dr. H. O. Walker, Michigan, moved the readoption of the resolution of last year. Carried.

Dr. Moyer said the Business Committee recommends that when this meeting adjourns, the House meet at 2 p. m. tomorrow.

Dr. H. A. West, Texas, moved that the recommendation of the committee be concurred in. Carried.

Dr. Moyer stated that the Business Committee recommends that the following business come before the meeting: 1. Report of Board of Trustees. 2. Report on Association Medal. 3. Report on Senn Medal. 4. Report of the Committee on Scientific Research. 5. Report of Committee on Public Health.

It was moved that the order of business be that outlined by the chairman of the Business Committee. Carried.

The Secretary called the roll of delegates, and a quorum responded.

Report of the Board of Trustees.

Dr. T. J. Happel, Tennessee, chairman of the Board of Trustees, then read the report of the board. [This appeared in full in THE JOURNAL, May 9, pages 1309 to 1317.]

On motion of Dr. H. O. Walker, Michigan, the report was accepted and the recommendations contained therein referred to the Business Committee.

The President called for the report of the Committee on Association Medal, which was passed.

The President called for the report of the Committee on Senn Medal, when Dr. M. L. Harris, Illinois, a member of the committee, said the committee was not yet ready to make its report. He asked for further time, which was granted.

Report of the Committee on Scientific Research.

In the absence of Dr. Alfred Stengel, chairman of the Committee on Scientific Research, the Secretary read the report of this committee, as follows:

Early in the fall, the committee advertised in the pages of THE JOURNAL and through other medical journals, that five grants of $100 each would be made to persons applying for the same who could show sufficient training and opportunity to warrant the making of a grant. Considerable correspondence resulted and applications were received from a number of physicians. From these the committee has selected, as most deserving, the following:

Dr. Newton Evans and Dr. F. J. Otis, Battle Creek, Mich., for work on "Systemic Infection with Blastomycetes."

Mr. G. F. Ruediger, Rush Medical College, Chicago, for work on "Virulent Streptococcus."

Dr. J. T. Moore, Galveston, Texas, for a study on the "Latency and Relapses of Malarial Fever."

Dr. H. E. Wetherill, Philadelphia, for an "Experimental and Clinical Study of Sweat Secretion."

ALFRED STENGEL, Chairman.

On motion of Dr. E. E. Montgomery, Pennsylvania, the report was referred to the Board of Trustees, inasmuch as it involves the appropriation of money.

The report of the Committee on Public Health was called for.

Dr. H. A. West, Texas, a member of the committee, said he had not heard from the chairman. He suggested that the report of this committee be postponed until the members of the committee had held a meeting.

The suggestion was accepted, after which the House, on motion, adjourned to meet in the Council Chamber of the City Hall at 2 p. m., Tuesday.

TUESDAY, MAY 5, 1903—THIRD MEETING.

The House of Delegates met at 2 p. m. and was called to order by the President.

The Secretary called the roll, and a quorum was present.

The Secretary read the minutes of the previous session.

On motion of Dr. McCormack, the minutes were adopted as read.

Dr. Joseph D. Bryant, New York, took the chair, and President Billings delivered the following:

Message of the President to the House of Delegates.

The year just completed has been a remarkable one in the history of the Association.

This, the second meeting since the plan of reorganization was adopted, finds something like eighteen states practically completely organized on the plan outlined by the Committee on Organization. This committee will make a detailed report, which I am sure will be most gratifying to you.

THE FUTURE REORGANIZATION PROGRAM.

The Board of Trustees has told you of the necessity of commanding the service of an organizer who may visit the different parts of the country and personally explain to the physicians of county societies and of state associations the plan of organization.

The Trustees found an ideal man in the person of Dr. J. N. McCormack, chairman of the Committee on Organization. He is especially fitted for the task. His strong personality, backed by the wisdom of a Solomon, a superlative tact and the thorough knowledge of the subject which three years or more of work and experience in reorganization has given him, enable him to do the work as could few, if any, others.

We must not rest content with reorganization where we are. The work has just begun. To carry it on and complete it the

Association must spend money. If properly expended it will return to us in some form of compensation and prove a good investment.

I believe the Association should, therefore, recommend to the Board of Trustees the continued employment, if he will consent to spare the time to do it, of Dr. McCormack as an official organizer of the Association.

THE RUSH MONUMENT.

Eighteen years ago the Association met in New Orleans. At that meeting a resolution was adopted to appoint a committee for the purpose of obtaining funds with which to erect a monument at Washington, D. C., to Benjamin Rush. It was believed by the maker of the resolution that the estimated necessary sum of $50,000 with which to erect the monument could be raised by subscription in two or three years. It is not necessary to recall to you the fact that you have had a Committee on Rush Monument since that time. This year the committee decided to use the funds already in hand and carry out the plans of the Association begun so long ago.

The committee will maks its report in detail. I only desire to say that the monument will be erected on a suitable site in Washington, on or before the end of 1903. I would, therefore, suggest to you that it would be eminently desirable that the next meeting of the Association be held at Washington, when the Rush monument could be dedicated with proper and imposing ceremonies.

BUREAU OF MEDICINES AND FOODS.

During the year it became necessary for your president to appoint a Provisional Committee on the Establishment of a National Bureau of Medicines and Foods.

The necessity of the standardization of foods and drugs is one which probably all will admit who have considered the subject.

Just what part this Association may safely and judiciously take in the management and control of a corporation which shall attempt to control food and drug adulteration of the country is one on which the Provisional Committee will report.

MEMBERSHIP FOR STOMATOLOGISTS AND PHARMACISTS.

One of the best conducted sections of the Association is that of Stomatology. Its efficient secretary has served continuously for sixteen years. This section is threatened with annihilation, since the plan of reorganization was adopted. This should be obviated by the adoption of the by-law proposed last year which would enable the reputable dentists who have a degree of D.D.S. to become associate members of the Association.

The same condition appertains to the graduates in pharmacy, and similar action should be taken with them.

The mention of graduates in pharmacy reminds me that the Section on Materia Medica, Pharmacy and Therapeutics has advanced far beyond its scope. Two years ago it was proposed that the therapeutics be dropped from that section and that all papers relating to the treatment of disease be transferred to the Section on Practice of Medicine. This should be done. The proper designation of the present Section on Materia Medica, Pharmacy and Therapeutics should then be the Section on Pharmacology. The papers then offered in the section should be limited to the very broad and interesting field designated under the above-named title.

DETERMINATION OF ANNUAL SESSION PLACES.

Each year the Association is forced to precipitately consider the subject of the next place of session. The result is that the place has not been always chosen wisely.

The Association would be materially aided in choosing the next place of meeting if it should make the Committee on Transportation and Place of Session a permanent one.

It would be well to have the chairman of this committee so situated that he would be in touch with the Secretary and with The Journal of the Association.

Those cities which desire to have the Association on any specified year should be obliged to place the invitation in the hands of the committee at least three months in advance of the meeting next preceding that to which the Association is invited. The committee should then collect data as to facilities of travel, with rates, hotel accommodation and rates, and the opportunities afforded in the way of halls and other suitable meeting places by the city sending the invitation. The committee would then be able to report definite and desirable data to the House of Delegates. This would enable us to choose the next session place without fear of overcrowding in hotels, of inadequate railroad facilities, poor or widely separated halls for section meetings and extortionate charges in hotels and elsewhere.

MEMORIAL TO MAJOR REED.

Last autumn the American medical profession and this Association lost one of its most useful and illustrious members. The death of Major Walter Reed was a national disaster. His work in the investigation of yellow fever stamped him as an original scientific experimenter. His methods were resourceful, bold, brilliant and decisive. Like all true scientists, he was modest, quiet, retiring and superbly humane. He was a captain of science, but only we of the profession can know what his work has done for humanity and commerce.

To those whom his work will be of the greatest benefit his death passed unnoticed; Congress voted his widow a paltry pension.

This Association can not afford to let Major Reed's death pass unnoticed. His memory should be perpetuated by some suitable memorial to be erected at Washington or at his grave in Arlington.

Just how the Association should proceed in the matter of aiding in the erection of this memorial is a question which I shall leave to the delegates of this house.

THE BUSINESS PROCEEDINGS.

Gentlemen, the membership of the House of Delegates is composed of the picked men of the membership of the affiliated state associations. You have been selected by your state societies because you possess attributes which make you better qualified, perhaps, than your fellow members to carry on the legislative business of the Association. The members of the Association, therefore, expect work of the highest order from you. Your acceptance of the office of delegate implies that you will give the proper attention to the duties of a delegate. This means a prompt report at the opening of each session and continuous attendance at the general meetings and on the committees to which you may be appointed. This means a sacrifice of time from attendance on the scientific work of the sections and the social pleasures here offered you. This sacrifice may be minimized for most of you by promptness and fidelity in attendance on meetings and especially if we shall consider all questions which come before us in a rational, liberal minded way. There should be no quarreling here. We may differ in opinion and still retain possession of our better natures and sounder judgment. Your president is not a parliamentarian. There may be men on this floor who are versed in all the methods of blocking action and confusing the presiding officer.

This I mention as an indication of my own limitations and not that I expect to meet opposition on this floor. I bespeak your indulgence and patience, and I assure you of my desire to conduct your business fairly and with dispatch.

On motion of Dr. Wall, Buffalo, the address was referred to the business committee.

The next order was the report of the Secretary, which was read.

Report of the Secretary.

Chicago, May 1, 1903.

To the Members of the House of Delegates, American Medical Association:

Gentlemen:—At the last meeting of this Association I was instructed to obtain, as far as possible, correct information in regard to the qualifications of every physician who now claimed membership in the American Medical Association, and to drop all who are not eligible according to our laws.

For various reasons it was impossible for me to systematically start at this work before December. On commencing it, I found that the task was much larger than might have been anticipated, for the reason that but few of the state societies had a knowledge of those who were members of affiliated societies in the state and, consequently, eligible to membership in the American Medical Association. Hence, in spite of a large amount of correspondence, we have not been able to more than half complete the work of verifying our list of members.

In those states that have reorganized, the problem is an easy one, but in the other states it is decidedly difficult, although I think in a very short time the work will be completed.

At the beginning of this work there was very little coöperation on the part of the officers of some of the state societies, and under these circumstances it was thought best to let the matter drop until more interest was shown. At the present time I am glad to say that in nearly every instance a disposition is shown to co-operate with the American Medical Association, not only in this matter but in others also. The state societies are beginning to appreciate that the work of the Association in this regard especially will redound to their benefit and usefulness.

Up to the present time 146 members have been dropped on account of not being members of affiliated societies. Aside from these, between 125 and 150 were at first not qualified, but have now associated themselves with affiliated societies or have made application for membership. These have been retained on the list of members of the American Medical Association, believing that it is better to take more time and thus give those an opportunity who desire to remain members of the Association and to co-operate in the work of organization.

The experience thus far has convinced me that this enforcement of the by-laws of the Association will prove to be of benefit, not only to the county and state societies, but to the American Medical Association.

A very large number have an idea that the laws in regard to membership now being enforced are new conditions, and protests have been made for this reason. When it is shown that these rules and regulations governing membership are not new, and that the only change is that they are now being enforced, criticisms on the action of this Association are disarmed.

The membership of the Association during the year ending Dec. 31, 1902, increased about 1,450. Since January 1 there has been an increase of 920. In other words, during the last few months, since the enforcement of the by-laws, the membership has increased faster than ever.

MANILA MEDICAL SOCIETY.

I received a letter from Dr. Richard P. Strong, secretary of the Manila Medical Society, on Dec. 15, 1902, in which he said:

> I have been directed to forward to you a certified copy of the constitution of the Manila Medical Society, and to request of the American Medical Association recognition and affiliation.

I submit herewith the constitution forwarded.

UNITED STATES INDIAN SERVICE.

Dr. Z. T. Daniel, of Rose Bud, S. D., a member of the Association and connected with the United States Indian Service, wrote, under date of March 30, 1903, asking that the rules regulating membership of the officers of the Army, of the Navy and of the Marine-Hospital Service should also apply to the United States Indian Service.

DELEGATE TO THE CANADIAN MEDICAL ASSOCIATION.

April 2, 1903, I received a letter from Dr. George Elliott, general secretary of the Canadian Medical Association, dated April 1, 1903, in which he said:

> The president of the Canadian Medical Association, Dr. Walter H. Moorhouse, London, Ont., desires me to extend an invitation to the American Medical Association to appoint a delegate from your Association to the thirty-sixth annual meeting of the Canadian Medical Association, which is to be held this year in the city of London, Ontario, on the 25th, 26th, 27th and 28th days of August.

Respectfully submitted,
GEORGE H. SIMMONS, Secretary.

On motion of Dr. Bishop, Pennsylvania, the report was referred to the Business Committee.

Report of Business Committee.

The House then listened to the report of the Business Committee, presented by Dr. Moyer, Illinois, chairman, on the order of business of the day. The committee further reported that when the House adjourns, it adjourns to meet at 9 o'clock to-morrow morning.

On motion of Dr. Wall, Buffalo, the report of the Business Committee was adopted.

Dr. Moyer, Illinois, speaking further for the Business Committee, said that the committee had considered the report of the Board of Trustees and other sundry matters referred to it. He read the committee's recommendations that are detailed below.

Trustees and Journal Praised.—The committee desires to express its appreciation of the skilful management of the property of the Association by the Board of Trustees, and to commend the scientific position which THE JOURNAL has achieved under the direction of the Board of Trustees.

Dr. William T. Sarles, Wisconsin, moved that the report of the Business Committee be adopted as presented. Seconded.

Dr. William T. Bishop, Pennsylvania, moved to amend by taking the report up seriatim. Seconded.

The motion as amended was carried.

New Button Design Adopted.—Dr. Moyer then read the following: The committee recommends that the new design for the official button be adopted.

On motion, this section of the report was adopted.

Incorporation Postponed.—The next item was in regard to the matter of national incorporation. On this subject the committee reported: In common with the Board of Trustees, the committee regrets the difficulty attending national incorporation, and feels that this should be kept before the Association as an ultimate goal, but that no further action on this subject should be taken at this meeting.

It was moved and seconded that this recommendation be adopted.

Dr. Lester, New York, moved as an amendment that a committee be appointed to get the advice of the best legal talent in the United States as to whether the Association could be incorporated under an act of Congress or not, and report at the next annual session to the House of Delegates.

The amendment was seconded and accepted. After some discussion, Dr. Wall, Buffalo, moved as an amendment to the amendment that the House authorize an expenditure of $500 for the purpose of obtaining legal opinions which may be submitted one year from now. (Not seconded.)

The original motion as amended was then put and carried. In the discussion it was understood that no money shall be expended for this purpose.

As Dr. Lester did not specify the number of the committee in his amendment, Dr. A. E. Baldwin, Illinois, moved that a committee of three be appointed by the President to consider the matter of national incorporation. Seconded.

Dr. Stevens, Pennsylvania, moved to amend that a committee of five be appointed instead of three and that no two members of the committee shall be from the same state.

The amendment was accepted and carried.

Trustees' Report Adopted.—Dr. Moyer said the committee recommends the adoption of the report of the Board of Trustees as a whole, as amended. On motion, this recommendation of the Business Committee was concurred in.

Report of Committee on National Bureau of Medicines and Foods.

Dr. E. Eliot Harris, New York, presented the report of the Committee on the Establishment of a National Bureau of Medicines and Foods.

On motion of Dr. J. N. Jackson, Missouri, the report of the committee was referred to the Business Committee.

Report of Committee on Revision of Code of Ethics.

Dr. E. Eliot Harris, New York, chairman, presented the report of the Committee on Revision of Code of Ethics and offered the following resolutions:

> *Resolved*, That the Special Committee on Revision of the Code of Medical Ethics unanimously recommends that its report be referred to an enlarged committee, consisting of this Special Committee and one delegate from each state not already represented on the Special Committee, to be appointed by the President.
>
> *Resolved*, That the enlarged committee give a hearing to any member of the Association who may desire to appear before it at the St. Charles Hotel on this, Tuesday, evening at 9 o'clock.

Dr. Harris, Illinois, moved that the report of this committee and its resolutions and any amendments pertaining to this subject and now ready to be offered, be referred to the Business Committee for action.

Dr. Wall, Buffalo, moved that the report of the committee be received and that the recommendations be adopted. Seconded.

Dr. Charles A. L. Reed, Ohio, offered a substitute for the report of the committee, and moved its adoption.

It was moved that the substitute report for the Special Committee on the Code of Eth the resolutions offered and the report of the Special Committee, be referred to the Business Committee.

Dr. Reed's resolution was accepted by Dr. Harris, and the report was so referred.

[See report of enlarged committee on page 1379.]

The President called for the report of the Committee on Sections and Section Work.

Dr. L. S. McMurtry, Kentucky, chairman, said that as only two members of the committee were present he requested the privilege of making the report to-morrow, if compatible with the business before the House.

There being no objection the request was granted.

Report of the Committee on Medical Education.

The report of the Committee on Medical Education was read by Dr. Arthur D. Bevan, Illinois, chairman of the committee.

Mr. President and Members of the House of Delegates:

Your Committee on Education, consisting of Floyd W. McRae, Atlanta, Ga.; Rudolph Matas, New Orleans; R. A. Marmion, U. S. Navy, Washington, D. C.; C. A. Daugherty, South Bend, Ind., and Arthur Dean Bevan, chairman, respectfully submit the following report:

THE ORIGINAL PURPOSE IN FOUNDING THE AMERICAN MEDICAL ASSOCIATION.

We desire first to call attention to the fact that the American Medical Association was formed for the purpose of elevating the standard of medical education in this country. The original call of the Medical Society of the State of New York, which led to the formation of the American Medical Association, was as follows:

> WHEREAS, It is believed that a national convention would be conducive to the elevation of the standard of medical education in the United States, and
>
> WHEREAS, There is no mode of accomplishing so desirable an object without concert of action on the part of the medical societies, colleges and institutions of all the states:
>
> *Resolved*, That the New York State Medical Society earnestly recommends a national convention of delegates from medical societies and colleges in the whole Union to convene in the City of New York on the first Monday in May, 1846, for the purpose of adopting some concerted action on the subject set forth in the foregoing preamble.
>
> *Resolved,* That a committee of three be appointed to carry the foregoing resolution into effect.

These delegates met and adopted the following, which resulted in the formation of the American Medical Association:

> First. That it is expedient for the medical profession of the United States to institute a national medical association.
>
> Second. That it is desirable that a uniform and elevated standard of requirements for the degree of M.D. should be adopted by all the medical schools in the United States.
>
> Third. That it is desirable that young men before being received as students of medicine should have acquired a suitable preliminary education.

Your committee find, therefore, that the American Medical Association was founded for the purpose of elevating the standard of medical education in the United States. Your committee believe that this is still one of the important functions of the American Medical Association. In the course of years this object has been largely lost sight of, probably because with a loosely organized body it was difficult to accomplish satisfactory results in this direction. With the new reorganization of the Association into a compact representative body, representing the medical profession of each county and state, your committee feel that the American Medical Association has become the best national instrument to supervise and elevate medical education.

THE IMPOSSIBILITY OF NATIONAL LEGISLATION.

Our form of government in this country, giving to each state the right to control its own affairs subject simply to the limitations imposed by the constitution of the United States, makes it impossible to obtain medical legislation from the national government. A national supervision of some sort is obviously a necessity. In the absence of national governmental control, we believe that national effort to elevate medical education can be made most effective through the agency of the American Medical Association. Your committee believe that it is the duty of the American Medical Association to undertake such national supervision of the matter of medical education, and that it has the influence sufficient to make its regulations effective.

THE NEED OF ELEVATING THE STANDARD.

Your committee find that the standard of medical education in the United States is very uneven, representing the highest and lowest types, as compared with such civilized powers as England, France and Germany. As a whole, it is distinctly lower than in those countries and lower than it should be to meet the requirements of medical science in the present stage of development. With the advances which are rapidly making medicine a science, the study and practice of medicine are becoming year by year important and weighty functions in every community.

Medicine demands a better order of intellect and better preparation than is possessed by the poorer part of the men who are to-day entering its ranks in America. The other great world powers, our competitors in commerce, arts and science, demand in their medical men as a minimum requirement a preliminary education equal to or more than our best high schools, and then five years of medical study. Such requirements are none too high, and we in this country can not much longer afford to remain satisfied with anything in medicine short of the best. We can not, however, obtain such a marked advancement in requirements at once or in one step. Such an advance must gradually be brought about. Many agencies are now actively at work elevating medical education in this country. The great universities with medical departments have some of them advanced their requirements to a higher point than that obtained anywhere else in the world; the examining boards of many states have done much to elevate medical education by their demands; the work of the Association of American Medical Colleges has also been a factor of importance.

The great work, however, of bringing the entire body of the American medical profession up to an acceptable standard will be accomplished not by university presidents or state legislatures, or associations of medical schools, but by the medical profession itself, through its county, state and national associations.

A PLAN SUGGESTED.

The first step in advancing medical education to be taken by the American Medical Association should be the adoption of an educational requirement for membership—i. e., the fixing of a minimum requirement both as to preliminary education and as to medical education. This, in the opinion of your committee, should be:

First. As a preliminary requirement a high school education —i. e., sufficient to enable the student to pass the examinations for entrance to our standard universities.

Second. A four-year medical course of at least seven months in each year. That requirement should become effective within five years and apply to graduates of 1908 and after that date, sufficient notice being thus given to all medical schools of the country to enable them to change their curricula to meet these requirements.

DETAILS OF CARRYING OUT THE PLAN.

As to the best plan of making this effective, your committee believe that this should be accomplished in the following way:

After voting to adopt such educational requirements, the House of Delegates should inform the officials of each state medical society that the American Medical Association has adopted such educational requirements for membership, and suggest that such officials notify each county medical society in their state, with the request that the educational requirement adopted by the American Medical Association be made a part of the constitution of each county medical society. Your committee believes that such action would be practically unanimously taken, and in this simple way the first and longest step in the way of supervising and elevating medical education by the American Medical Association could be accomplished. Because of the amount of work, especially correspondence, made necessary to see that such educational requirement is made a part of the constitution of each county medical society, your committee would suggest that a considerable degree of permanence be given to the committee on education, and that sufficient funds be appropriated to enable such committee to effectively carry on their work.

Your committee would suggest that the educational committee consist of five members serving five years, one to be appointed each year; the first committee to be appointed one for one, one for two, one for three, one for four and one for five years; thereafter, one new man appointed each year.

Your committee would suggest that a sum not exceeding $5,000 each year be appropriated to carry on the work of the committee on education, a part of this to be paid a salaried assistant secretary selected by the committee. We would recommend that the Secretary of the American Medical Association be made *ex officio* a member of this committee and that headquarters of this committee be provided in the office of The Journal Building of the American Medical Association.

THE COMMITTEE'S PROGRAM OF ACTION.

Your committee further suggests that it be the duty of the committee on education to:

1. Secure the adoption of the educational requirements determined on by the American Medical Association by each state medical society, and assist the state medical societies in securing the adoption of these educational requirements by each county medical society.
2. To see to it that all medical schools are thoroughly informed of the educational requirements of the American Medical Association and to urge on such schools as do not demand such requirements the necessity of doing so.
3. To inform themselves as to the requirements and character of work done by each medical school.
4. To inform themselves as to the laws governing the practice of medicine in each state and as to the manner in which these laws are being enforced.
5. To inform the state examining boards and licensing bodies of the educational requirements of the American Medical Association and urge those whose requirements are below those of the American Medical Association to adopt the higher requirement.
6. To inform themselves on all matters pertaining to medical education.
7. To carry out the instructions of the House of Delegates in matters of medical education.
8. To make a full report of their work to the House of Delegates at each annual meeting.

Believing, as did the founders of this Association, that one of the most important functions of the American Medical Association is the elevation and supervision of medical education in this country, your committee ask for your careful consideration of this subject, and urge prompt and effective action along the lines suggested.

On motion of Dr. H. O. Walker, Michigan, the report was referred to the Business Committee.

Amendments to the By-laws.

The next order was the consideration of amendments offered at the last meeting.

Dr. Moyer, Illinois, read the original section of Article 4, Chapter 7 of the By-Laws, regarding the Committee on Nominations. He also read the proposed substitute for it, as follows:

> Nominations for officers shall be by informal ballot in the House of Delegates, unless otherwise ordered, by a majority of the delegates present when such nominations are made. Twenty votes shall be necessary to nominate them, and after the nominations are made, the balloting shall continue until some nominee has received a majority of the votes present. After the second formal ballot the nominee receiving the lowest number of votes shall be dropped, and so on in each successive ballot until an election is had.

On motion of Dr. McCormack this amendment was adopted.

On motion of Dr. McCormack other pending amendments were referred to the Business Committee.

The President called for the report of the Committee on Organization.

Dr. McCormack, Kentucky, chairman, asked for further time, as the committee was not ready to report, which was granted.

Report of the Committee on Association Medal.

Dr. L. S. McMurtry, Kentucky, presented a verbal report of the Committee on Association Medal. He said the chairman of the committee who had preceded him had resigned the chairmanship at the last meeting of the Association. For some reason the committee has not been able to select a prize, and he did not know how successful the committee has been in having applications presented to them. Some time after the meeting at Saratoga he was notified by the Secretary that the President, Dr. Wyeth, had honored him with the chairmanship of the committee. He said there was nothing specific in the act creating the committee as to the conditions required of the essays that are presented or the line of investigation to which the essays shall be directed. There are no specific restrictions under which the award is made, and the committee has no authority under the law, by which it was created, to proceed in the matter. He had not been able to confer with his associates on the committee. He asked that the committee be empowered to go forward and to arrange specifications and details to have the work done, and to present the specifications in The Journal as soon as practicable after the meeting, so as to be able at the next meeting to present material that would be worthy of the award.

On motion of Dr. Vance, Kentucky, the committee was continued and given the power requested.

Report of the Committee on Senn Medal.

Dr. M. L. Harris, Illinois, a member of the Committee on Senn Medal, whose report was called for at this time, said he had been asked by Dr. Dunn, the chairman, who was unavoidably absent, to report the finding of the committee. The members of the committee had carefully considered all of the papers presented to them, and had unanimously found that no paper presented had met the requirements imposed on the awarding of the medal.

On motion the report was accepted.

Report of Committee on Rush Monument.

Dr. Henry D. Holton, Vermont, presented the report of the Committee on Rush Monument Fund as follows:

Philadelphia, May 1, 1903.

To the President and Members of the American Medical Association.

Gentlemen: Your committee on the Rush Monument Fund reports as follows:

At the meeting at Columbus, Ohio, the resignation of the former chairman, Dr. Albert H. Gihon of the U. S. Navy, since deceased, was accepted, and Dr. J. C. Wilson of Philadelphia was appointed to the chairmanship of the committee. The committee at that time consisted of Dr. Henry D. Holton of Vermont and the chairman.

At the meeting at Atlantic City, on the request of the members of the committee as then organized, its membership was increased to five. Drs. Frank Billings of Chicago, Wm. L. Rodman of Philadelphia, and L. D. Bulkley of New York were added to the committee.

The funds in the hands of the treasurer of the committee at that time amounted to about $10,000. In addition to this there was $2,000 contributed by the profession of Pennsylvania, in the custody of Dr. Davis of Pittsburg, and a small sum amounting to about $60 in the custody of the treasurer of the Philadelphia County Medical Society.

Personal efforts were from time to time made by members of the committee to increase this fund, but without success, and various plans having the same end in view were discussed by the members of the committee. Among these were:

First, a further appeal to individual members of the Association and to the profession at large. It was felt that this plan would not prove acceptable and would probably not be attended by success.

Second, it was suggested that the committee should directly appeal to the Trustees of the American Medical Association for an appropriation to this fund, but conference with some members of the Board of Trustees made it evident that such an appeal could not be granted.

Third, and finally, your committee considered the question of appealing to the Congress of the United States for additional funds. This plan was abandoned because it seemed to the committee best that the memorial to Rush should be the direct gift of the profession to the people.

Several months ago it was determined by the committee to ascertain whether or not a suitable monument could be procured with the funds in hand, now amounting with interest approximately to $15,000. The result of negotiations on this subject were satisfactory and the committee has entered into a contract with the Henry Bonnard Bronze Co. of New York City, and through them with Louis R. Metcalfe, Esq., as architect, and R. Hinton Perry, Esq., as sculptor, to erect, on the site originally designated by the Secretary of the Navy on the elevation in the park opposite the U. S. N. Museum of Hygiene, 25th and E streets, Washington, D.C., a monument that shall be satisfactory to the committee and approved by the National Sculpture Society of New York City. This action on the part of your committee has been unanimous and has received the unofficial endorsement of a number of the members of the American Medical Association. It is hoped by the committee that it will receive the favorable consideration of the Association as a body and that the monument to be erected will be creditable as a work of art, an impressive ornament to the locality selected for it and an inspiring memorial of the illustrious member of our profession whose career it commemorates.

Those who have undertaken the work have given reasonable assurance that the monument will be completed and ready for unveiling early in the autumn of the current year.

In conclusion your committee offers the following resolution: That a sum not exceeding $500 be placed to the credit of the committee to defray expenses incidental to the unveiling of the monument, any portion of this sum not being expended to be returned to the treasury of the Association.

All of which is respectfully submitted.

Henry D. Holton, Treasurer.
J. C. Wilson, Chairman.

HENRY D. HOLTON, TREASURER.

In account with Rush Monument Fund.

June 1, 1902—

Cash on hand	$ 219.35
Funds invested in stocks and bonds	12,200.00
Dividends received	417.00
Dividends due June 1, 1903	200.00
Due from Pennsylvania Medical Society	2,00.00
Interest	
	$15,036.35

It was moved by Dr. John B. Roberts, Pennsylvania, that *the report be accepted and referred to the Board of Trustees* with the recommendation that funds be appropriated as asked for. Carried.

Appointment of Enlarged Committee on Revision of Principles of Ethics.

Dr. Moyer, speaking on behalf of the Business Committee, in reference to the report of the Committee on Revision of Code of Ethics, said that the committee recommends that the report, together with the substitute proposed and all matters pertaining thereto, be referred to the larger committees, consisting of a representative from each state that is not now represented, to be appointed by the President, said committee to meet immediately after the adjournment of the House of Delegates for organization.

Dr. McCormack, Kentucky, moved that the larger committee be composed exclusively of members of the House of Delegates. Seconded and carried.

The President thereon appointed the following committee:

Alabama—W. H. Sanders.
Arizona—I. W. Craig.
Arkansas—J. A. Dibrell.
California—C. G. Kenyon.
Colorado—J. N. Hall.
Connecticut—C. S. Rodman.
Delaware—G. W. Marshall.
Dist. of Columbia—G. M. Kober.
Florida—R. D. Murray.
Georgia—F. W. McRae.
Illinois—Frank Billings.
Indiana—Edwin Walker.
Indian Territory—B. F. Fortner.
Iowa—Samuel Bailey.
Kansas—J. E. Minney.
Kentucky—Ap Morgan Vance.
Louisiana—Rudolph Matas.
Maine—S. C. Gordon.
Massachusetts—H. E. Marion.
Michigan—T. A. Felch.
Minnesota—William Davis.
Mississippi—J. C. Hall.
Missouri—J. N. Jackson.
Montana—T. J. Murray.
Nebraska—A. B. Anderson.
New Hampshire—I. J. Prouty.
New Jersey—Charles J. Kipp.
New Mexico—J. F. McConnell.
North Carolina—E. C. Register.
North Dakota—E. M. Darrow.
Ohio—C. A. L. Reed.
Oregon—
Pennysivania—John B. Roberts.
Rhode Island—John Champlin.
South Carolina—Geo. R. Drau.
South Dakota—W. J. Matum.
Texas—H. A. West.
Utah—A. C. Ewing.
Vermont—D. C. Hawley.
Virginia--Stuart McGuire.
Washington—P. W. Willis.
West Virginia—L. D. Wilson.
Wisconsin—W. T. Sarles.
Wyoming—Geo. W. Johnston.

Money for Committee on Scientific Research.

Dr. E. E. Montgomery, Pennsylvania, reported on behalf of the Board of Trustees in regard to the resolution submitted in connection with the report of the Committee on Scientific Research. He said the Board of Trustees moved that the money should be appropriated when the report has been made and accepted by the Association, said report to be the property of the Association.

On motion of Dr. H. Bert Ellis, the report was adopted.

Dr. McCormack moved, in accordance with an announcement made in The Journal, that to-morrow afternoon be set apart for receiving the reports of delegates in the matter of organization in their respective states, and that it be made the special order, after the reading of the minutes.

On motion the House of Delegates then adjourned until 9 a. m. Wednesday.

Wednesday, May 6, Fourth Meeting.

The House of Delegates met at 9:10 a. m. and was called to order by the President.

A quorum was present when the roll was called.

The Secretary read the minutes of the previous meeting, which were approved.

Dr. Moyer, Illinois, on behalf of the Business Committee, reported the order of business for the meeting, and on motion of Dr. Sarles, Wisconsin, the report of the committee was adopted.

Education Committee's Report Accepted and Ordered Printed.

Dr. Moyer, Illinois, reported that the Business Committee had considered the report of the Committee on Education, and begged leave to report as follows: The committee recommends the adoption of the report, and that it be referred to the Board of Trustees, with the endorsement of the House of Delegates.

Dr. Ellis, California, moved the adoption of the report of the Business Committee. Seconded.

Dr. Edwin Walker, Indiana, moved to amend that the report be received, referred to the Board of Trustees, and be printed for circulation. Seconded.

The motion as amended was carried.

Action Postponed on Bureau of Medicines and Foods.

Dr. Moyer stated that the committee had considered the *report of the Provisional Committee* on the Establishment of a National Bureau of Medicines and Foods, and felt that the report, as submitted, was so vague in its provision, so meager in detail, that it recommends it be not adopted. The committee *recommends that the whole matter be referred to the legis*lative committee, to report at the next annual session.

It was moved that the recommendation of the Business Committee be concurred in. Seconded.

After some discussion, which was participated in by Dr. Jones, California, and Dr. Moyer, Illinois, Dr. Harris, Illinois, moved that the matter be recommitted to the original Provisional Committee on the Establishment of a National Bureau of *Medicines and Foods.*

This motion was seconded and carried.

Manila Medical Society Admitted.

Dr. Moyer said the Business Committee had considered the Secretary's report and begged leave to report on certain items, as follows: That the Manila Medical Society be accorded representation on the same basis as a state or territory, providing that their organization be extended to include the Island of Luzon, and such other portions of the Philippines as may organize local medical societies.

It was moved and seconded that the recommendation of the Business Committee be adopted. Carried.

Department of the Interior To Be Represented.

Dr. Moyer stated that the committee recommends that the Secretary be instructed to correspond with the Interior Department, and advise the House of Delegates at the next annual session, with a view of according this service specific recognition.

On motion, the recommendation was concurred in.

Delegate to Canadian Medical Association.

The Business Committee recommends that the President appoint a delegate to represent the American Medical Association at the thirty-sixth annual meeting of the Canadian Medical Association. On motion, the recommendation was adopted.

Secretary's Report Adopted.

The Business Committee recommends the adoption of the report of the Secretary.

It was moved that this recommendation of the Business Committee be adopted. Carried.

Dr. McCormack Praised.

The Business Committee recommends the expression of appreciation of the services of Dr. J. N. McCormack, in reorganizing the profession; it further recommends to the Board of Trustees, a continuation of those services, if Dr. McCormack can be persuaded to continue with the work.

On motion, these recommendations were adopted.

Permanent Committee on Place of Annual Session.

With reference to the item contained in the President's address, in regard to the place of holding the next meeting, the

Business Committee recommends that it be referred to the Committee on Transportation and Place of Session, and that this committee be made a permanent one with the duties suggested by the President.

It was moved that this be adopted. Carried.

Regarding that part of the President's address concerning papers offered in the Section on Materia Medica, Pharmacy and Therapeutics, the Business Committee recommends that it be referred to the Committee on Sections and Section Work.

On motion, the recommendation was concurred in.

Committee on Memorial to Major Walter Reed.

The Business Committee recommends the appointment of a committee of three of the House of Delegates to co-operate with other bodies looking toward placing a suitable memorial in Washington, D. C., commemorating the scientific achievements of Major Walter Reed.

On motion, this recommendation was adopted.

Consideration of Standing of Dental and Pharmaceutic Members.

In reference to the Section on Stomatology, Dr. Moyer, speaking for the Business Committee, said there were two amendments to the Constitution which were proposed last year, and which the Committee had elaborated, and which it recommended for adoption.

Dr. John B. Roberts, Pennsylvania, moved that the amendments be taken up. Carried.

Dr. Moyer then read the following:

Amend Section 6, Article 3, with a section, as follows:

> Dental Associate Members: Dentists who hold the degree of D.D.S. from a reputable dental college, and who are members of recognized local and state dental societies, may be admitted as associate members, on recommendation of the officers of the Section, subject to approval by a majority vote of the members of the Section.

The Business Committee moved, as an amendment to Section 7, Chapter 1, of the By-laws, the following:

> Pharmaceutic Associate Members: Pharmacists who are recognized graduates of pharmaceutic schools or colleges and are members of the American Pharmaceutical Association, may be admitted as associate members, on recommendation of the officers of the Section on Materia Medica, Pharmacy and Therapeutics, subject to approval by a majority vote of the members of the Section

It was moved that the amendment recommended by the Business Committee in regard to associate dental members be adopted. Carried.

It was moved that the amendment in reference to associate members of pharmacy be adopted. Seconded.

Dr. Hill, Wisconsin, moved, as a substitute, that action on the amendment of the Business Committee, in reference to associate members of pharmacy be postponed until the committee had received a recommendation from that section. Seconded and carried.

[Both of the above amendments were revised later.]

Minor Amendments to Constitution.—Under the head of proposed amendments, Dr. Moyer said the first amendment is in regard to Section 1, Article 4, of the Constitution, as follows: After the word "service" at the end of paragraph, add

> And (4) the officers of the Association.

He said the Business Committee recommended as a substitute for that this wording, to follow the word "service":

> The Board of Trustees shall be members of the House of Delegates, but shall not vote.

On motion of Dr. McCormack, this recommendation was adopted.

The next amendment relates to Article 8, Section 4, as follows: Strike out all after the word "to" in the second line, and insert:

> The office of President or Vice-President.

The Business Committee recommended the adoption of this amendment, and on motion the recommendation was concurred in.

A third amendment was with reference to Section 3, Chapter 9, of the By-laws. The committee reported, as a substitute, that the wording of this section read:

> Each Section shall have the privilege of sending to the House of Delegates one delegate.

On motion of Dr. McCormack the amendment was adopted.

The next amendment related to Section 5, Chapter 3, of the By-laws.

The Business Committee recommended that this section be repealed.

It was moved that this recommendation be adopted. Carried.

Quorum of the House Defined.—The next amendment related to Section 10, Chapter 3, namely, to strike out the word "majority" and insert the word "twenty-five" in its place. The section would then read:

> Twenty-five members composing the House of Delegates shall constitute a quorum for the transaction of business; provided, that at any *adjourned session* of any annual meeting, ten members shall constitute a quorum.

It was moved that the amendment be adopted. Seconded.

Dr. Bishop, Pennsylvania, suggested that the amendment read:

> Twenty-five delegates representing states.

Dr. Wall, Buffalo, offered as an amendment the following addition:

> Such adjourned meeting shall not initiate new business or change that which has been adopted.

Seconded.

Dr. Bert Ellis, California, moved that the amendment be referred back to the Business Committee. Carried.

The next amendment related to Section 3, Chapter 9, of the By-laws. At present it reads:

> In each Section a nominating committee of three members shall be elected by open ballot on the first day to make nominations for Section officers.

The Business Committee recommended that this amendment to the By-laws be sent to the Committee on Sections and Section Work for consideration and report.

On motion, the recommendation was adopted.

House of Delegates Meetings Defined.—Amendment to Section 3, Chapter 8, of the By-laws. The present section reads:

> The House of Delegates shall hold its first meeting of each annual session at 2 p. m. of the first day, and on subsequent days, at such time as may be necessary to complete its business, provided that it shall not meet at hours that will conflict with the general meetings of the Association.

The proposed amendment is:

> The House of Delegates shall meet at 10 o'clock on the day before that fixed as the first day of the annual session. It may adjourn from time to time as may be necessary to complete its business, provided, that it shall not meet at hours that conflict with the general meetings of the Association.

The Business Committee reported favorably on this amendment, and recommended its adoption.

On motion, the recommendation was adopted.

Limiting Number of Section Papers.—Amendment to Section 5, Chapter 9 of the By-laws:

> The number of papers on the program of any Section shall not exceed forty. No member shall read papers before more than two Sections at any session, and these papers must be on different subjects.

The Business Committee recommended the adoption of this amendment, and on motion the recommendation was concurred in.

Report of Committee on Legislation.

Dr. H. L. E. Johnson, Washington, D. C., presented the report of the *Committee on Legislation*, as follows:

The Committee on Legislation has the honor to make the following report for the year ending May, 1903: During the last session of the National Congress an antivivisection bill was introduced in the Senate, and your committee, acting promptly, secured sufficient support to impede effectually its official consideration and prevent its passage by that body. We respectfully ask the Association to approve our action on this measure, and disapprove the introduction of this or similar bills or measures in the future.

Under the present Constitution and By-laws your committee is regulated by the following:

> The committee on legislation shall report to the House of Delegates at each annual session its proceedings during the previous year, and recommend such action in respect to pending legislation as it shall deem proper. [See page 11, *Constitution and By-laws.*]

We regret very much the limitations placed on this committee by the above, and respectfully suggest legislation by the House of Delegates which will *give the Committee* on National Legislation more latitude and authority in dealing with medical legislation, both state and National.

Respectfully submitted, H. L. E. Johnson, Chairman.

On motion of Dr. McCormack, the report was referred to the Business Committee.

Report of Committee on Scientific Exhibit.

Dr. Frank B. Wynn, Indiana, presented the report of the Committee on Scientific Exhibit:

The chairman's address before the Section on Pathology and Physiology a year ago was devoted largely to a consideration of the future of the Pathologic Exhibit. It was recommended that the name be changed to Scientific Exhibit and that the work be placed in entire charge of a director, who should be selected by the Board of Trustees and paid reasonable compensation for his services. Your honorable body took favorable action on these recommendations, but suggested for good reason a postponement of the selection of a director for one year. The present Scientific Exhibit, therefore, was prepared under the old régime and has not been without embarrassments. With less than three months' time in which to accomplish the labor the committee has met the frequent excuse of lack of time; others have protested against taking material to so remote a point, insisting that territory contiguous to the place of meeting should provide the exhibit. Despite the remoteness of the meeting place from sources of pathologic supply, the loyal, saving remnant of the profession has come nobly to the rescue. It is a pleasure to place on this roster of honor the following names:

W. S. Thayer, Thomas S. Cullen, and Harry T. Marshall, Baltimore; E. R. LeCount, Winfield S. Hall, F. Robert Zeit, W. T. Eckley, James Nevins Hyde, F. H. Montgomery, L. E. Schmidt, and —— Harris, Chicago; Willard Bartlett, W. J. Calvert, St. Louis; O. L. Pothier, New Orleans; Frank B. Wynn and J. S. Wright, Indianapolis; H. J. Whitacre, John Miller and M. L. Heidingsfeld, Cincinnati; Calvin DeWitt, Washington; George Adami and M. E. Abbott, Montreal; E. B. Barnett, Havana; Jay F. Schamberg and Mihran K. Kassabian, Philadelphia; Robert Winthrop Gillman, Detroit; H. D. Vallin, St. Peter, Minn.; and W. S. Carter, Galveston.

It is not the province of this report to deal with the details of the Exhibit. Particulars will appear at a later date. It is sufficient to say that in point of excellence and efficiency the collection equals any previously given. Thirty odd exhibitors are participants. Especially to be thanked are those from distant points. In the list are to be noted those of national distinction as well as younger men fired with the true zeal, and laying the foundation for achievement in scientific medicine.

It has been found from experience that $500 is ample to cover the expense of the Scientific Exhibit if economically administered. It is recommended that this sum be appropriated annually.

All true physicians contribute more or less to the public weal in matters of hygiene and sanitary science. The ethical spirit prompts us to share without money and without price whatever knowledge we may gain in the healing of the sick. A small band is always to be found within our ranks, earnest, unselfish and untiring; willing to sacrifice time, labor and money in the furtherance of the higher ideals in medicine. Such make possible the Scientific Exhibit. To them are due not alone the praise of "well done," but the moral and material support of this body.

Following the natural and desirable tendency, the effort has been to condense and specialize the Exhibit with reference to location of the meeting places and topics to be prominently considered in the section work. With that end in view tropical diseases have received particular attention. Fine groups of specimens are shown, illuminating amebic and bacillary dysentery and excellent series of tuberculous and typhoid lesions for purposes of differentiation from the former. Excellent series are also shown illustrating malaria, yellow fever and plague. Related to surgery are very complete groups illustrative of surgical diseases of the kidney, bladder and prostate gland. Gynecologic effort has been directed toward the illumination of fibroid tumors and ectopic gestation. The realm of otology is represented by a fine series related to mastoid disease. The dermatologic group is directed chiefly to the illumination of the exanthemata. Besides these groups there are shown a large number of rare and beautiful miscellaneous specimens. Noteworthy exhibits are presented showing apparatus and the work of medical students as conducted under the most approved modern methods. The latter include physiologic experimentation and studies in clinical diagnosis, particularly with reference to the excreta.

It is deeply to be regretted that it has not been possible to arrange for the demonstration of the specimen groups before the respective sections, at stated hours, indicated on the published program. Most certainly this should be done in the future. In the preparation of the annual program, a competent director, in conjunction with the section officers as an advisory committee, will be able to correlate the work of the Exhibit with that of the sections. He will vary the character of the Exhibit from year to year, according to the place of meeting, tendencies in the medical world and to suit the topics of importance to come before the various sections. By this means the Scientific Exhibit will be made practically effective and the Association membership will come to realize that it is not, as many are prone to suppose, a mere adjunct of the Section on Pathology and Physiology, but belongs to the whole Association; that it is a valuable practical feature of the organization in which all reap profit. Further than mentioned it will fall to the director of the Exhibit to see that carefully prepared data are submitted with specimens and demonstrations. He should edit the same for publication and preservation in the archives of the Association. A small volume might be published each year containing a catalogue of the exhibits, clinical and descriptive data, plates, etc., which would become valuable for purposes of reference. Funds might with propriety be placed in his hands for the encouragement of research exhibits.

As stated on a previous occasion the Scientific Exhibit is in harmony with the spirit of the age which demands brevity; calls for facts rather than theories, and deeds rather than words. Contact of the man of pure science with him who applies scientific knowledge to practice, will tend to prevent narrowness and antagonisms on the one hand, and on the other prove conducive to harmony and mutual upbuilding. The mission of the physician is to minister to the suffering and heal the sick. Of this cardinal fact scientists should not lose sight. And on the part of clinicians there is need of appreciating more fully the great assistance afforded them by a practical knowledge of pathology and physiology. Whether a specimen be presented in the exhibit of the American Medical Association, in the state medical society or in a county medical society, the practical lesson taught is the same. Summed up it is that a practical knowledge of pathology constitutes the most substantial basis for skill in diagnosis. The physician reading a paper, reporting a case or presenting a specimen is, to be sure, rendering a service to his colleagues. He confers on himself a much greater benefit. The knowledge begotten in the labor becomes a joy and a blessing like his own child. This, and the consciousness of high purpose and duty well done, are the rewards of the scientific worker, which, in a measure, compensate for the meager financial return which is too often his lot.

Dr. Bishop, Pennsylvania, moved that the report be referred to the Business Committee; that this committee make its recommendation, then refer the report to the Board of Trustees and obtain a report of the board, so that the two reports can be made at one time, and thus save much time. Carried.

Report of Judicial Council.

Dr. N. S. Davis, Jr., Illinois, read the report of the Judicial Council, as follows:

The Judicial Council reports that letters were read from J. Austin Willis of Oakland, Cal., and from W. T. Salmon of Oklahoma City, and from doctors of San Diego, Cal., signed by J. C. Hearne and others. These letters asked for decisions on hypothetical cases. The council can only consider genuine cases properly referred to it; therefore, on motion, the council voted that the above letters of inquiry be referred back to the writers, and recommends that such matters should come through the county and state societies.

Philip Marvel, Chairman.

Report of Committee on Public Health.—The President called for the report of the Committee on Public Health.

Dr. H. A. West, Texas, a member of this committee, said that the duties of this committee were not well defined. In his correspondence with the chairman of the committee, his suggestion was, that matters concerning the public health should be referred to this committee, and that the committee was to serve merely in an advisory capacity as to the work to be referred to it.

Five Dentists Made Associate Members.—Dr. A. E. Baldwin, Illinois, in accordance with amendment to Section 5, Article 4, of the Constitution, in regard to associate members, recommended that the following be made associate members of the Section on Stomatology: C. V. Vignes, C. Edmund Kells, Paul de Verges, Jules J. Sarrazin, E. T. Belden.

On motion the Committee on Organization was authorized to codify the Constitution and By-laws and to correct any typographic errors contained therein.

Dr. M. L. Harris, Illinois, offered the following amendments:

Amendment to Chapter 12, Section 2, by eliminating the ection in its entirety.

Article 11 and Chapter 14 should each read:

> Three-fourths of the members present.

Article 9:

> The House of Delegates may recommend the appropriation of unds in accordance with, etc.

Moved to amend the Constitution and By-laws, so as to place the Association on the assessment plan, in accordance with the plan already adopted by many of the state societies.

The Sanders Resolutions on Public Health System.

Dr. W. H. Sanders offered resolutions, which were referred to the Business Committee:

> WHEREAS, The protection of the people from disease is the greatest aim of all true physicians; therefore, be it resolved by the American Medical Association,
>
> 1. That to formulate a complete, coherent, and constitutional public health system for this country be declared one of the most important achievements to which this body can devote itself.
>
> 2. That immediate steps be taken to construct such a system, and to submit it for adoption by the people of the states and of the nation.

To Have Standing Committee Reports Printed Before Session for Distribution.

Dr. Edwin Walker, Indiana, offered the following:

> *Resolved*, That all reports of standing committees shall be transmitted to the Secretary ten days before the annual session of the House of Delegates, and that all such reports shall be presented for distribution to the members of the House of Delegates.

This was referred to the Business Committee.

Association Petitions President Roosevelt to Appoint Medical Officer on Isthmian Canal Board.

Dr. W. H. Welch, Baltimore, introduced the following:

> Inasmuch as the construction of the Isthmian Canal is through a region in which, without energetic sanitary control there is sure to be enormous loss of human life from preventable diseases, particularly from pernicious malaria, and yellow fever, as well as great waste of energy and of money from disabilities caused by such diseases; and inasmuch as the measures for the restraint of these diseases, which have already achieved even their extermination in Cuba under American administration, require expert knowledge, based on practical familiarity with tropical diseases, experience in the application of these measures, and large authority in their administration, therefore,
>
> *Resolved*, That the American Medical Association begs most respectfully and earnestly to call to the attention of the President of the United States the importance of appointing as a member of the Isthmian Canal Commission a medical man possessed of the qualifications indicated. The Association is convinced that the mere employment of such a sanitary expert by the Commission will not be likely to secure the desired results.
>
> *Resolved*, That the Secretary of the Association transmit a copy of these resolutions to the President of the United States.

This was referred to the Business Committee.

On motion of Dr. Le Grande, Alabama, the Committee on Transportation and Place of Session was urged to have its report ready for presentation the first thing to-morrow morning.

Dr. Moyer, Illinois, said the Business Committee had neglected to recommend the adoption of the President's report. He moved that the report be adopted. Carried.

On motion of Dr. McCormack, Kentucky, secretaries of their respective state societies were invited to be present to discuss the subject of organization at the afternoon session and that, in the absence of the secretary, the president of the state society be invited to do so. Carried.

On motion the house then adjourned until 2 p. m.

WEDNESDAY, MAY 6—FIFTH MEETING.

The House of Delegates reconvened at 2:30 p. m., and was called to order by the President.

The Secretary called the roll, and there was a quorum present.

The Business Committee reported the order of business for the meeting, and on motion the report was accepted.

Pharmacists Again Considered.—Dr. Moyer, Illinois, speaking for the Business Committee, said that the committee had considered the amendment to Article 3, Section 7, of the By-laws, which was referred back to it, on pharmaceutic associate members, and begged leave to report as follows: The committee moves to amend, by striking out the words "graduates of recognized pharmaceutic schools and colleges" and inserting the word "reputable" before the word "pharmacists." The committee recommended this for adoption and, on motion of Dr. Hill, Wisconsin, the recommendation was concurred in. [See further modification below.]

Regarding the second amendment referred back to the Business Committee, which relates to Chapter 3, Section 10, of the By-laws, the committee recommended substituting the words "twenty-five of the voting members," so that the section, as amended, shall read:

> Twenty-five of the voting members composing the House of Delegates shall constitute a quorum for the transaction of business, provided, that at adjourned session, of any annual meeting, ten members shall constitute a quorum.

The committee also recommended the addition of these words:

> Such adjourned meeting shall not initiate new business or change that which has been adopted.

On motion of Dr. Wall, Buffalo, the recommendations of the committee were concurred in.

Dr. Moyer, speaking for the Business Commitee, said the report from the Section on Stomatology, in reference to associate members, required no action; that the adoption of the by-law, in reference to associate members, made them members in accordance with its provisions, if properly elected by the Section.

Isthmian Canal Resolutions Adopted.

The Business Committee reported favorably on the resolution offered by Dr. William H. Welch in reference to the sanitary construction of the Isthmian Canal, and recommended for adoption the resolution.

The recommendation was concurred in and, on motion of Dr McCormack, the resolution adopted.

In reference to the resolution offered by Dr. W. H. Sanders, Alabama, the committee recommended that it be referred to the Committee on Public Health, and on motion it was so ordered.

Printed Reports Adopted.

With reference to the resolution offered by Dr. Edwin Walker, Indiana, the Business Committee recommended that it be adopted; that the Secretary instruct the various committees to transmit their reports to him ten days before the annual session, that they may be printed.

On motion the recommendation was agreed to.

Legislation on Antivivisection Endorsed.

In reference to the first part of the report of the Committee on Legislation, which deals with the antivivisection bill, the Business Committee recommended it for adoption. The committee felt that this should be adopted, with the strongest possible endorsement by the House of Delegates.

On motion the recommendation of the Business Committee was adopted.

Dr. Moyer then offered the following resolution on behalf of the Business Committee:

> *Resolved*, That the American Medical Association approves the action of its committee in defeating the antivivisection bill recently pending before Congress, and that Congress be strongly urged to give no further consideration to legislation of that character in the future.

Seconded and carried.

Regarding the remaining portion of the report of the Committee on Legislation, which relates to the somewhat anomalous position in which the committee finds itself, the Business Committee recommended that this part of the report be referred back to the Committee on Organization and Codification of the Constitution and By-laws.

On motion the recommendation was adopted.

Dr. Wall, New York, introduced the following resolution:

> *Resolved*, It shall be a standing rule of the Association that no amendment or change in the Constitution and By-laws shall be acted on until it shall have been presented at a previous annual session.

This was referred to the Business Committee.

Report of Organization Committee—Forty-Four State Representatives Report.

Dr McCormack, Kentucky, chairman, read the report of the Committee on Organization.

At the conclusion of the report, representatives of forty-four states and territories made brief but very encouraging reports of the excellent work that is being done in reorganizing the medical profession throughout the country.

On motion the report of the Committee on Organization and the reports made by representatives of the respective states and territories were adopted, and a vote of thanks extended to the chairman, Dr. McCormack.

Money for Committee on Organization.

Dr. Charles A. L. Reed offered the following resolution, which was adopted:

Resolved, That with the concurrence of the Board of Trustees, $500, or so much thereof as may be necessary, shall be appropriated from the treasury, to pay the necessary expenses of the Committee on Organization.

On motion the House of Delegates then adjourned until 9 a. m., Thursday.

Thursday, May 7—Sixth Meeting.

The House of Delegates met at 9:20 a. m. and was called to order by the President.

The Secretary called the roll, and there was a quorum present.

The Secretary read the minutes of the two previous meetings, which, after some corrections had been made, were approved.

Dr. Moyer, Illinois, representing the Business Committee, reported on the order of procedure for the day, and on motion the report was adopted.

The Business Committee requested that the amendments to the By-Laws which were adopted relative to dental and pharmaceutic associate members be sent back to the committee for further consideration.

Dr. Moyer, Illinois, moved that the vote by which these amendments were adopted at a previous meeting be reconsidered. Carried.

Dr. Moyer, Illinois, then moved that the amendments be referred back to the Business Committee for further consideration. Carried.

Appropriation for Scientific Exhibit.

The Business Committee, to which was referred the matter of Scientific Exhibit, with instructions that the committee confer with the Board of Trustees relative to an appropriation necessary to continue the work of that committee, reported that the committee had had a conference and the trustees had advised that an appropriation not to exceed $500 be made and that, further, the Board of Trustees recommend the adoption of the committee's report.

It was moved and seconded that the recommendation of the Business Committee and of the Board of Trustees be adopted. Carried.

Amendments Must Lie Over One Year.

In reference to the standing resolution offered by Dr. Wall, Buffalo, at the last meeting, the committee begs to report favorably and to offer the following resolution:

Resolved, It shall be a standing rule of the Association that no amendment or change in the Constitution or By-Laws shall be acted on unless it shall have been presented at a previous annual session.

The committee moved its adoption. Seconded and carried.

Congress on Venereal Diseases at St. Louis Fair in 1904.

The Business Committee had considered carefully the question of the report of the Committee on Prophylaxis of Venereal Diseases and the proposal to hold a congress during the Louisiana Purchase Exposition and reported favorably on the report of the committee. Furthermore, the committee offered the following resolution:

1. The present Committee on Prophylaxis of Venereal Diseases to be continued and act as the central committee.

2. A co-operative committee be created, composed of one member for each state, to be appointed by the president of each state medical organization.

3. This central committee, with the approval of the co-operative committee, be authorized to organize and provide for a Congress for the Prophylaxis of Venereal Diseases during the existence of the Louisiana Purchase Exposition, to be held at St. Louis, with representatives of the Army, Navy and Public Health Service.

4. The central committee, with the approval of the co-operative committee, be directed to select officers to be presented to the proposed congress for action.

5. Each member of the co-operative committee is directed and expected to create an interest in his own state in the proposed congress.

6. The central committee is authorized to select from the officers of the Louisiana Purchase Exposition a suitable place for the meetings of the congress.

7. The legislative committee of the American Medical Association, in Washington, is directed to seek to secure an appropriation from the Congress of the United States of $5,000 for the expenses of the proposed congress.

8. A sum not to exceed $500 is recommended to be appropriated by the Board of Trustees of the American Medical Association for the expenses of the preparation of this congress, as proposed at the meeting of the House of Delegates Monday afternoon, May 4.

The Business Committee moved the adoption of the report of the committee, and on motion the report and resolution were adopted.

Dental and Pharmaceutic Members Provided For.

Dr. Moyer said the Business Committee was prepared to report in regard to the amendment to the By-Laws concerning dental members. He said they were described as "dental associate members." This was a mistake. They should be known simply as "dental and pharmaceutic members." The Association had associate members who should be kept distinct, and the word "associate" following the words "dental and pharmaceutic" was unnecessary The amended section reads:

Article 3, Section 6. Dental Members.—Dentists who hold the degree of D.D.S. from a reputable dental college and who are members of a recognized local or state dental society, may be admitted as dental members on recommendation of the officers of the Section on Stomatology and approval by a majority vote of the Section, the names of such members to be sent to the Secretary by the Secretary of the Section.

The Business Committee moved the adoption of this amendment. Carried.

Regarding Article 3, Section 7 of the By-Laws, the Business Committee recommended the following amendment, which was adopted:

Reputable pharmacists may be admitted as pharmaceutic members on recommendation of the officers of the Section on Materia Medica, Pharmacy and Therapeutics, subject to approval by a majority vote of the members of the Section, the names of such members to be sent to the Secretary by the Secretary of the Section.

Supplementary Report of the Board of Trustees.

Dr. T. J. Happel, president of the Board of Trustees, said: *I wish to make a supplementary* report of some of the work done by the Board of Trustees since the meeting of the Association in regard to matters that should be reported to the House of Delegates.

MONEY FOR SCIENTIFIC RESEARCH.

1. We have had presented to us several accounts. Five hundred dollars was asked for by the House of Delegates, to be appropriated for the use of the Committee on Scientific Research. The action of the Board of Trustees in regard to that matter is that the money has not yet been earned by the parties to whom the work has been assigned, but it will be paid when certified to properly by the chairman of the Committee on Scientific Research and presented to the chairman of the Board of Trustees.

SECTION SECRETARIES' EXPENSES ALLOWED.

2. Bills have been presented to the Board of Trustees, through the House of Delegates, from the secretaries of sections, ranging in amount from the sum of $4 up to a maximum of $15. These have been allowed and will be paid.

NATIONAL ORGANIZER CONTINUED.

3. The Board of Trustees would report that Dr. J. N. McCormack has been continued as organizer for the next twelve months on terms satisfactory to himself and the Board of Trustees.

UNVEILING RUSH MONUMENT.

4. In regard to the Rush monument, the board has been asked for an allowance of $500, or not to exceed that amount, to be used in defraying the expenses of unveiling the Rush monument. The board has willingly and gladly appropriated that sum which has been asked for, but not to exceed $500.

INDEFINITE APPROPRIATIONS BARRED.

5. The Board of Trustees wishes to emphasize a matter that is mentioned in its report which has been presented in printed form, namely, that no indefinite appropriation will be made by the Board of Trustees. In case a committee is appointed to do work and there is not a specific sum of money stated as an approximate amount to be expended by such committee, the board will not be authorized to meet any expenses connected with it. The board does not wish to be considered arbitrary in such matters, but, as custodians of the funds, the board wishes a limitation fixed by the House on any appropriation, and then it will be acted on.

COMMITTEE ON FOOD AND DRUGS BILL.

6. A bill was presented to the Board of Trustees by Cooley, Lewis & Elgas, attorneys, for legal opinion on account of the Committee on Food and Drugs on the question of the legality to elect trustees of the proposed corporation until such persons have been selected by the American Medical and the American Pharmaceutical Associations. The board can find no record of having appropriated money for securing legal opinion for this purpose, hence this account is disallowed.

SUPPLY OF THE NEW BUTTONS.

7. In regard to the matter of buttons, we believe the House of Delegates has already adopted the suggestion made by the Board of Trustees in regard to the button, and the board has directed me to report that a supply of buttons will be made in accordance with the suggestions of the board. These buttons can be procured at an approximate cost by all who do not possess them, and on the terms the Editor has been sending them out.

8. The account in connection with the Committee on Reorganization has been allowed.

9. The Board of Trustees has continued the appropriation of $500 for the use of the Committee on Scientific Exhibit as heretofore.

On motion of Dr. Charles A. L. Reed, Ohio, the supplementary report of the Board of Trustees was adopted.

Report of the Committee on Medical Ethics.

The next order was the report of the Enlarged Committee on Revised Code of Ethics.

Dr. E. Eliot Harris, New York, read the following report:

To the President and Members of the House of Delegates of the American Medical Association:

Your enlarged Committee on Medical Ethics, consisting of the special committee and one delegate from each state, have unanimously adopted the following report, entitled the "Principles of Medical Ethics of the American Medical Association," which is herewith submitted.

The following report of the Special Committee shall be printed as an explanatory preface to the Principles of Medical Ethics of the American Medical Association.

Gentlemen: Your committee has given extended and careful thought to the proposed revision of the Code of Medical Ethics referred to it for consideration. As you will note on reference to the caption of the report the word "code" has been eliminated and the expression "Principles of Medical Ethics of the American Medical Association" adopted as adequately descriptive. In reference to this change, it is proper to say that such action on its part is based on the idea that the American Medical Association may be conceived to occupy some such relation to the constituent state associations as the United States, through its Constitution, holds to the several states. The committee, for this reason, regards it as wiser to formulate the principles of medical ethics, without definite reference to "code" or penalties, thus leaving the respective states, to form such code, and establish such rules as they may regard to be fitting and proper, for regulating the professional conduct of their members, provided, of course, that in doing so there shall be no infringement on the established ethical principles of this Association. The committee regard as wise and well intended to facilitate the business of the parent organization and promote its harmony this course which leaves to the state association large discretionary powers concerning membership and other admittedly state affairs. Your committee has retained, to a large extent, the phraseology of the existing code, while aiming at condensation of expression and a better understanding of some of its statements. The report of the committee has been reached unanimously, without dissension or distrust on the part of its members, each aiming to formulate a result based on principle alone, and without regard to any past or present disagreements or misunderstandings whatsoever; such being the case, the committee invites your candid and unprejudiced attention to the results of its labor, feeling that at least some good has been accomplished.

Respectfully submitted,
E. Eliot Harris, Chairman.
William H. Welch.
T. J. Happel.
Joseph D. Bryant.

Principles of Medical Ethics.

The American Medical Association promulgates as a suggestive and advisory document the following:

Chapter I.—The Duties of Physicians to Their Patients.

Section 1.—Physicians should not only be ever ready to obey the calls of the sick and the injured, but should be mindful of the high character of their mission and of the responsibilities they must incur in the discharge of momentous duties. In their ministrations they should never forget that the comfort, the health and the lives of those entrusted to their care depend on skill, attention and fidelity. In deportment they should unite tenderness, cheerfulness and firmness, and thus inspire all sufferers with gratitude, respect and confidence. These observances are the more sacred because, generally, the only tribunal to adjudge penalties for unkindness, carelessness or neglect is their own conscience.

Sec. 2.—Every patient committed to the charge of a physician should be treated with attention and humanity, and reasonable indulgence should be granted to the caprices of the sick. Secrecy and delicacy should be strictly observed; and the familiar and confidential intercourse to which physicians are admitted, in their professional visits, should be guarded with the most scrupulous fidelity and honor.

Sec. 3.—The obligation of secrecy extends beyond the period of professional services; none of the privacies of individual or domestic life, no infirmity of disposition or flaw of character observed during medical attendance should ever be divulged by physicians, except when imperatively required by the laws of the state. The force of the obligation of secrecy is so great that physicians have been protected in its observance by courts of justice.

Sec. 4.—Frequent visits to the sick are often requisite, since they enable the physician to arrive at a more perfect knowledge of the disease, and to meet promptly every change which may occur. Unnecessary visits are to be avoided, as they give undue anxiety to the patient; but to secure the patient against irritating suspense and disappointment the regular and periodical visits of the physician should be made as nearly as possible at the hour when they may be reasonably expected by the patient.

Sec. 5.—Ordinarily, the physician should not be forward to make gloomy prognostications, but should not fail, on proper occasions, to give timely notice of dangerous manifestations to the friends of the patient; and even to the patient, if absolutely necessary. This notice, however, is at times so peculiarly alarming when given by the physician, that its deliverance may often be preferably assigned to another person of good judgment.

Sec. 6.—The physician should be a minister of hope and comfort to the sick, since life may be lengthened or shortened not only by the acts but by the words or manner of the physician, whose solemn duty is to avoid all utterances and actions having a tendency to discourage and depress the patient.

Sec. 7.—The medical attendant ought not to abandon a patient because deemed incurable; for, continued attention may be highly useful to the sufferer, and comforting to the relatives, even in the last period of the fatal malady, by alleviating pain and by soothing mental anguish.

Sec. 8.—The opportunity which a physician has of promoting and strengthening the good resolutions of patients suffering under the consequences of evil conduct ought never to be neglected. Good counsels, or even remonstrances, will give satisfaction, not offense, if they be tactfully proffered and evince a genuine love of virtue, accompanied by a sincere interest in the welfare of the person to whom they are addressed.

Chapter II.—The Duties of Physicians to Each Other and to the Profession at Large.

ARTICLE I.—DUTIES FOR THE SUPPORT OF PROFESSIONAL CHARACTER.

Section 1.—Everyone on entering the profession, and thereby becoming entitled to full professional fellowship, incurs an obligation to uphold its dignity and honor, to exalt its standing and to extend the bounds of its usefulness. It is inconsistent with the principles of medical science and it is incompatible with honorable standing in the profession for physicians to designate their practice as based on an exclusive dogma or a sectarian system of medicine.

Sec. 2.—The physician should observe strictly such laws as are instituted for the government of the members of the profession; should honor the fraternity as a body; should endeavor to promote the science and art of medicine and should entertain a due respect for those seniors who, by their labors, have contributed to its advancement.

Sec. 3.—Every physician should identify himself with the organized body of his profession as represented in the community in which he resides. The organization of local or county medical societies, where they do not exist, should be effected, so far as practicable. Such county societies, constituting as they do the chief element of strength in the organization of the profession, should have the active support of their members and should be made instruments for the cultivation of fellowship, for the exchange of professional experience, for the advancement of medical knowledge, for the maintenance of ethical standards, and for the promotion in general of the interests of the profession and the welfare of the public.

Sec. 4.—All county medical societies thus organized ought to place themselves in affiliation with their respective state associations, and these, in turn, with the American Medical Association.

Sec. 5.—There is no profession from the members of which greater purity of character and a higher standard of moral excellence are required than the medical; and to attain such eminence is a duty every physician owes alike to the profession and to patients. It is due to the patients, as without it their respect and confidence can not be commanded, and to the profession because no scientific attainments can compensate for the want of correct moral principles.

Sec. 6.—It is incumbent on physicians to be temperate in all things, for the practice of medicine requires the unremitting exercise of a clear and vigorous understanding; and in emergencies—for which no physician should be unprepared—a steady hand, an acute eye, and an unclouded mind are essential to the welfare and even to the life of a human being.

Sec. 7.—It is incompatible with honorable standing in the profession to resort to public advertisements or private cards inviting the attention of persons affected with particular diseases; to promise radical cures; to publish cases or operations in the daily prints, or to suffer such publications to be made; to invite laymen (other than relatives who may desire to be at hand) to be present at operations; to boast of cures and remedies; to adduce certificates of skill and success, or to employ any of the other methods of charlatans.

Sec. 8.—It is equally derogatory to professional character for physicians to hold patents for any surgical instruments or medicines; to accept rebates on prescriptions or surgical appliances; to assist unqualified persons to evade the legal restrictions governing the practice of medicine; or to dispense, or promote the use of, secret medicines, for if such nostrums are of real efficacy, any concealment regarding them is inconsistent with beneficence and professional liberality, and if mystery alone give them public notoriety, such craft implies either disgraceful ignorance or fraudulent avarice. It is highly reprehensible for physicians to give certificates attesting the efficacy of secret medicines, or other substances used therapeutically.

ARTICLE II.—PROFESSIONAL SERVICES OF PHYSICIANS TO EACH OTHER.

Section 1.—Physicians should not, as a general rule, undertake the treatment of themselves, nor of members of their family. In such circumstances they are peculiarly dependent on each other; therefore, kind offices and professional aid should always be cheerfully and gratuitously afforded. These visits ought not, however, to be obtrusively made, as they may give rise to embarrassment or interfere with that free choice on which such confidence depends.

Sec. 2.—All practicing physicians and their immediate family dependants are entitled to the gratuitous services of any one or more of the physicians residing near them.

Sec. 3.—When a physician is summoned from a distance to the bedside of a colleague in easy financial circumstances, a compensation, proportionate to traveling expenses and to the pecuniary loss entailed by absence from the accustomed field of professional labor, should be made by the patient or relatives.

Sec. 4.—When more than one physician is attending another, one of the number should take charge of the case, otherwise the concert of thought and action so essential to wise treatment can not be assured.

Sec. 5.—The affairs of life, the pursuit of health and the various accidents and contingencies to which a physician is peculiarly exposed sometimes require the temporary withdrawal of this physician from daily professional labor and the appointment of a colleague to act for a specified time. The colleague's compliance is an act of courtesy which should always be performed with the utmost consideration for the interest and character of the family physician.

ARTICLE III.—THE DUTIES OF PHYSICIANS IN REGARD TO CONSULTATIONS.

Section 1.—The broadest dictates of humanity should be obeyed by physicians whenever and wherever their services are needed to meet the emergencies of disease or accident.

Sec. 2.—Consultations should be promoted in difficult cases, as they contribute to confidence and more enlarged views of practice.

Sec. 3.—The utmost punctuality should be observed in the visits of physicians when they are to hold consultations, and this is generally practicable, for society has been so considerate as to allow the plea of a professional engagement to take precedence over all others.

Sec. 4.—As professional engagements may sometimes cause delay in attendance, the physician who first arrives should wait for a reasonable time, after which the consultation should be considered as postponed to a new appointment.

Sec. 5.—In consultations no insincerity, rivalry, or envy should be indulged; candor, probity and all due respect should be observed toward the physician in charge of the case.

Sec. 6.—No statement or discussion of the case should take place before the patient or friends, except in the presence of all the physicians attending, or by their common consent; and no opinions or prognostications should be delivered which are not the result of previous deliberation and concurrence.

Sec. 7.—No decision should restrain the attending physician from making such subsequent variations in the mode of treatment as any unexpected change in the character of the case may demand. But at the next consultation reasons for the variations should be stated. The same privilege, with its obligation, belongs to the consultant when sent for in an emergency during the absence of the family physician.

Sec. 8.—The attending physician, at any time, may prescribe for the patient; not so the consultant, when alone, except in a case of emergency or when called from a considerable distance. In the first instance the consultant should do what is needed, and in the second should do no more than make an examination of the patient and leave a written opinion, under seal, to be delivered to the attending physician.

Sec. 9.—All discussions in consultation should be held as confidential. Neither by words nor by manner should any of the participants in a consultation assert or intimate that any part of the treatment pursued did not receive his assent.

Sec. 10.—It may happen that two physicians can not agree in their views of the nature of a case and of the treatment to be pursued. In the event of such disagreement a third physician should, if practicable, be called in. None but the rarest and most exceptional circumstances would justify the consultant in taking charge of the case. He should not do so merely on the solicitation of the patient or friends.

Sec. 11.—A physician who is called in consultation should observe the most honorable and scrupulous regard for the character and standing of the attending physician, whose conduct of the case should be justified, as far as can be, consistently with a conscientious regard for truth, and no hint or insinuation should be thrown out which could impair the confidence reposed in the attending physician.

ARTICLE IV.—DUTIES OF PHYSICIANS IN CASES OF INTERFERENCE.

Section 1.—Medicine being a liberal profession, those admitted to its ranks should found their expectations of practice especially on the character and the extent of their medical education.

Sec. 2.—The physician, in his intercourse with a patient under the care of another physician, should observe the strictest caution and reserve; should give no disingenuous hints relative to the nature and treatment of the patient's disorder, nor should the course of conduct of the physician, directly or indirectly, tend to diminish the trust reposed in the attending physician.

Sec. 3.—The same circumspection should be observed when, from motives of business or friendship, a physician is prompted to visit a person who is under the direction of another physician. Indeed, such visits should be avoided, except under peculiar circumstances; and when they are made, no inquiries should be instituted relative to the nature of the disease, or the remedies employed, but the topics of conversation should be as foreign to the case as circumstances will admit.

Sec. 4.—A physician ought not to take charge of, or prescribe for, a patient who has recently been under the care of another physician, in the same illness, except in case of a sudden emergency, or in consultation with the physician previously in attendance, or when that physician has relinquished the case or has been dismissed in due form.

Sec. 5.—The physician acting in conformity with the preceding section should not make damaging insinuations regarding the practice previously adopted, and, indeed, should justify it if consistent with truth and probity; for it often happens that patients become dissatisfied when they are not immediately relieved, and, as many diseases are naturally protracted, the seeming want of success, in the first stage of treatment, affords no evidence of a lack of professional knowledge or skill.

Sec. 6.—When a physician is called to an urgent case, because the family attendant is not at hand, unless assistance in consultation is desired the former should resign the care of the patient immediately on the arrival of the family physician.

Sec. 7.—It often happens, in cases of sudden illness, and of accidents and injuries, owing to the alarm and anxiety of friends, that several physicians are simultaneously summoned. Under these circumstances, courtesy should assign the patient to the first who arrives and who, if necessary, may invoke the aid of some of those present. In such a case, however, the acting physician should request that the family physician be called, and should withdraw unless requested to continue in attendance.

Sec. 8.—Whenever a physician is called to the patient of another physician during the enforced absence of that physician the case should be relinquished on the return of the latter.

Sec. 9.—A physician, while visiting a sick person in the country, may be asked to see another physician's patient because of a sudden aggravation of the disease. On such an occasion the immediate needs of the patient should be attended to and the case relinquished on the arrival of the attending physician.

Sec. 10.—When a physician who has been engaged to attend an obstetric case is absent and another is sent for, delivery being accomplished during the vicarious attendance, the acting physician is entitled to the professional fee, but must resign the patient on the arrival of the physician first engaged.

ARTICLE V.—DIFFERENCES BETWEEN PHYSICIANS.

Section 1.—Diversity of opinion and opposition of interest may, in the medical as in other professions, sometimes occasion controversy and even contention. Whenever such unfortunate cases occur and can not be immediately adjusted, they should be referred to the arbitration of a sufficient number of impartial physicians.

Sec. 2.—A peculiar reserve must be maintained by physicians toward the public in regard to some professional questions, and as there exist many points in medical ethics and etiquette through which the feelings of physicians may be painfully assailed in their intercourse, and which can not be understood or appreciated by general society, neither the subject-matter of their differences nor the adjudication of the arbitrators should be made public.

ARTICLE VI.—COMPENSATION.

Section 1.—By the members of no profession are eleemosynary services more liberally dispensed than by the medical, but justice requires that some limits should be placed to their performance. Poverty, mutual professional obligations, and certain of the public duties named in Sections 1 and 2, of Chapter III, should always be recognized as presenting valid claims for gratuitous services; but neither institutions endowed by the public or by the rich, or by societies for mutual benefit, for life insurance, or for analogous purposes, nor any profession or occupation, can be admitted to possess such privilege.

Sec. 2.—It can not be justly expected of physicians to furnish certificates of inability to serve on juries, or to perform militia duty; to testify to the state of health of persons wishing to insure their lives, obtain pensions, or the like, without due compensation. But to persons in indigent circumstances such services should always be cheerfully and freely accorded.

Sec. 3.—Some general rules should be adopted by the physicians in every town or district relative to the minimum pecuniary acknowledgment from their patients; and it should be deemed a point of honor to adhere to these rules with as much uniformity as varying circumstances will admit.

SEC. 4.—It is derogatory to professional character for physicians to pay or offer to pay commissions to any person whatsoever who may recommend to them patients requiring general or special treatment or surgical operations. It is equally derogatory to professional character for physicians to solicit or to receive such commissions.

CHAPTER III.—THE DUTIES OF THE PROFESSION TO THE PUBLIC.

SECTION 1.—As good citizens it is the duty of physicians to be very vigilant for the welfare of the community, and to bear their part in sustaining its laws, institutions and burdens; especially should they be ready to co-operate with the proper authorities in the administration and the observance of sanitary laws and regulations, and they should also be ever ready to give counsel to the public in relation to subjects especially appertaining to their profession, as on questions of sanitary police, public hygiene and legal medicine.

SEC. 2.—It is the province of physicians to enlighten the public in regard to quarantine regulations; to the location, arrangement, and dietaries of hospitals, asylums, schools, prisons and similar institutions; in regard to measures for the prevention of epidemic and contagious diseases; and when pestilence prevails, it is their duty to face the danger, and to continue their labors for the alleviation of the suffering people, even at the risk of their own lives.

SEC. 3.—Physicians, when called on by legally constituted authorities, should always be ready to enlighten inquests and courts of justice on subjects strictly medical, such as involve questions relating to sanity, legitimacy, murder by poison or other violent means, and various other subjects embraced in the science of medical jurisprudence. It is but just, however, for them to expect due compensation for their services.

SEC. 4.—It is the duty of physicians, who are frequent witnesses of the great wrongs committed by charlatans, and of the injury to health and even destruction of life caused by the use of their treatment, to enlighten the public on these subjects, and to make known the injuries sustained by the unwary from the devices and pretensions of artful impostors.

SEC. 5.—It is the duty of physicians to recognize and by legitimate patronage to promote the profession of pharmacy, on the skill and proficiency of which depends the reliability of remedies, but any pharmacist who, although educated in his own profession, is not a qualified physician, and who assumes to prescribe for the sick, ought not to receive such countenance and support. Any druggist or pharmacist who dispenses deteriorated or sophisticated drugs or who substitutes one remedy for another designated in a prescription, ought thereby to forfeit the recognition and influence of physicians.

Principles of Ethics Adopted.

Dr. E. Eliot Harris, New York—In view of the fact that the report I have just read was unanimously adopted by the enlarged committee, consisting of the special committee, and one delegate from each state, I move the adoption by this house of the report as read.

Dr. Charles A. L. Reed, Ohio, in rising to second the motion, said that he wished to testify to the absolute harmony which has prevailed in this conference, and to congratulate the Association on the fact that by the adoption of this report we put an end to a controversial question which has disturbed our councils for many years. (Applause.)

The President put the motion, and it was adopted unanimously, amid tumultuous and prolonged applause.

Dr. E. Eliot Harris, New York, then offered the following resolution, and moved its adoption:

Resolved, That the Special Committee [illegible] Principles of Medical Ethics of the Americ[illegible] and that it be signed by the President and Secretary of this Association.

Seconded and unanimously carried.

Report of Committee on Transportation and Place of Annual Session.

Dr. Ellis, California, reported on behalf of the Committee on Transportation and Place of Session.

Invitations were received by the committee from Milwaukee, Cincinnati, St. Louis, and Atlantic City, and it was suggested to the committee by the President that the Association meet in Washington. In regard to Cincinnati and St. Louis, the invitations did not come from the medical profession. In regard to Washington, the committee telegraphed for rates in regard to hotels, and as the replies to telegrams were not satisfactory, Washington was eliminated as a place of session. The committee recommended unanimously Atlantic City, N. J., as the place of the next session.

It was moved and seconded that the recommendation be adopted.

Dr. Sarles, Wisconsin, moved to amend the report of the committee by substituting Milwaukee for Atlantic City. Seconded.

After some discussion, which was participated in by Drs. Moyer, Dorsett, Dean and Hill, the President put the substitute, and it was declared lost.

Atlantic City Session in 1904.—The house then voted on the original motion, and it was adopted.

The Secretary read a resolution from the Section on Hygiene and Sanitary Science, which, on motion, was referred to the Business Committee.

District Branches of the Association.

Dr. Edwin Walker, Indiana, president of the Mississippi Valley Medical Association, said that at the last meeting of this association a resolution was unanimously passed, declaring that it was desirable that it should become a distinct branch of the American Medical Association. He asked, therefore, that this matter be referred to the Committee on Organization.

Dr. McCormack, Kentucky, moved that the matter be referred to the Committee on Organization, and that authority be granted that committee to consider the question of the division of this country into branch associations, in accordance with the plan laid down in the By-laws, and that the committee be instructed to report on such a plan at the next annual session of the Association. Seconded and carried.

Report on National Bureau of Medicines and Foods.

Dr. Ellis, California, presented the report of the Provisional Committee on the Establishment of a National Bureau of Medicines and Foods.

Your committee has very carefully investigated the matter submitted to it both in general plan and as to the scientific, business and legal details, and while the matter will demand of the joint committees an enormous amount of work, there is nothing in the plan that can not be accomplished if the two associations co-operate with and support their committees. The matter has reached a point where a little more time devoted to energetically prosecuting the work will see a successful accomplishment of the objects desired, whereas a postponement of all further work for a year would result in the indefinite continuance of the conditions which have existed and which have been deplored since 1881.

The bureau plan has in contemplation the idea of establishing a board of qualified experts who should represent the interests and the support of the professions of medicine and pharmacy, and through the medium of such a board secure (1) more general conformity to the standards of the pharmacopeia; (2) drugs and chemicals and foodstuffs that will be actually as labeled and can be relied on; and (3) deal in a proper professional and ethical manner with the large and ever-increasing number of proprietary mixtures and preparations that are being presented to the medical profession. This was first suggested by Dr. F. E. Stewart at the session of the American Medical Association in 1881.

This idea has been elaborated and plans have been formulated which it is thought will secure the objects desired. (The detailed plans will be submitted if so desired, but they are necessarily extensive and complex, and several hours would be required to fully consider them.) These plans have been approved by a number of representative physicians and pharmacists, and it is evident that of the professional interests and the people of this country (and especially the members of the American Medical and the American Pharmaceutical Associations) really desire relief from the present unfortunate and distressing condition of materia medica and pharmacy, and of adulterated and dishonest foodstuffs, such relief is at hand.

Primarily, this plan contemplates the voluntary association of honest manufacturers and pharmacists who will agree with the board of experts representing medicine and pharmacy on standards of identity, purity, quality and strength to which their products shall comply, and will further agree to carry out these standards and to comply with the necessary rules governing manufacture, etc.

Organization for the purposes indicated would be begun by the formation of a corporation on the membership plan—no stock issued and not for profit—under the name of the "National Bureau of Medicines and Foods," and all members of the American Medical and the American Pharmaceutical Associations would be members of this bureau. It is proposed that the board of directors governing this bureau be elected by these two associations, each having five directors, one from each association retiring annually and a successor elected for five years.

In order to indicate to the physician, the pharmacist or the purchaser such articles as comply with the standards of identity, purity, quality and strength, and may in consequence be

Addition to Hospital.—A large addition is to be made to the large post hospital at Fort Meade. Plans have been received and it is expected that the contract for the erection of the new building will soon be awarded.

State Board of Medical Examiners.—Under the new law the Governor has made the following appointments to the State Board of Medical Examiners: Regulars—Drs. Stephen Olney, Sioux Falls; John W. Freeman, Lead; John L. Foxton, Huron, and H. E. McNutt, Aberdeen. Homeopaths—Drs. Alonzo A. Cotton, Vermillion, and Hans M. Finnerud, Watertown. Eclectic—Dr. Harry S. Graves, Hurley. The board organized by the election of Dr. Stephen Olney, president; Dr. Harry S. Graves, vice-president, and Dr. H. E. McNutt, secretary and treasurer. The first examination will be held in Sioux Falls, July 8.

GENERAL.

Cholera has reappeared at Manila and in the archipelago and is increasing with the return of the hot season.

The Association of American Medical Colleges met, under the presidency of Dr. William L. Rodman, at New Orleans, May 4 and 5. The principal business was the consideration of the report of the Committee on By-laws, which advocated and recommended the raising of entrance requirements. The report was adopted with a few amendments, to go into effect July 1, 1905. The officers for next year are: President, J. R. Guthrie, Dubuque, Iowa; first vice-president, George M. Kober, Washington, D. C.; second vice-president, J. Oliver, Cincinnati; secretary-treasurer, Fred C. Zapffe, Chicago; judicial council, W. J. Means, Columbus, Ohio; J. M. Dodson, Chicago; T. J. Hawkins, Denver; H. B. Ward, Lincoln, Neb.; Randolph Winslow, Baltimore; J. D. Griffith, Kansas City, Mo., and J. W. Holland, Philadelphia.

FOREIGN.

Homage to Huchard.—The friends and pupils of Prof. H. Huchard of Paris are collecting subscriptions to present him with a bronze plaque on the occasion of his promotion to be officer in the Legion d'Honneur.

Hygienic School Hours.—In Galicia the grammar schools have a single session, from 8 till 1, and the desirability of a change has been discussed. The medical association advised in favor of the present hours, as an afternoon session interferes with digestion and assimilation, while the best mental work is done in the morning. Owing to the prevailing local social, economic and climatic conditions the association believed that two sessions would entail many more disadvantages than the present plan.

Romiti's Silver Jubilee.—Prof. G. Romiti of Pisa celebrated, March 5, the twenty-fifth year of his incumbency of the chair of anatomy at Siena and Pisa. He was presented with a souvenir volume of the "Archivio Italiano di Anatomia ed Embriologia," a gold medal and several scientists gave him special volumes of their works. The chairs of anatomy at five other Italian universities are now occupied by his pupils and two others by pupils of those who have studied with him. His manual of anatomy is the text-book in use in Italy, and he has published more than a hundred monographs on anatomy and embryology.

Campaign Against Charlatans in Germany.—One of the deputies in the Wurtemberg legislature recently urged that the government should assist physicians in their campaign against charlatans more than heretofore. He also stated that the struggle in which the physicians are now engaged against the starvation fees given by the sick benefit societies is a laudable effort to counteract the degradation and proletarianizing of the medical profession. The minister of the interior replied that the matter was one for the general government to decide, not the states for themselves, but that the imperial Reichstag would find that the Wurtemberg assembly would be glad to co-operate with the general government in the matter.

The National Asylum for Insanity of Rio de Janeiro.—Dr. Julians Moreira, professor of psychiatry and neurology in the Medical School of Bahia and co-editor of the "Gaseta Medica" of Bahia, has been appointed director of this great asylum. The institution is to be enlarged shortly by the addition of new buildings, the ground for which, adjoining the present property, has already been purchased. The erection of these new buildings will increase the capacity of the hospital to 1,000 beds instead of the present 900 beds. Funds for the erection of the buildings are available, which will be sufficient to provide for a modern equipment of the new wards. Plans for the new epileptic ward are being prepared. It will be detached from the other buildings.

The Contract Practice Troubles in Germany.—The agitation in regard to the pending legislation to increase the length of medical attendance for members of sick benefit societies, the "Muenchener Med. Wochft." declares, is by no means confined to South Germany, as quoted in our last number. It is able to cite proceedings of various medical organizations, etc, which show that the movement is nearly general. The necessity of energetic measures to compel the societies to increase the remuneration for the double task to be imposed is rousing physicians to mold public opinion through the daily papers. A number of lay papers have recently contained articles, evidently written by physicians and having a marked effect in enlightening the public. Among the best is an article by Dr. F. Haker of Munich, published in No. 90 of the "Allg. Ztg.," entitled "The Position of German Physicians and Their Struggle Against the Decline of the Profession," and mentioned as a model of captivating and dignified style. The arbitration at Mülhausen was fruitless, and the physicians have resumed their former attitude, refusing to serve further as contract physicians and not only demanding the ordinary rates for medical attendance, but refusing credit. Consequently, the officers of the societies have to be accessible to the members at any hour, day or night.

Physicians' Insurance Association at Vienna.—The Vienna "Medical Doktoren-Collegium" now has a membership of 715 physicians, with a capital of about $1,700,000. One of the features is the "widows' and orphans' society," with 404 members. It paid pensions to 187 widows and 3 groups of orphans, about $50,000 in all, last year. The "support institute" had 238 members and its fund amounted to $85,000. It supplied permanent support to 6 members and temporary to 10, expending $2,000 in this way. The "pension institute" had 238 members and a fund of $280,000. It pays out $240 annually to 36 pensioners, and paid to the heirs of deceased physicians about $1,520 during the year. There is also a "health resort fund" to enable members of the collegium to have the benefit of a course of mineral waters or trip elsewhere. There are also endowments for needy physicians, 35 representing $40 to $176 a year; 12 for widows and orphans of physicians, and 16 for the sons of physicians, representing $8.50 to $236 a year and free places in the institutes. The collegium sent out 80,000 circulars last year to physicians throughout Austria, endeavoring to secure new adherents, but only 80 responded and, as 41 died or resigned, the gain was merely 39. A letter from Vienna to the "Munich Med. Wochft." comments that this apathy in regard to such an important organization, with dues 15 per cent. less than lay insurance societies, can be attributed only to indolence on the part of the majority of the profession, or else that the majority are in such financial straits that even the modest dues required are beyond their reach—probably both causes co-operate, the writer concludes. Switzerland has two similar medical insurance societies, the combined capital about $38,000. One is 3 and the other 20 years old.

Book Notices.

The Surgery of the Head. By Bayard Holmes, B.S., M.D., Professor of Surgery in the University of Illinois. Cloth. Pp. 569. Price, $2.50. New York: D. Appleton & Co. 1903.

The mass of surgical facts regarding bacteriology and histology accumulated within the present era is awe-inspiring. Only specialists can hope to master a tithe of them; and individuals can scarcely expect to write systematic and comprehensive text-books of surgery. Indeed, attempts to include facts and principles in treatises by a single author have almost been abandoned, while composite works of great bulk, in which each chapter is assigned to an individual writer, have long been the order of the day. Of late even an encyclopedia of surgery has been in course of preparation and issue under the editorship of the distinguished Kocher. Thus facts are given the maximum prominence, while the principles, the informing and unifying pathologic spirit of surgery are likely, at least in this instance, to suffer total eclipse.

Billroth's classical "Principles of Surgery" has run through nearly twenty German editions, has been printed in many languages, and is profitable classical reading to-day. This is true because Billroth recognized the permanent and immutable as well as the temporary verities of surgery.

Holmes'. book is founded on an accurate knowledge of the modern principles of pedagogics. He realizes that the student who learns a general principle of surgical pathology or practice is, by the very acquisition, a changed man. If many principles are learned, the theory of surgery is in the grasp of the student. Holmes' book is written in a new old way and represents a return to the simpler style of a simpler surgery. Actual clinical cases are used as a starting point in treating principles, and in the choice of these cases the writer has not depended on his own experience alone but has freely quoted from current literature. The charm of Sir Astley Cooper, of Trousseau and of Billroth is in these simple pages. He who is in search of catalogued facts will consult an encyclopedia, a book of logarithms or interest tables, as need may indicate. But every seeker for the subtle relation between fact and theory which, when acquired, makes the real surgeon rather than the mere technician will read this new work. Practitioner and student may thus find equal profit in its pages. We predict that not only will this work find many readers but also many imitators, and that to the lasting profit of our genial art.

The Evolution of Man and His Mind. A History and Discussion of the Evolution and Relation of the Mind and Body of Man and Animals. By S. V. Clevenger, M.D., Author of Medical Jurisprudence of Insanity. Cloth. Pp. 615. Price, $5.00. Chicago: Evolution Publishing Co. 1903.

This is a comprehensive work, covering the history, ethnology, biology and sociology of humanity in a compass of a little over 600 pages. The author is evidently a man of wide reading and a naturally suggestive and ingenious thinker. Notwithstanding his generally scientific accuracy, we notice several places wherein one might think that his information has been erroneous. At least, in some instances, he appears to have accepted as facts statements that draw on the credulity of the reader and seem to us somewhat irrational. Among these statements we can include such a one as that of the osteopathic school in Missouri selecting its anatomic subjects "on the hoof" in one of the asylums and some few other like instances, indicating a lack of faith in modern popular and political administration, which we think is undeserved. There is also a strong element of the author's personality evident in many of the pages in his comments on current matters, politics and the questions that come up from time to time in the newspapers. Perhaps the best chapters are those on heredity, hunger and love, the development of the mind, the senses and feelings and the instincts and emotions. The chapter on superstition will not suit the average believer in the Christian or in any other special religion, for the author is evidently, in his beliefs, what is sometimes called "broad" and his remarks on the subject are rather heterodox. His views on sociology also have several points for criticism, though, in the main, there is much of which everyone must approve. We regret that the author did not take time to get up an index, for a book of this character without an index is very unsatisfactory. It is not a book that one will pick up and read through as one would read a novel—at least the average individual will not do this—but there are subjects covered that one would be glad to look up in an index without having to wade through several chapters to find what is wanted.

The Mycology of the Mouth. A Text-Book of Oral Bacteria. By Kenneth Weldon Goadby, D.P.H. Camb., L.R.C.P., M.R.C.S., L.D.S. Eng., Bacteriologist and Lecturer on Bacteriology, National Dental Hospital. With Illustrations. Cloth. Pp. 241. Price. $3.00 net. London, New York, Bombay: Longmans, Green & Co. 1903.

The reason for use of the term "mycology," says the author, is that the micro-organisms of the mouth include species belonging to the higher orders than the bacteria or schzomycetes. The duplication of terms seems wholly unjustifiable since bacteria are bacteria wherever they may be found. While this work of some 240 pages is not strictly original, the author has brought together all that is known up to the present time on the bacteria of the mouth. The work is conveniently divided into thirteen chapters with an appendix. Much of the early work of Miller and Leon Williams is recognized, while the author has added considerable from his own research.

The micro-photographic illustrations are excellently done. While many believe in schematic illustrations for the student, experience has proven that micro-photographs give a better idea of what is found when the student is searching for a given object. There is no reference to many American authors, although considerable work has been done along this line in this country.

Muco-Membranous Entero-Colitis. Symptoms, Complications, Etiology and Treatment. By Maurice De Langenhagen, M.D., Consulting Physician at Polombieres, Vosges, France. Cloth. Pp. 115. Price, $1.25. London: J. & A. Churchill. Philadelphia: P. Blakiston's Son & Co. 1903.

This little work is written by a local specialist who has taken up a comparatively limited subject, but one which, because of its frequency and associations, is certainly worthy of a monograph. Muco-membranous colitis is one of the commonest accompaniments or, perhaps, causes of neurasthenic conditions, and a better knowledge of its symptoms and management is certainly desirable. The author points out its frequency in Europe, and we believe it is hardly likely to be found less frequent in this country, though, unfortunately, it has not received the attention that it deserves. While not a fatal disorder, it is sometimes an exceedingly obstinate and refractory one and anything that will enlighten us as to its treatment is of advantage. The volume is likely to be of service, therefore, to the general practitioner.

A Text-Book of Pharmacology and Therapeutics, or the Action of Drugs in Health and Disease. By Arthur R. Cushny, M.A., M.D. Aberd., Professor of Materia Medica and Therapeutics in the University of Michigan. Third Edition, Revised and Enlarged. Illustrated with 52 Engravings. Cloth. Pp. 756. Price, $3.75. Philadelphia and New York: Lea Brothers & Co.

The appearance of the third edition of Cushny's pharmacology and therapeutics, only eighteen months after the preceding one, shows the favor with which the book has been received. The present edition contains certain additions, such as fuller remarks on spinal anesthesia, suprarenal extracts, etc. The author has also appended to this edition a classification of drugs according to their therapeutic uses, which he has found useful in his teaching of pharmacology.

State Boards of Registration.

Maine Report.—Dr. A. K. P. Meserve, Portland, secretary of the Maine Board of Registration of Medicine, reports the examination held at Augusta, March 24, 1903, as follows: Number of subjects examined in, 12; total questions, 80; percentage required to pass, 75 average and not less than 60 in any one branch; examination was partly oral and partly written; total number examined, 7; all of whom passed.

PASSED.

Medical Organization.

Outagamie County (Wis.) Medical Society.

The physicians of Outagamie County have organized a medical society to be affiliated with the Wisconsin State Medical Society and the American Medical Association.

Seward County (Neb.) Medical Society.

The physicians of Seward County met at Seward, April 24, and organized a county society, with the following officers: Dr. Charles W. Doty, Beaver Crossing, president; Dr. Jefferson T. Potter, Seward, vice-president, and Dr. Charles O. Petty, Beaver Crossing, secretary.

McDowell Medical Society.

Physicians of Franklin, Gasconade, Osage and Maries counties, Mo., met at Owensville, April 4, and organized a district medical society, with the following officers: Dr. John D. Seba, Bland, president; Dr. James E. Jose, Koenig, vice-president; Dr. A. C. Wood, Owensville, secretary, and Dr. Julius W. Nieweg, Owensville, treasurer.

Tompkins County (N. Y.) Medical Association.

The members of the Third District Branch residing in Tompkins County met, April 14, and organized this association. The following officers were elected: President, Dr. John S. Kirkendall, Ithaca; vice-president, Dr. William C. Douglass, Ithaca; secretary and treasurer, Dr. Marcus A. Dumond, Ithaca. Dr. Chauncey P. Biggs was elected fellow and Dr. E. R. Osterhout, alternate.

Otero County (Colo.) Medical Society.

This society met in January and reorganized under the new constitution and by-laws as recommended by the American Medical Association. The following officers were elected for the ensuing year: Dr. B. F. Haskins, La Junta, president; Dr. E. W. Kearby, Rocky Ford, vice-president; Dr. Arthur R. Timerman, La Junta, secretary; Dr. James F. Kearns, La Junta, treasurer, and Dr. Frank Finney, La Junta, member of the house of delegates.

Societies.

COMING MEETINGS.

Association of Military Surgeons of the United States, Boston, May 19-21.
New Hampshire Medical Society, Concord, May 21-22.
North Dakota State Medical Society, Bismarck, May 21-22.
South Dakota State Medical Society, Mitchell, May 27-28.
Connecticut Medical Society, Hartford, May 27-28.
West Virginia State Medical Association, Charleston, May 26-28.
Indian Territory Medical Association, South McAlester, June 2-3.
Medical Society of the State of North Carolina, Hot Springs, June 2.
Ohio State Medical Society, Dayton, June 3-5.
Rhode Island Medical Society, Providence, June 4.
Wisconsin State Medical Society, Milwaukee, June 3-5.
Maine Medical Association, Portland, June 3-5.
Indiana State Medical Society, Richmond, June 4-5.
Medical Society of Delaware, Dover, June 9.
Massachusetts Medical Society, Boston, June 9-10.
Michigan State Medical Society, Detroit, June 11-12.
Minnesota State Medical Society, St. Paul, June 17.
Medical Association of Montana, Helena, June 17-18.
Medical Society of New Jersey, Asbury Park, June 23-25.

Medical Society of Nova Scotia.—The thirty-fifth annual meeting will be held in Antigonish, July 1 and 2.

Maritime Medical Association.—The thirteenth annual meeting will be held in St. John, N. B., July 22 and 23.

American Electro-Therapeutic Association.—The thirteenth annual meeting will be held at Atlantic City, N. J., September 22, 23 and 24, under the presidency of Dr. Daniel R. Brower, Chicago.

Buffalo Academy of Medicine.—The nomination of officers resulted as follows: President, Dr. Joseph W. Grosvenor; secretary, Dr. Edwin A. Bowerman; treasurer, Dr. Charles S. Jewett, and trustee, Dr. Ludwig Schroeter.

Eastern Dakota Medical Association.—The annual meeting was held at Brookings, S. D., April 14. Dr. Albert J. Cox, Tyler, Minn., was elected president; Dr. Edwin Klaveness, Brookings, vice-president, and Dr. Joseph G. Parsons, Brookings, secretary and treasurer.

La Salle County (Ill.) Medical Society.—The fiftieth annual meeting was held in Ottawa, April 21. Dr. William S. Sterrett, Marseilles, was elected president; Dr. Fred A. Guthrie, La Salle, vice-president; and Dr. William A. Pike, Ottawa, secretary. Next year's meeting will be held in Streator.

Seneca County (N. Y.) Medical Association.—At the annual meeting held in Seneca Falls, April 16, the following officers were elected: President, Dr. William A. Macy, Willard; vice-president, Dr. George A. Bellows, Waterloo; secretary, Dr. J. Spencer Purdy, Seneca Falls, and treasurer, Dr. Carroll B. Bacon, Waterloo.

De Witt County (Ill.) Medical Society.—At the annual meeting Dr. Joseph C. Myers, Clinton, was elected president; Dr. Samuel L. Thorpe, Kenney, vice-president; Dr. John H. Tyler, Clinton, secretary and treasurer; Dr. Albert E. Campbell, Clinton, delegate to the Illinois State Medical Society, and Dr. Guy G. Dowdall, Clinton, alternate.

Hunterdon County (N. J.) Medical Society.—The annual meeting was held at Flemington, April 28. Dr. William H. Schenck, Flemington, was elected president; Dr. Leon T. Salmon, Lambertville, first vice-president; Dr. Peter C. Young, Ringoes, second vice-president; Dr. Obadiah H. Sprowl, Flemington, secretary; Dr. Isaac S. Cramer, Flemington, treasurer.

District Medical Society of Central Illinois.—At the twenty-ninth annual meeting held in Pana, April 21, the following officers were elected: President, Dr. John H. Miller, Pana; vice-presidents, Drs. Thomas E. Cherry, Cowden, and William J. Eddy, Shelbyville; treasurer, Dr. John N. Nelms, Taylorville, and secretary, Dr. Frederick J. Eberspacher, Pana. The next meeting will also be held in Pana.

American Laryngological, Rhinological and Otological Society.—The ninth annual meeting was held at Lexington, Ky., April 23, 24 and 25, under the presidency of Dr. Joseph A. Stucky. The following officers were elected: President, Dr. Norval H. Pierce, Chicago; vice-presidents, Drs. George L. Richards, Fall River, Mass., Chevalier Jackson, Pittsburg, Redmond W. Payne, San Francisco, and John F. Woodward, Norfolk, Va.; secretary, Dr. Wendell C. Phillips, New York, and treasurer, Dr. Ewing W. Day, Pittsburg.

Alumnae Association, Woman's Medical College.—The alumnæ met for the twenty-third annual meeting at Chicago, April 29, about 60 being in attendance. The following officers were elected: President, Dr. Sarah Hackett Stevenson, Chicago; vice-presidents, Drs. Mary E. Bates, Denver, and Anna Ross Lapham, Chicago; secretary, Dr. Eliza H. Root, Chicago; treasurer, Dr. Mary C. Hollister, Chicago, and executive committee, Drs. Anna E. Blount, Oak Park, Ill., Rose Millard, Chicago, and Minnie K. Bowles, Joliet, Ill.

Association of Railway Surgeons of the Pacific Slope.—At the annual meeting held recently in Santa Barbara, Cal., resolutions were passed expressing regret at the death of Dr. Matthew Gardner. The following officers were elected, after which the association adjourned out of respect to the memory of Dr. Gardner: Dr. Walter B. Coffey, San Francisco, president; Drs. Norman H. Morrison, Los Angeles, Charles N. Ellinwood, San Francisco, and Kenneth A. J. Mackenzie, Portland, Ore., vice-presidents; Dr. James P. Dunn, Oakland, secretary, and Dr. Frank K. Ainsworth, Los Angeles, treasurer.

Massachusetts Association of Boards of Health.—At the meeting in Boston, April 30, Mrs. Ellen M. Richards spoke on "Educational Sanitary Inspection," and Mrs. von Wagner told of the way in which the poor of Yonkers, N. Y., are taught to abate nuisances and live decently. Dr. Frank L. Morse of the State Board of Health spoke on "The Recent Smallpox Epidemic in Massachusetts, giving a powerful statistical and practical plea for universal and repeated vaccination. Last year the disease was more prevalent than at any time since the epidemic of 1872. During the year there were 2,300 cases, with 278 deaths in the state. Out of this number of deaths 200 were of persons who had not been vaccinated. The association took action favoring the state production of antitoxin and vaccine.

LOUISIANA STATE MEDICAL SOCIETY.

Twenty-fourth Annual Meeting, held in New Orleans, April 28 to 30, 1903.

The President, Dr. Isadore Dyer, in the Chair.

Opening Sessions.

The morning session was largely devoted to organization. The address of welcome was delivered by Hon. Arthur McGuirk. The report of the Committee on Arrangements was presented by Dr. Louis G. LeBeuf.

The president, Dr. Isadore Dyer, New Orleans, in his preliminary remarks, noted the fact of the paucity of local societies and that the profession in Louisiana is just awakening to the fact that it is only by a spirit of fraternity among the units that broader community interests can be created. He commended and advised the adoption of the constitution as suggested by the American Medical Association for state societies, and believed that it must ultimately obtain in every state where cohesion of medical men is desired.

Salt as a Stimulant.

Dr. S. L. Williams, Oak Ridge, read a paper in which he considered the use of normal salt solutions in the treatment of septic and toxic conditions. His experience for the past three years has demonstrated the efficiency of salt solution and butter administered subcutaneously and percutaneously in enteric fever and scarlet fever. In case of habitual alcoholics the treatment was not efficient.

Malarial Hemoglobinuria.

Dr. Ladis Lazaro, Washington, presented a paper on this subject, which brought out active discussion, bearing chiefly on the use or non-use of quinin in malarial diseases; the advocates and opponents of quinin fighting, without coming to any conclusion, the battle which has been fought for years and always without decisive results.

Anesthesia.

Dr. T. Edgar Schumpert, Shreveport, read a report on chloroform anesthesia at the morning session of the second day, detailing methods to be followed in the administration of the anesthetic by which danger can be avoided and exhibiting an appliance to be employed in its administration. In the discussion the necessity of a preliminary examination of the patient was emphasized and the use of adrenalin to overcome the effect of chloroform in extreme cases was mentioned.

Secretary's Report.

Dr. William M. Perkins, New Orleans, recording secretary, reported that the active membership of the society was 420.

New Constitution.

The discussion of the constitution was taken up, and Dr. Charles Chassaignac, chairman of the Committee on Revision, presented a draft of the constitution proposed by the American Medical Association. After considerable discussion, this was adopted with minor amendments.

President's Address.

At the evening session Dr. Isadore Dyer delivered the annual presidential address, his subject being "The Art of Medicine." After discussing medicine from the days when fetishes, charms, incantations, etc., were in vogue, he went on to say that medicine is still combating the weaknesses that hamper its progress, with the purpose, in the future, of conquering the great enemy, death. In conclusion he said:

> The profession of medicine has sat at the footstool of science, now and then gathering some of the leaves which have fallen from the hands of the alma mater of all knowledge. Again, some more emboldened spirit has snatched a full garland and has carried it off to render a proper return in advanced knowledge.
>
> One great man after another has died with the regret of neglected achievement, not fearful of death, but sad at leaving so much undone. A host of men have blazed the way for the art medical; many have dropped into the pool of forgetfulness the emblems of their trade and have lifted heavy burdens for the art itself; some have hewn long with small reward, while others have marked grand highways through the wilderness of ignorance and bigotry.
>
> It is not only the songs of the birds in the forest, nor the rustling leaves, nor the smell of freshness which makes the springtime, but without these things there could be no springtime. And so there must be in the art of medicine, of such kind as you will, but not barren, rather a fruitful one, carrying with it the sentiments of community of interests, of achievements, of earnestness, of fraternity, so that in the days to come we may think of the Temple of Hygeia and of the Great Healer as forever free of those sorts of death which are only evil shadows after all.

Yellow Fever.

Dr. Edmond Souchon, New Orleans, in his paper entitled "Facts Relating to the Transmission of Yellow Fever," detailed experiments with mosquitoes captured on fruit vessels coming from Central America, from which he drew the deduction that mosquitoes are not the only means of communicating the disease. This paper will appear in full in The Journal.

In the discussion Dr. J. M. Lindsley of Havana stated that he believed the mosquito was the primary means of transmitting yellow fever, and thought if the board of health at Havana had acted on this theory a few years ago many lives might have been saved.

Dr. Oliver L. Pothier supported Dr. Lindsley's views, and Dr. Souchon closed the discussion by declaring that, while he desired to be liberal, the ones who suffer must be considered when the question of exposure is brought up, and that leniency towards Cuba would be further extended when the health authorities were satisfied that the danger of transmission from yellow fever from that country had ceased to exist.

Quarantine.

Dr. Arthur Nolte, New Orleans, gave the history of the efforts to quarantine against yellow fever at New Orleans during many years and of the great results accomplished during the epidemics there. He detailed the present methods of disinfecting vessels.

Dr. Lindsley made a second appeal for impartiality in the enforcement of quarantine regulations between Cuba and other tropical countries.

Dr. Quitman Kohnke presented a very comprehensive history of Louisiana quarantine against yellow fever from the time of earliest legislation up to the present day.

Illegal Practitioners.

Dr. Charles L. Chassaignac, New Orleans, called attention to the reference in the report of the State Board of Medical Examiners to the prosecution of illegal practitioners in the state during the last year and urged that more rigor be used in guarding the profession.

Dr. A. Feltus Barrow, St. Francisville, president of the State Board of Medical Examiners, declared that he was not satisfied with the enforcement of the law and hoped that some decided action would be taken. He said that many students from Tulane University, on receiving their diplomas, fall into the hands of fakers of the profession who use them and their names to further their illegal practice.

Dr. Chassaignac stated that the difficulties attendant on prosecutions had been due to the lack of evidence and the lack of organization, and urged organization in the profession in order to accomplish the ends in view.

Pasteur Institute.

Dr. Charles L. Chassaignac introduced resolutions which were adopted without discussion, pledging the support of the members of the society to the establishment of a Pasteur Institute in New Orleans, and declaring in favor of the institute being made a part of the Tulane University, urging all physicians in the state to secure state and city and private donations; requesting the co-operation of the Orleans Parish Medical Society, and directing the president of the state society to appoint a member in each parish to supervise the movement therein.

Election of Officers.

The report of the Nominating Committee was adopted, whereby the following officers were elected: President, Dr. John M. Barrier, Delhi; vice-presidents, Drs. J. F. Buquoi, Pointe-a-la-Hache; John Callan, New Orleans; Frederick R. Tolson, Lafayette; Norwood K. Vance, Shreveport; S. L. Williams, Oak Ridge; Charles M. Sitman, Greensburg, and Arthur Gardner, Bristol; recording secretary, Dr. William Perkins, New Orleans; corresponding secretary, Dr. Andrew G. Freiderichs; treasurer, Dr. Henry S. Cocram, New Orleans;

delegate to the American Medical Association, Dr. Rudolph Matas, New Orleans; alternate, Dr. Louis G. LeBeuf, New Orleans, and additional delegate, Dr. Whyte Glendower Owen, White Castle.

1904 Meeting.

Lafayette was selected as the place of meeting for 1904, and the date May 3 to 5.

Banquet.

The local members tendered a banquet to the society at the West End Hotel, which was attended by over 200 guests. Dr. Quitman Kohnke was the toastmaster, and toasts were responded to by Drs. H. W. Foote, Ernest Lewis, Joseph Hart, Derold Wilders and Owen.

NEW YORK ACADEMY OF MEDICINE.

Regular Meeting of the Section on Pediatrics, April 9, 1903.

Henry Heiman, M.D., in the Chair.

Result of Operation for Intussusception.

Dr. **John F. Erdmann** reported three successful cases of operation for intussusception. The first was an infant of about four and a half months, first seen twenty-three hours after the onset of symptoms. Bloody mucus was passed per rectum, but no tumor could be felt. The operation revealed a double intussusception—an intussusception of the ileum within itself and an intussusception of the ileum within the colon. The appendix was not involved, but was removed after reduction of the intussusception.

The second patient was an infant of six months, in whom no tumor could be felt, but one was visible on the left side of the abdomen. There were continuous abdominal pain and bloody discharges. In this case also there was a double intussusception, and here the appendix was included.

The third patient was 5½ years old. There was no history pointing to intussusception and no fever, but there was continuous pain in the abdomen, with resistance in the right side of the abdomen. An ileocolic intussusception was found and was reduced.

DISCUSSION.

Dr. **H. Lilienthal** said that, while recovery occasionally followed the employment of hydrostatic pressure, this method was decidedly dangerous—indeed, no case of intussusception of sufficient severity to give rise to symptoms should be treated by other than surgical means.

Inversion in the Treatment of Acute Pulmonary Edema in Young Children.

Dr. **Thomas S. Southworth** reported the case of an infant, suffering from very severe and acute edema of the lung, wherein inversion and stroking pressure on the back gave prompt and marked relief by causing the discharge of much frothy mucus. The child had no cardiac disease, and the attack was supposed to have been induced by acute indigestion.

Pin Worms in the Appendix.

Dr. **J. F. Erdmann** exhibited an appendix containing numerous pin worms. The child had suddenly become acutely ill, and this was what was encountered at the operation.

DISCUSSION.

Dr. **Henry Heiman** said that the case was interesting because it was generally believed that the pin worms were only found in the rectum or descending colon.

The Surgical Features of Perforation of the Intestine in Typhoid Fever in Children.

Dr. **Charles A. Elsberg** presented a paper on this subject, in which he gave the results in the 289 operative cases on record. There were altogether 75 recoveries, or 25.9 per cent., and of the 25 patients who were under 15 years of age 16, or 64 per cent., recovered. Dr. Elsberg reported a recent case on which he had operated, which was, by the way, the youngest operative case on record, the patient being 6½ years old. About two weeks after the operation a vaginal discharge made its appearance, and in this was found a pure culture of typhoid bacilli. The frequency of intestinal perforation in children suffering from typhoid varied greatly in different series. Thus, Dr. J. Lovett Morse saw 284 cases of typhoid in children without once meeting with this complication, whereas Dr. Fitz met with it seven times in 192 cases. Holt collected 1,028 cases in children, and found that intestinal perforation occurred in 12, or 1.1 per cent. In practice it was well-nigh impossible to differentiate this complication from peritonitis.

The author's cases of operation were 25 in number, of which 14 were between 9 and 12 years of age. Eighteen of the patients were males, a fact difficult of explanation. It was noted that the facial expression changed in 11 cases, but that it never occurred early, and ordinarily not until other signs and symptoms had made the diagnosis of intestinal perforation reasonably certain. The pulse, respiration and temperature afforded little or no assistance in diagnosis, and although leucocytosis occurred at the time of the perforation, it was exceedingly evanescent, probably because of the great outpouring of the leucocytosis into the peritoneum when this membrane became infected. The first symptom in 20 cases was pain in the lower part of the abdomen, usually paroxysmal, and associated with or speedily followed by abdominal tenderness. Rigidity of the abdominal muscles was noted in 14 cases. The perforation most often occurred in the third week of the disease or in relapses.

The effect of delay in operating on the result was shown by the following figures regarding the interval elapsing between the occurrence of the perforation and the operation: Two cases operated on in the first four hours gave 100 per. cent. of recoveries; 3 cases operated on within the second four hours yielded 66.7 per cent. of recoveries; 7 cases were operated on within the third four hours with 71.4 per cent. of recoveries; in 3 cases the operation was done within the fourth four hours with 100 per cent. of recoveries; 1 case was operated on within the fifth four hours, and 1 in the sixth four hours without a recovery. Seven cases were not operated on until after the end of the first twenty-four hours, and here there were 57 per cent. of recoveries. In one of the fatal cases the interval was not known. The operation appeared from the statistics to be twice as successful in children as in adults, the most important element in the prognosis being rapidity of operating.

DISCUSSION.

Dr. **Lilienthal** said that he could vouch for the correctness of the diagnosis in the case reported in the paper in which a child had recovered from a typhoid perforation of the bowel without operation. The mortality rate given was probably too low, for it was more than probable that many of the unsuccessful cases had not been reported.

Dr. **Erdmann** suggested that the typhoid bacilli might have gained access to the vagina in the case reported as a result of the bursting of an abscess, or possibly by migration through the tubes and uterus

Dr. **M. Manges** pointed out that in children the occurrence of shock was apt to be overlooked because of the occurrence of fever, but it would be denoted by the presence of perspiration.

Dr **Heiman** said that a secondary anemia developing in the third week of typhoid might so depress the nervous system as to simulate intestinal perforation, and the same was true of the breaking down of a mesenteric gland. It was highly improbable that the typhoid bacilli could migrate through the tubes and uterus of a child of 6 years because of their rudimentary condition at that age.

Dr. **Elsberg**, in closing the discussion, remarked that, as all of the cases he had reported occurred in one year, it was quite possible that another year, with a different type of typhoid, might yield very different results.

Treatment of the Paroxysms of Whooping Cough by Pulling the Lower Jaw Downward and Forward.

Dr. **Jacob Sobel** said that this method had been first suggested years ago by a Swiss physician, O. Naegela, but had apparently been overlooked by most pediatrists. Dr. Sobel had tested the method in dispensary practice in 96 cases. In only 9 cases was there absolutely no effect on the paroxysm at the time of the child's visit to the dispensary. Very young children, not knowing the meaning of what was being done, were apt to become frightened, and by their crying neutralize the good effect of the manipulation. The physician, standing behind the child, should place both thumbs against the angles of the jaw, the index fingers on the zygomatic arch and the remaining fingers on the chin, and should then push the lower jaw downward and forward. The method had been devised in the belief that the essential element to combat was the spasm of the glottis. The spasm was so promptly controlled that it was not unusual for the whoop to be suppressed. In this way the mother or nurse could be taught to prevent the occurrence of many paroxysms, thus sparing the little one much nerve-racking distress, and, because of the control of vomiting, materially improving the general nutrition. The only contraindication was the presence of food in the mouth or esophagus. Dr. Sobel had not found the manipulation so useful in controlling other spasmodic coughs.

Dr. Charles Herrman said that he had tried this manipulation in a number of cases, and in most instances with a satisfactory result. Unfortunately, for the reason already mentioned, it was not very applicable to very young children. The method probably failed to relieve the spasm of the glottis occurring in tetany because, unlike pertussis, there was, in addition to the spasm of the glottis, a general spasm of the diaphragm and other respiratory muscles.

BOSTON MEDICAL LIBRARY ASSOCIATION.

Regular Meeting, held May 4, 1903.

Dr. W. T. Councilman in the Chair.

The Pathology and Etiology of Smallpox.

The meeting was devoted to a fuller statement of three of the phases of the subject, studied in connection with the purpose of finding the cause of variola.

THE BACTERIOLYTIC COMPLEMENT CONTENT OF THE BLOOD SERUM IN VARIOLA.

Dr. Ralph L. Thompson explained the terms "complement content" and "amboceptor," and stated Ehrlich's hypothesis, which is an explanation of individual immunity or susceptibility to infection.

The two great difficulties in the study are the method and the lack of any accurate knowledge of the nature or composition of the "complement" itself. His chief contribution is the discovery that another serum, for instance that of a horse, may be used as the amboceptor. This does away with the necessity of abstracting a large amount of blood from the individual, a few drops from the ear being quite sufficient, just as in the Widal tests. He has, hence, been able to study a large number of people, some being very severe cases of variola.

In all cases there is early a low "complement." Abortive cases and cases of true smallpox with all the stages but without complications have an early and rapid return to normal, beginning with the first involution of the lesions. Cases complicated with a secondary infective humor have always a low "complement," which may persist after the lesions have healed and the patient is well.

Much study is yet needed, but it would seem that this opens up a vast field for research, and is possibly a most important contribution to our means of making a more accurate prognosis.

EXPERIMENTAL STUDIES IN VACCINIA.

Dr. E. E. Tyzzer's experimental studies have been conducted on the lesions of vaccinia in the cornea of rabbits and calves. Vaccine virus introduced into the cornea of a rabbit produced a great proliferation of surrounding tissue, only a slight degeneration and a very evident formation of "vaccine bodies" which grew in size and number and invaded adjoining tissue. These disappeared in from six to eleven days. The same results were observed when variola virus from an early vesicle was inoculated into the cornea of the rabbit or from the cornea of an infected rabbit to another not yet infected.

He considered this strong evidence that there is the same cause for both variola and vaccinia. When the virus of either, however, is introduced into the cornea of a calf, much degeneration and no proliferation is produced, but the same "vaccine bodies" appear.

He then demonstrated the life cycle of these bodies by diagrams and lantern slides of photomicrographs. He believes this is the asexual cycle of a sporozoon. He stated the various other explanations offered for these vaccine bodies and that he had carefully considered each of them, with the result that he is confident that he has here a living growing body.

THE SKIN LESIONS IN VARIOLA.

Dr. W. T. Councilman explained the very definite nature of the course of variola and the care with which he and his associates have searched for the "protopustule" by which Pfeiffer endeavors to explain this definite course. No trace of any such pustule could be found. Nothing at all is known of the changes during the first twelve days, the period of incubation. Then we begin to get degeneration of the epithelial cells and the forcing out of fluid exudate. He showed a long series of lantern slides of photomicrographs of the skin in and near the lesions of variola from the first appearance of the papule to the condition of the scab.

He then demonstrated, as he did before the Boston Society of Medical Sciences, the peculiar bodies present in the cells of the deeper layers. He laid emphasis on the fact that during the intracellular cycle the cells were little if at all altered and the nuclei were normal. During the intranuclear cycle, however, degeneration of both is rapid. The same organisms are found in the beginning of both vaccinia and variola. Variola given to a cow will yield only the vaccinia cycle. But in man we get the second cycle, which is more complex and seems to correspond to the sexual cycle such as takes place for the malaria germ, within the mosquito as host. In the monkey, too, both cycles are obtained.

There is yet much to be done to work out completely this sexual cycle. Many of these observations were only made clear by the study of the photomicrographs of stained specimens. It has a complicated history and a complicated structure.

The organism has not been cultivated outside of the body, nor has it been observed before the appearance of the papule. Once the spores have been found in a blood vessel, suggesting thus the method of the dissemination of the disease.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Treatment of Acute Gout.

J. R. Clemens, in "Med. News," states that in the treatment of acute gout general consideration must be given to the medicinal, dietetic and local treatment. Elimination must be kept up by means of mercurials, salines and diuretics. Unless there are indications to the contrary, the treatment should be begun by the administration of pilula hydrargyri gr. iv (.25) followed several hours later by two ounces (60.) of mistura sennæ comp. in order to relieve hepatic congestion. The following mixture should then be prescribed, and continued until the motions become very free:

℞.	Magnesii sulph.	ʒiss	6	
	Magnesii carb.	gr. xxx	2	
	Pot. citratis	gr. xxx	2	
	Tinct. colchici sem.	m. x		65
	Aq. menth. pip. q. s. ad	℥i	30	

M. Sig.: To be taken at one dose and repeated every four hours until the movements are free, then less often. The colchicum should be continued until all the pain in the joint has disappeared, care being observed not to produce nausea, vomiting, etc.

The patient should be told to drink freely of hot water. The local treatment of the joint, according to the author, is most important. Warmth to the joint is very essential. As a local application the following is recommended:

℞. Sodii carb.	ʒiii	12
Tinct. opii	℥ii	60
Linimenti belladon.	℥ii	60
Aquæ q. s. ad	℥viii	240

M. Ft. lotio. Sig.: Mix part of the lotion with an equal quantity of hot water and apply to the joint on linen well saturated as hot as can be borne by the patient.

Around the dressing a yard of thin rubber should be placed, and over this a thick dressing of cotton wool held in place by a roller bandage. The limb should then be elevated, resting on pillows. Cold should never be applied to the joint. The diet for the first day or two should consist of milk, as follows: Bread and milk; tea boiled with milk instead of water; milk puddings of tapioca, sago, rice; milk and arrowroot. After convalescence the diet may be made more liberal. The following articles should be avoided: Salt meats and salt fish; shell fish (except oysters); all rich pastries and sweets; soups of all kinds; pickled foods; the four vegetables, tomatoes, asparagus, rhubarb, green peas. Beers and wines should be avoided, as well as salt and sugar, except in small quantities. Massage should be given to the joint. The following mixture is of service as a tonic and prophylactic, and should be continued for two or three months:

℞. Potass. iodidi	gr. x	65
Spts. ammon. arom.	m. xv	1
Inf. gentianæ co. q. s. ad	℥i	30

M. Sig.: At one dose after a meal and repeated thrice daily.

F. L. Satterlee recommends the following in the treatment of gout and rheumatism:

℞. Lithii benzoatis	ʒss	2
Sodii brom.		
Potassii carb., āā	ʒii	8
Potassii acetatis	℥iss	45
Sodii phos.	℥ss	15
Syr. zingiberis		
Aq. menth. pip., āā	℥vi	180

M. Sig.: One teaspoonful to a tablespoonful in half a glass of water every four or six hours after eating.

"Merck's Archives" recommends the following in the treatment of acute gout:

℞. Sodii salicylatis	ʒiv	15
Sodii nitratis	ʒiiss	10
Vini colchici rad.	ʒiiss	10
Aq. destil.	℥ii	60
Syrupi simplicis	℥iii	90

M. Sig.: One tablespoonful every four hours; or:

℞. Ichthyol	ʒi	4
Ext. belladonnæ	gr. x	65
Collodii	℥i	30

M. Sig.: To be applied externally with a brush, three times daily. And in chronic rheumatism the same periodical recommends the following:

℞. Sodii iodidi	ʒii	8
Vini colchici rad.	ʒiv	15
Sodii salicylatis	ʒiii	12
Tinct. guaiaci	℥ii	60
Syr. sarsap. co. q. s. ad	℥vi	180

M. Sig.: One dessertspoonful three times a day; or:

℞. Acidi salicylici	ʒii	8
Ichthyol	ʒiv	15
Ung. belladonnæ	ʒiv	15
Lanolini	ʒiv	15

M. Sig.: To be applied locally three times a day and thoroughly rubbed in; or:

℞. Aq. ammon. (concentrated)	ʒiv	15
Olei cajuputi	ʒi	4
Tinct. belladonnæ	℥i	30
Linimenti camphoræ q. s. ad	℥viii	240

M. Sig.: To be rubbed in thrice daily.

Salicylic Acid in Milk.

P. Schmidt, according to an abstract in "Indian Med. Record," states that the addition of a small quantity of salicylic acid to milk causes the milk to be tolerated by patients who otherwise are nauseated by its taste. From three to seven grains (.20-.50) of the salicylic acid are placed in a small quantity of milk and well stirred, this in turn is put in the quantity to be used in the twenty-four hours. The entire amount is raised to the boiling point; treated in this way the milk does not coagulate as coagulation will take place only when the proportion of salicylic acid exceeds gr. 4 (.25) to the quart. This is used in feeding infants, reducing the amount of the acid to one and a half grains to the quart.

Pertussis.

The following, according to the "Amer. Jour. of Obs." is of service in the treatment of pertussis:

℞. Tinct. stramonii sem.		
Am. bromidi, āā	ʒii	8
Elix. simplicis q. s. ad	℥ii	60

M. Sig.: One teaspoonful to a child of five years in water every two or three hours as may be necessary to quiet the cough.

The after-treatment should consist in giving ammonium carbonate gr. 2½ (.15) every three or four hours as an expectorant, administered in a little whiskey and milk. The foregoing prescription should be given sufficiently often to control the cough.

Preventive Treatment of Pericarditis.

According to Carriere, in "Amer. Med.," the heart should be watched in all infectious diseases which are liable to cause pericarditis. If rheumatism is contracted, treatment should be carried out energetically. The following combination is recommended, to be continued for three or four days:

℞. Sodii salicylatis	gr. xv-xlv	1-3
Syrupi aurantii	℥i	30
Aquæ	℥iii	90

M. Sig.: To be given during the twenty-four hours.

[The foregoing dose of sodium salicylate is frequently repeated as often as every two or three hours. The dose given would be too small for an adult.]

In other infections, in children, the following containing quinin is recommended:

℞. Quininæ hydrochlor.	gr. i-ix	06-.60
Glycyrrhizin	gr. xlv	3
Syrupi	ʒiiss	10
Aquæ	℥ii	60

M. Sig.: To be taken in tablespoonful doses during the twenty-four hours.

The importance of rest is emphasized. Cold to the precordial region and blistering below the clavicle are good prophylactics against cardiac and pericardiac complications, and should be applied in such cases.

Quinin Subcutaneously.

Aufrecht, in "Ther. Monatsh.," recommends that quinin be combined with urethane in order to render it more soluble, when it is desired to introduce the quinin hypodermically. The following combination is used by him:

℞. Quininæ hydrochlor.	gr. viiss	50
Urethane	gr. iiiss	20
Aq. destil.	ʒiss	6

M. Sig.: To be used at one injection hypodermically.

He uses this method of medication in pneumonia and puerperal fever, injecting it into the sides of the abdomen. The ill effects of quinin are observed in a much milder degree than when administered by the mouth.

Exophthalmic Goiter.

G. R. Murray, in "The Lancet," states that any drug treatment should be persisted in for several months. He recommends convallaria in those cases where the pulse remains persistently high. Belladonna does not act well in every case, but is of great value in some of these cases. He states that the bromids should be employed when marked nervousness and tremor accompanies the trouble. He also recommends arsenic in the form of Fowler's solution, giving three or four minims three or four times a day for a month or two. Thyroid extract should not be used.

Purulent Conjunctivitis.

G. C. Savage, in "Southern Pract.," states that conjunctivitis occurring within the first three days after birth should be considered as the result of infection and should be treated as such. Two drops of a two per cent. solution of silver nitrate or of a 10 per cent. solution of protargol should be put in each conjunctival sac. This should be done without waiting for pus formation and repeated on the following day. The silver solution should not be continued unless pus should appear, under which circumstances it should be used daily. The eyes should be thoroughly cleansed every half hour with a boric acid solution in order to prevent infection of the deeper layers of cornea.

Every two hours, after cleansing, the author recommends that eight or ten drops of the following solution be instilled into each eye:

℞.	Hydrastin sulph.	gr. ii	12
	Tinct. opii	m. xx-xxx	1.30-2
	Acidi boracici	gr. xv	1
	Aq. destil.	℥i	30

M. Sig.: Eight or ten drops to be instilled into each eye every two hours and continued until the eyes are well.

Cold should never be applied to the eyes.

Backache in Women.

Fenwick, according to an abstract in "New York Med. Jour.," states that there are four principal causes for backache in women:

1. Displacement of the uterus, the pain being due to the dragging on the uterine ligaments. The author recommends in many such cases the use of the Hodge or Zwancke pessary.

2. Pressure on the sacral nerves, due to constipation very frequently. In such cases he recommends the following:

℞.	Ferri phosphatis	gr. ii	12
	Ext. belladonnæ	gr. 1/4	015
	Ext. nucis vomicæ	gr. 1/4	015
	Ext. cascaræ sagradæ	gr. ii	12

M. Ft. pilula No. i. Sig.: One such to be taken three times a day after meals.

3. Muscular atony. The pain is located in lumbar and dorsal regions and found in anemic individuals with sedentary habits.

4. Affections of the cervix uteri, under which circumstances the treatment is surgical.

Medicolegal.

No Donation for Extra Services in Smallpox Epidemic.—Section 4424 of the Compiled Laws of Michigan directs that when there is any person in a township infected with the smallpox or other sickness dangerous to the public health the township board of health shall take needed action for the safety of the inhabitants, at the charge of the county when the person himself or the person liable for his support is not able to pay for same: "Provided, that the health board shall keep and render an itemized and separate account of expenses incurred in so caring for each person." It was suggested, in the case of the Village of Durand vs. Board of Supervisors of Shiawassee County, that this provision was directory to the board of health simply. But the Supreme Court of Michigan does not so regard it. It holds that the language of the clause is that of a proviso, and a proviso which affects the whole of the preceding section. And where, after a health officer had rendered a bill for specific services rendered in connection with an outbreak of smallpox and had received his pay therefor, the village paid him an additional sum for "extra services as health officer" during such epidemic and sought to recover the same from the county, the court declares that, however equitable the claim may have been as against the village, this statute certainly never contemplated that boards of health could bind the county by voluntary donations over and above the charges preferred by those having charge of these cases. The village had met the payment of this bill, and the court adds that it sees no reason why it should not bear the expense which was voluntarily incurred.

Death from Eating Unsound Oysters.—Unsound oysters produced the death of a man carrying an accident insurance policy by passing out of the large part of the stomach, lodging in the lower part of the stomach or upper intestine, inflaming the intestinal tract and mucous membrane, causing the same to enlarge, locking the bowels, obstructing and preventing passage, and thereby producing death. The company claimed that the policy exempted it from liability for "injuries, fatal or otherwise, resulting from poison or anything accidentally or otherwise taken, administered, absorbed or inhaled," and that the act of the insured in eating the oysters fell within the terms of said provision; that he ate them voluntarily, consciously and intentionally; therefore, they were not "accidentally" taken. But the Court of Civil Appeals of Texas holds against the company. It says, Maryland Casualty Company vs. Hudgins, that it was true the insured knowingly ate the oysters, but he did not know that he was eating unsound oysters. The effect was not the natural and probable consequence of eating sound oysters, and the effect produced by the eating of the unsound oysters could not have been reasonably anticipated or foreseen by him. It was unexpected, unforeseen and unusual, and, therefore, it could not be said that he voluntarily ate the unsound oysters. This being true, his death was caused by "accidental means," as that term was used in the policy. Furthermore, if it should be conceded that the court's position on this proposition was not sound, which it does not do, it says that it is still of the opinion that the word "anything," as used in the language "poison or anything accidentally or otherwise taken, administered, absorbed, or inhaled," did not refer to eating of food ordinarily harmless, not knowing it to be unsound and dangerous in that condition. It must be interpreted as having reference to those agencies which are not strictly denominated poison, but which have some elements of poison, and which may produce death if improperly taken.

May 2.

1 *A Case of Perforated Ulcer in Typhoid Fever. James C. Wilson and George G. Ross.
2 *Report of a Case of Painless Amputation of the Leg After the Intraneural Injection of Cocain. John H. Gibbon.
3 *Practical Points on Pessaries, Many Old, Some New. A. Ernest Gallant.
4 *The Radical Cure of Inguinal Hernia in Infants and Young Children. Charles G. Cumston.
5 *The Paradoxical Reaction of the Pupil in Accommodation, with a Report of Three Cases. William G. Spiller.
6 *A Study of the Brain-Weights of Men Notable in the Professions, Arts and Sciences. Edward A. Spitzka.
7 A Case of Endothelioma Occurring Within the Nasal Fossæ. Wm. Hitschler and George B. Wood.

1. **Typhoid Perforation.**—In Wilson and Ross' case the patient was nervous and restless and perspired freely eighteen to twenty hours prior to the probable time of the accident, and they ask whether the ulcer as it approached the peritoneal coat could not cause a vasomotor disturbance sufficient to account for the symptoms. When the perforation occurred the initial pain was referred to the penis and persisted there for twelve hours without being referred to the abdomen. The question is asked whether this pain could be due to the proximity of the inflammatory area to the ureter or bladder. There was a lack of collapse, the temperature remained high, no syncope, no vomiting, sweating or pain in the abdomen. Besides the unavoidable delay in making the physical diagnosis there was difficulty in securing consent for the operation, and hence the loss of valuable time. The patient died three hours after the operation with purulent peritonitis.

2. **Intraneural Injections of Cocain.**—Gibbon reports a case of painless amputation with good results under anesthesia pro-

duced by giving 1/4 gr. of morphin and 1/150 gr. of atropin hypodermically 15 minutes before the operation, and then exposing the sciatic and anterior crural nerves under infiltration anesthesia with Schleich's fluid and injecting them with a 1 per cent. cocain solution. The patient felt no pain and did not know that his foot had been amputated until the operation was finished. There was no evidence of shock, excepting a slightly increased pulse rate. Gibbon gives it as his belief that this method of producing anesthesia should be limited at this time to cases in which general anesthesia is contraindicated, but it certainly seems to him to have a wide field in the future practice of surgery.

3. **Pessaries.**—Gallant describes the conditions helped by the use of pessaries and the methods of their employment. He suggests the following precautions:

> When the pessary is in position (*a*) the vaginal wall should never be tense; (*b*) the lower bar must lie just behind the symphysis, invisible at the vulva; (*c*) it should be somewhat movable up and down and free from discomfort during coitus; (*d*) the wearer should not at any time feel conscious of its presence; (*e*) it must be removed at the end of the first week and the vagina examined for pressure points or any signs of irritation; it should then be replaced, and again removed at least once every four weeks, cleaned, polished with a dry towel, and reinserted; (*f*) the wearer must use daily a warm douche, to which may be added a tablespoonful of common salt, or two teaspoonfuls of sodium bicarbonate. These vaginal douches are of service only for cleansing purposes. Vaginal douches for the reduction of pelvic inflammation are injurious if not continued for at least 20 minutes, whereas rectal injections or continuous irrigations for an hour, once or twice daily, will exert an almost marvelous effect on recent pelvic inflammation, and in alleviating pain and tenderness, and for removing exudates in the old cases. For rectal injections he uses 2 quarts of water at 120 deg. F., to which have been added 2 ozs. hamamelis; the patient lying on her right side, her hips raised as high as possible and the legs flexed on the abdomen; allow the mixture to run in slowly, a few ounces at a time; encourage her to retain it as long as possible and lie still for an hour. In many instances the whole two quarts will be retained and will do her good. For continuous irrigation Kemp's tube has afforded the most satisfactory results.

No absolute cure of uterine displacements should be promised, but only symptomatic relief, and pessaries ought never to be used when there is present purulent vaginitis or fixation of the uterus, ovaries or tubes, pus tubes or pelvic enlargements.

4. **Hernia in Young Children.**—Cumston reports operations in children under two years old presenting different clinical phases, in two of them strangulation had taken place; one had a double hernia. All the children, with one exception, were in good physical condition and stood the operation well. No hard and fixed rules, he says, can be laid down as to the indications for radical cure. The most important one is strangulation. He does not believe in taxis in such cases. The Bassini operation has always been satisfactorily performed within one-half hour or less in his experience. He formulates the following conclusions:

> 1. Experience has demonstrated the innocuity of radical operation for hernia in infants. 2. The operation is indicated in all cases of strangulation, in all cases in which the contents of the sac can not be retained by a truss, and in every case in which irritation of the skin is produced by the mechanical appliance, and in children of the poor who can not receive the necessary and proper attention at their homes.

5. **Paradoxical Pupillary Accommodation Reaction.**—Three cases of this peculiarity are noticed by Spiller, in one of which there was unquestionably organic disease, though Piltz has said that it occurs only in functional disorders. The condition as understood is not the same as the better-known paradoxical reaction to light where the pupil becomes dilated under light stimulation. The condition here considered occurs only after accommodation.

6. **Brain Weights.**—Spitzka has collected 114 cases of brain weights of prominent individuals, of which 96 were suitable for analysis. He leaves out any mythical or complicated cases, and those to which valid objections could be made, and remarks in regard to the conditions as indicating atrophy or change from the actual condition during life. He finds there is a relatively greater number of heavy brains among noted individuals, as shown by the diagram he gives, and the average brain weights were higher in the United States and Canada than in Europe, in the individuals analyzed. The cases are tabulated according to the occupations, which show that the exact sciences, such as mathematics and astronomy, furnished men of heaviest brains, and next come the men of action, statesmen, politicians and military men. The creative arts come next, including among others three opera composers. The average of 45 representatives of the natural sciences is lowest of all, but still above the average of ordinary brain weights. While every rule has its exceptions, the inference that the intellectual status is in some way reflected in the mass and weight of the brain seems generally correct, but men devoted to higher intellectual occupations involving the most complex mental mechanism, those of men who have devised original lines of research and those of forceful characters are generally the heaviest.

8 *Indications for Extirpation of the Gall Bladder. Maurice H. Richardson.
9 *Some Practical Points in the Anatomy of the Gall Bladder Region. George E. Brewer.
10 *The Diagnosis of Gallstones. J. B. Murphy.
11 *The Mortality in Appendicitis; Its Cause and Limitation. A. J. Ochsner.
12 *Prompt Operation in the Beginning of the Attack Will Save Nearly All Cases of Appendicitis. A. C. Bernays.

8. **Cholecystectomy.**—Richardson is not an advocate of routine cholecystectomy, but points out its advantages in immediate healing and consequent lesser liability to hernia, the absence of any possibility of gallstones forming in the bladder or of a subsequent cholecystitis or malignant growths, and the minimum possibility of adhesions. On the other hand, there is no possibility of draining the biliary passages except through one of the ducts and that only after a difficult and usually unsatisfactory operation. In this lies the chief objection to cholecystectomy, for enforced and persistent drainage is one of the chief factors in bringing about the brilliant and permanent results seen after cholecystotomy. In most biliary affections, drainage is not only an advantage but an absolute necessity, and in removal of the gall bladder we dispense with an essential feature of the majority of cases of biliary surgery. There is also a greater danger in the operation. He sums up his conclusions as follows:

> 1. Certain lesions in themselves demand removal of the gall bladder whenever possible. Such are new growths and gangrenes.
> 2. Certain other lesions of the gall bladder are better treated by cholecystectomy. These are the contracted and inflamed gall bladders, with thickened walls. All gall bladders which do not permit easy and efficient drainage should be extirpated, for in such gall bladders the risks of drainage are quite as great as the risks of extirpation; and the one great advantage of retention is impossible—retention of the biliary reservoir to fulfill the functions of that reservoir, and to permit, if necessary, renewed drainage in future years.
> 3. Drainage is preferable in the dilated and infected gall bladder, which, however, is neither gangrenous nor to any great extent changed—the slightly thickened gall bladder containing gallstones and infected bile. This gall bladder will, after drainage, become normal, and therefore capable of fulfilling the functions of a gall bladder. Through it the biliary passages will become effectually drained, after subsidence of the temporary swelling about the cystic duct.
> 4. As a rule drainage rather than extirpation is demanded in acute cholecystitis with severe constitutional symptoms, when the gall bladder is dilated, or at least not contracted, and when it is not gangrenous.
> 5. In chronic cholecystitis, with dilatation and thickening of the gall bladder, especially when a stone is impacted in the cystic duct, extirpation is the preferable operation, unless the stone can be dislodged backward into the gall bladder, in which case drainage is, if not preferable, quite as advantageous as extirpation.
> 6. In simple gallstones, without visible evidence of infection or chronic changes incompatible with complete restoration of function, simple drainage of the gall bladder is indicated.
> 7. In chronic pancreatitis, whether associated with gallstones or not, drainage through the gall bladder is indicated. Cholecystectomy is unjustifiable, for immediate drainage is essential. Furthermore, reopening of the biliary passages may in the future be required.

9. **The Gall-Bladder Region.**—Brewer describes the anatomy of the bladder, its anomalies such as its absence, duplex gall bladder, variations in the ducts, etc.

10. **The Diagnosis of Gallstones.**—Murphy analyzes the various symptoms of gallstones, the pain, colic and their causes, vomiting, hypersensitiveness in the region, temperature, etc. In the relation of jaundice to pain, he formulates the following: 1. That jaundice due to gallstones is always preceded by colic; 2, that jaundice due to malignant disease, or catarrh of the ducts accompanied by infection, is never preceded by colic. The different classes of cases of gall-bladder infection are noticed, such as that characterized by pain,

vomiting, the types with characteristic recurrent chills, temperature, etc. The symptoms of stone in the common ducts and in the other ducts are all noted in detail.

11. **Appendicitis.**—Ochsner reiterates his views in regard to the management of appendicitis and the cause of its mortality, illustrating them by cases from practice. He considers that the mortality depends on the extension of the infection to the peritoneum and by metastatic infection, which can be prevented by removal of the appendix, while the infection is still confined to it. The distribution or extension of the infection is accomplished by the peristaltic action of the small intestines and also by operation after infectious material has extended beyond the appendix and before it has become circumscribed. He would fight peristalsis of the small intestine by prohibiting the use of every form of nourishment and cathartics by the mouth, using gastric lavage in order to remove any food or mucus from the stomach, and nourishing the patient for the necessary period of time by nutrient enemata. In this way dangerous cases of acute appendicitis can be changed into relatively harmless cases of chronic appendicitis, and the mortality following operations for the latter is exceedingly low. He offers the following suggestions:

1. Patients suffering from chronic recurrent appendicitis should be operated on during the interval.

2. Patients suffering from acute appendicitis should be operated on as soon as the diagnosis is made, provided they come under treatment while the infectious material is still confined to the appendix, if a competent surgeon is available.

3. Aside from insuring a low mortality this will prevent a series of complications, mentioned elsewhere in his paper.

4. In all cases of acute appendicitis without regard to the treatment contemplated, the administration of food and cathartics by mouth should be absolutely prohibited.

5. In case of nausea or vomiting or gaseous distention of the abdomen, gastric lavage should be employed.

6. In cases coming under treatment after the infection has extended beyond the tissues of the appendix, especially in the presence of beginning diffuse peritonitis, conclusions 4 and 5 should always be employed until the patient's condition makes operative interference safe.

7. In case no operation is performed, neither nourishment nor cathartics should be given by mouth until the patient has been free from pain and otherwise normal for at least four days.

8. During the beginning of this treatment not even water should be given by mouth, the thirst being quenched by rinsing the mouth with cold water and by the use of small enemata. Later small sips of very hot water frequently repeated may be given and still later small sips of cold water. There is danger in giving water too freely.

9. All practitioners of medicine and surgery, as well as the general public, should be impressed with the importance of prohibiting the use of cathartics and food by mouth in cases suffering from acute appendicitis.

10. It should be constantly borne in mind that even the slightest amount of liquid food of any kind given by mouth may give rise to dangerous peristalsis.

11. The most convenient form of rectal feeding consists in the use of one ounce of one of the various concentrated liquid predigested foods in the market, dissolved in three ounces of warm normal salt solution, introduced slowly through a soft catheter, inserted into the rectum a distance of two to three inches.

12. This form of treatment can not supplant the operative treatment of acute appendicitis, but it can and should be used to reduce the mortality by changing the class of cases in which the mortality is greatest into another class in which the mortality is very small after operation.

12. **Appendicitis.**—Bernays pleads for early operation. The absence of a tumor is a more pressing indication for immediate surgical interference than its presence. Whenever an operation for appendicitis is performed within twenty-four hours after the attack, it is successful in about 98 per cent. of all cases thus treated. He does not like these to be called early operations; they are only operations done at the proper time. The mortality of interval operations is also very low. He has had no deaths in over 400 cases, and as regards any special dangers in early operations, aside from the greater danger of the anesthetic in a few cases, he would say there are none. Operations done during the first day or two are easier and more complete than later operations. The whole answer to the question as to when to operate, is that we must operate early in the attack.

13 Address to the Nurses Graduating from the Framingham Hospital in 1902. Arthur T. Cabot.
14 *Albumosuria. Chauncey R. Burr.
15 A Case of Juvenile Aortic Stenosis, with Subsequent Insufficiency, Sudden Death: Autopsy. Albert N. Blodgett.
16 Mountain Sanatoria for Tuberculosis. Walter Lindley.

14. **Albumosuria.**—Burr described albumosuria and the conditions in which it occurs and insists on the importance of the fact that, aside from lesions of the digestive tract, albumosuria is indicative of leucocytosis and peptonuria of pus absorption. He describes the tests, the only sure one being the saturation of urine at the boiling point with neutral ammonium sulphate; filter and wash the precipitate with saturated solution of ammonium sulphate. Dissolve the precipitate in water or dilute sodium chlorid solution and apply the biuret test. If albumoses are present a rose color results. The treatment is based on the indications mentioned above.

17 *Cranial Form in Man, Together with Some Remarks on the Attitude of the Profession Toward Anthropology. Arthur Thomson.
18 *Reciprocity in Pathology. S. B. Laache.
19 *Antituberculous Campaign in Latin America. Emile R. Coni.
20 *The Expansion of a Specialty. Howard A. Kelly.

17. **Cranial Form in Man.**—The agencies operative in modifying the cranial form are stated by Thomson under two heads: 1. Those operative from within; 2, those operative from without. Considering all the facts, the increased size of the temporal muscle coincides with a greater development of the jaws and he finds a correlation between the coronoid index and the cephalic index, the higher coronoid index being usually associated with dolichocephaly while the lower coronoid indices are met with in skulls of the brachycephalic type. This, however, is from a comparatively small number of observations, and further study is required. Prolonged stress in the region of the pterion, by enlarged temporal muscles, has its effect on the contour of the cranium. Passing on to the consideration of the causes operating from within, he notices the work of Papillault, who has shown that the occurrence of the metopic suture is more common among races with large cranial capacity, and is due to a superiority in the bulk and relative weight of the cerebrum. He also refers to the observations of Boas, who has established that the height of the skull seems most closely associated with capacity, the length least so. To determine the effect of pressure from within, Thomson contrived an apparatus consisting of a rubber bladder fastened over the base of the skull with cords cemented to it representing the temporal muscles, to which could be attached weights. The varying degrees of the distension of the bladder illustrate the different types of the skull. His main point has been to prove that the shape of man's head in its highest development is the outcome of physical and intellectual environment which have led, on the one hand, to a reduction in the size of the jaws and on the other to increased volume of the brain.

18. **Pathologic Reciprocity.**—Laache's article is a consideration of the relations existing from a clinical point of view between the different organs and systems of organs.

19. **The Antituberculous Campaign in Latin America.**—Coni gives the history of the efforts made against tuberculosis in the Spanish and Portugese-speaking regions of the western continent.

20. **The Evolution of the Specialty.**—Kelly's article is an endeavor to show that while there exists a historical continuity in the use of the term gynecology, modern practice differs *toto coelo* from that of former times. The change is not a natural evolution, but an absolute transformation from a minor specialty to a general specialty of major surgery. The term gynecology, he thinks, is a misnomer to-day.

27 The Society [illegible] Biology and Medicine. William J. Gies.

21. **Infantile Diarrheas.**—Morse describes the different types of bowel trouble in infants, the simple diarrheal, which is usually relieved by early removal of the cause, the infective diarrheas due to micro-organisms, to which he gives the name fermental diarrhea, ileocolitis and cholera infantum. In the fermental form the best treatment after purgation to remove the cause is to cut off all food for twenty-four hours, giving only sterile water and later employing a proteid diet with almost complete exclusion of sugar in cases of sour stools. In others, following the general principles and using milk preparations as soon as the stomach will bear them, but previously employing various substitutes which, he thinks, however, are largely effective through their weakness in nutritive material and consequent lack of taxing of the digestive organs. When beginning to use milk preparations, whey is often most useful, made either from whole or skimmed milk. It is prepared by adding a teaspoonful of essence of pepsin or a junket tablet to a pint of milk and heating to from 100 to 110 F. until it coagulates. Then strain through a napkin. A little cream may be added if the patient is doing well, heating first the whey to 150 F. to avoid curdling the cream. If whey is not used the infant should be given a modified milk prepared from fresh milk low in all percentages, highly alkaline and pasteurized. Breast feeding should not be forgotten. In many cases it will result in cure. For drugs he uses bismuth, preferring the ammoniocitrate. The special symptoms due to toxic absorption may require treatment; vomiting may be relieved by stomach washing, hyperpyrexia by cold bathing and the bromids be used for restlessness, and morphin if necessary; stimulants in cases of prostration and collapse, for which brandy and strychnin are most useful. The toxic symptoms are sometimes much relieved by subcutaneous injections of normal salt solution, which can be also given as an enema, though it is not likely to be retained. Ileocolitis, which has more serious pathologic lesions, must be treated along the same lines, but it is possible in this case to reach the seat of the disease from below and irrigation comes into play. Normal salt solution or 1 to 2 per cent. strength of boric acid are most useful. In some chronic cases weak irrigations of silver nitrate in the proportion of 1 to 1,000, one in two or three days, seem to hasten recovery. A strong salt solution should always be at hand when this is used in case its proves too irritating. In cholera infantum the main indications are to empty the stomach and bowels of their toxic contents, supply food to the tissues which are being seriously drained, restore surface circulation and reduce the temperature and keep the patient alive until the disease has run its course. He depends mainly on stomach washing and intestinal irrigations used early and vigorously, and stimulants given subcutaneously.

22. **The Uremic State.**—Stern calls particular attention to the retention nitrogen, that remaining in the blood after complete removal of albuminous substances, as having an important causative relationship to uremia. He considers the promotion of perspiration a very important measure in almost every case, though it is of little value after a pronounced comatose condition has supervened or the attack has persisted for a long time. Enteroclysis should also be performed with weak chlorid solution, or hypodermoclysis with a hypotonic solution of NaCl should be performed at certain intervals. In many cases venesection is of use, though it is bad in advanced asthenic conditions. Much stress is laid on the use of hypodermoclysis and infusion. An isotonic chlorid solution containing 0.9 per cent. of sodium chlorid is not quite as efficient in uremia as one which is slightly weaker, 0.6 per cent. The minimum amount used should never be less than 125 c.c. injected intravenously and 250 c.c. when administered by hypodermoclysis. It should be used slightly above the normal blood heat. When, after the employment of chloroform, vasoconstriction and convulsive phenomena do not diminish, a small dose of morphin may be resorted to and help to bridge over a critical period. It is not indicated, however, in uremia of chronic interstitial nephritis, which rarely shows convulsive phenomena, but is comagenous itself, and here it might hasten the fatal issue.

24. **Syphilitic Toxemic Hemiplegia.**—Burr describes the case of a young woman who, in recovering from a spree, suffered from a headache, became queer and dazed, and the next day fell unconscious and convulsed, the convulsive movements lasting many hours, the unconsciousness several days. During this time a slowly oncoming hemiplegia preceded by dilatation of the left pupil developed, and later there were changes in the reflexes and left-sided ptosis. Consciousness slowly returned and later hemiplegia and other symptoms, barring a slight pupillary disturbance, passed away. A study of the case excluded other causes such as hemorrhage, blood poisoning, etc., and the diagnosis of a syphilitic origin was made by exclusion. The only positive evidence of syphilis was the patient's endurance of the specific treatment, and the character of the symptoms.

26. **Peritonitis Without Perforation in Typhoid.**—The following are the conclusions offered by Yates after a discussion of the condition and detailed reports of cases:

1. Non-perforative peritonitis usually results from an extension of inflammation through the bases of deep intestinal ulcers, but may also arise from the migration of bacteria through an intestinal wall which is relatively but slightly abnormal.
2. Meteorism thus predisposes to infection of the peritoneal cavity and by decreasing the normal peritoneal absorption furnishes a secondary cause for peritonitis.
3. An hematogenous origin of peritonitis is possible in typhoid fever.
4. Non-perforative peritonitis is commonly caused by the typhoid bacillus and the resulting inflammation is usually diffuse and often severe.
5. The inception of such a peritonitis is clinically indistinguishable from the so called signs of perforation, and the symptoms in both are due to peritoneal inflammation. The prognosis is probably equally grave in the two forms.
6. There should be appropriate surgical intervention immediately the peritonitis can be recognized. Enterostomy is indicated when there is meteorism with the peritonitis or when it affects the prognosis and is intractable to ordinary therapeutics.
7. Thrombi, and among them those composed of agglutinated red blood-corpuscles, may lead to hemorrhages into the wall of the intestine and the resulting changes favor the transmigration of bacteria into the peritoneal cavity.
8. Infarction of the spleen may have a similar thrombotic causation, but simple splenic infarction is probably not a cause of peritonitis.
9. The specific action on human blood of an agglutinin generated by the typhoid bacillus can be demonstrated *in vitro*.

33 An Anastomosis Ring. William L. Keller.
34 Suprascrotal Operation for Varicocele, with Ligature of the Spermatic Artery. E. Styles Potter.

28. **Shortening of the Tendo Achillis.**—Hibbs reports several cases in which shortening of the tendon was performed on account of an earlier tenotomy and the loss of power of the calf muscles. The operation for shortening revealed dissimilarity in every particular of the structure filling the gap between the ends of the old tendon to normal tendon structure, which he thinks points out that subcutaneous division of the tendo Achillis is not always so successful as it has been considered; that while in some cases the reproduced structure seems to be sufficiently strong to perform the function of tendon, in others this is not so, and one can not be sure in any case what will be the result. There must be some conditions necessary for complete success and these are, he thinks: 1, the preservation of the sheath, and 2, the preservation of the continuity of the tendon. These can not be secured except by open operation.

30. **Gastric and Duodenal Hemorrhages.**—Einhorn discusses the treatment by rest in bed, abstinence from food, use of ice,

etc., as rational methods. He has had good results from the subcutaneous use of gelatin and would recommend it. Adrenalin is also of value, and he has experimented on rabbits to show its effects, which indicate a distinct value of the local application of the drug on the bleeding area. He has used it, injecting a solution of adrenalin chlorid, 1 to 2,000 subcutaneously twice daily in 2 cases of gastric hemorrhages, with apparently good results, and has also tried spraying the stomach with a 1 to 5,000 solution. Further clinical tests will be required. Heart stimulants must be employed in most cases of gastric and duodenal hemorrhage besides the other measures of avoidance of exertion, rational feeding, and using iron, arsenic, and bone marrow with the tentative use of gelatin and adrenalin. The indications for surgical intervention, excision or cautery of bleeding area or gastroenterostomy, are very profuse hemorrhages at short intervals; profuse gastric and duodenal hemorrhages occurring once or twice yearly and greatly endangering the life of the patient. These require the interval or prophylactic operation. Frequent small hemorrhages of the stomach or duodenum, which greatly debilitate the patient and can not be stopped by rational therapeutics, often demand operative measures and here gastroenterostomy is usually advisable.

31. **Suprarenal Extract.**—The uses of this drug are reviewed by Douglass, who finds it specially valuable in diminishing bleeding and hemorrhages during nasal operations. It has its limitations and possible drawbacks, and he has not seen much good from it in operations on the adenoid tissues. In hemorrhage after tonsillotomy, hydrogen peroxid seems to him to work better. The suprarenal has also its value in diagnosis, in differentiating congested from hypertrophied tissues. In acute inflammatory conditions of the nose, pharynx and larynx, it is one of the best remedies.

32. **Stenosis of the Larynx.**—Three cases are reported by Duel to emphasize the points made by Rogers in his paper in the "Annals of Surgery" for May, 1900, on the retained intubation tube. The principal points to remember are that about 1 per cent. of all patients intubated for acute laryngeal stenosis will "retain" the tube. This is due in most cases to chronic inflammation of the intralaryngeal mucosa and subglottic tissues, and is not the result of granulation or cicatricial bands, etc. Auto-extubation in these cases is the rule and greatly adds to the danger, and as a result of this tracheotomy is often performed for safety. Where high tracheotomies are done, cicatricial bands are almost certain to form in the trachea or lower part of the larynx above the tracheotomy wounds. The points in the treatment to be emphasized are the use of the largest possible sized tube under anesthesia. In case of contraction, rapid dilatation should be done by beginning with the small sizes and working up to the large special tube, which is to be left in place. This tube should be left in for at least six weeks and then removed, and in failure of recovery it should be replaced for six weeks longer. He is in favor of splitting the larynx and holding the tube in place by means of the retaining clamp early in such cases, rather than resorting to tracheotomy, which adds cicatricial bands to the already existing complications.

41 *The X-rays in Medical Diagnosis. Soren P. Rees.
42 So-called Chronic Catarrhal Endometritis. A. W. Abbott.

41. **X-Rays in Medical Diagnosis.**—Rees finds a decided value in the *x*-rays aside from their surgical use, not merely in the treatment of cancer, hypertrichosis, etc., but in medical diagnosis. The chest appearances are specially noted and the possibilities of determining tuberculous lesions, pneumonia, emphysema, pleurisy, where doubt exists, are pointed out. Any abnormality in size, shape, position or movement of the heart is readily discovered when the lung casts a normal or lighter shadow. A comparison between the outlines obtained by percussion and those by the fluoroscope shows what a material aid the latter is in determining the size of the heart. It has been shown that the apparent enlargement of the heart in cases of chlorosis is in many cases merely a change in the long axis of the heart from the vertical to the more oblique. Pericardial effusion, adhesions and displacements are apparent with a certainty that is otherwise impossible. In thorax aneurism and in the early stages of many aneurisms, when the prognosis would be most favorable if the condition could be ascertained, the *x*-rays come into special use, and deeply seated, enlarged glands, tumors, etc., are also detected. By means of a metallic sound or soft rubber tube filled with mercury or shot after its insertion, a diverticulum or stricture of the esophagus is demonstrated. The abdominal and pelvic organs do not show the same differences in density as in the thorax, and the ray is less satisfactory. Using certain precautions such as a brisk purge, freedom of the stomach from food, doing away with clothing, etc., much can be done, however, in determining conditions below the diaphragm. The importance of having a skilled physician to interpret the appearances is emphasized. Cases of calculus of the gall bladder, kidney and uterus, especially show the uses of the *x*-ray. Rees finishes with the following conclusions:

> 1. That the *x*-ray is a very valuable aid in the diagnosis of many medical diseases, and of primary importance in the diagnosis of several. 2. That for the internist, at least, who confines his work largely to chronic ailments, it becomes especially valuable, and that it is entirely feasible for him to make office examinations of suitable cases. 3. That the rapid improvement in apparatus and technic and the need of careful training on the part of the observer, will prevent for some time its successful employment by the ordinary practitioner. 4. That while we must admit an idiosyncrasy to the *x*-ray in some persons, the danger of burn to the operator and to the patient, if proper precautions are taken, is very small.

Journal of Tuberculosis, Asheville, N. C.

April.

43 *Pulmonary Tuberculosis. Aufrecht (Magdeburg).
44 *The Mode of Infection in Tuberculosis and Measures for Its Prevention. F. M. Pottenger.
45 Origin and Growth of Sanatoria for Tuberculosis in Massachusetts. Vincent Y. Bowditch.
46 *Auxiliaries in the Treatment of Consumptives. Otto Juettner.
47 Report of 309 Cases of Pulmonary Tuberculosis, with Remarks on Classification and Treatment Employed. Karl von Ruck.

43. **Pulmonary Tuberculosis.**—Aufrecht combats the ordinary idea of infection by inhalation and the dangers of the contagiousness of the disease. The method of its entrance into the system he holds is ordinarily through the tonsils and from these to the lymphatics and thence through the vessels to the lung tissue. There may be a formation of cheesy foci in the apex due to entrance of the bacilli into the smaller branches of the pulmonary artery as in ordinary chronic tuberculosis. In what he calls subacute pulmonary tuberculosis very numerous cheesy tubercles may occur throughout the whole lung tissue, caused by sudden invasion by hordes of bacilli through the pulmonary artery. Recovery in this form is still possible. Lastly, the pulmonary tuberculosis may be only a partial phenomenon of an acute general miliary tuberculosis traceable to overwhelming of the whole body by tubercle bacilli through the systemic circulation.

44. **Mode of Infection of Tuberculosis.**—Pottenger's views are much like those of Aufrecht as regards the mode of infection. He thinks that, in a very large proportion of the cases, the bacilli are taken into the body by the mucous membranes of the upper respiratory and digestive tracts. When once through the mucous membrane they find themselves in the lymph spaces, whence they are carried and deposited in the neighboring or some remote lymph gland, or find their way

through the thoracic duct into the pulmonary circulation, to be strained out by the small vessels of the lungs. He insists on the importance of precautionary measures against tuberculosis infection.

46. **The Treatment of Tuberculosis.**—Juettner discusses the methods of massage and chest gymnastics, oxygen and ozone inhalation, the use of high frequency currents, photo- and Roentgen-ray therapy and hydrotherapy.

Pediatrics, New York.

April.

48 *A Contribution to the Natural History of Diphtheria. H. Illoway.

48. **Diphtheria.**—Two cases are reported by Illoway. He offers certain conclusions, affirming that diphtheria is a self-limited disease and when placed under proper conditions tends to recover. Even grave dyspnea does not necessarily indicate a fatal issue; nature may work out its own salvation. Diphtheria following on measles is a grave affection, and all such cases in his experience as were tracheotomied or intubated, died. He concludes with the report of a case of tonsillar diphtheria which he finds has also the same natural tendency to recovery, though it may produce very marked constitutional disturbance with but trifling local manifestations. The case also points out the advantages of digitalis as a cardiac regulator and a controller of temperature.

52 The Rôle of the Cystoscope in the Diagnosis and Treatment of Some Diseases of the Urinary Tract. Charles P. Noble.
53 *Fistula between Gall Bladder and Stomach. A. Barr Snively.

50. **Tic Douloureux.**—Frazier offers a further report on the advantages of section of the sensory branch of the fifth nerve in place of extirpation of the gasserian ganglion in obstinate cases of neuralgia. He enumerates among the advantages claimed for division of the sensory root that it obviates a number of difficulties, especially hemorrhage, which is the greatest bugbear in gasserian extirpation. It usually occurs from three sources: 1. From the middle meningeal artery. 2. From the emissary veins. 3. From the cavernous sinus. As regards hemorrhage from the middle meningeal, the two operations are on a par, but as regards the other two sources of hemorrhage, section of the sensory root avoids hemorrhage, and the chances of injuring the adjacent structures are also very much lessened and there is a decided reduction in the rate of mortality.

51. **Unilateral Renal Hematuria.**—Eshner reports a case presenting symptoms of renal calculus with hematuria in which, after exposure of the kidney, nothing abnormal was found, but the symptoms disappeared permanently. He discusses the literature at length and gives a summary of the reported case, together with an analysis. He concludes that there occurs occasionally, in men and women alike, mostly at middle adult life, hemorrhage from a single kidney, from either with equal frequency, in many cases from demonstrable organic disorder and in others of obscure or unknown origin. This hematuria may cease after simple exposure of the kidney, or after nephropexy or nephrotomy or, in the failure of these, after nephrectomy.

53.—This article appeared in The Journal of April 11, p. 963.

59 A Tumor of the Dura Mater Covered by the Cerebellum, Located in the Posterior Fossa of the Skull; Some of the Symptoms Resulting Therefrom. William L. Bullard.

56. **Glaucoma.**—Peterman reports a case of malignant glaucoma which recovered. It was associated with astigmatism "against the rule" in both eyes, and the second eye became infected with glaucoma two years and three months after the first. Iridectomy was performed and malignant glaucoma did not occur. In conclusion he remarks on the effects of the salicylates in these cases.

57. **Amblyopia with Slow Recovery After Cataract Operation.**—Moulton reports two cases of amblyopia from disuse. The patients were operated on for cataract, but sight return was very gradual in spite of perfectly clear media and healthy fundus. Several months were required for perfect restoration.

58. **Prevention of Conjunctival Infection.**—In order to prevent infection of the corneal wound from the lachrymal passages, Ellett operated by incising the conjunctiva all around the cornea as in case of enucleation, then dissecting it up from the ball by means of a probe, care being taken to free it well in the upward and downward directions to a distance of about half an inch from the limbus. The cataract was extracted by the combined operation and the cut edges of the conjunctiva then picked up and drawn upward and downward until they met over the cornea and were united by a horizontal row of stitches so as to completely cover it. No apparent gap was left and iodoform was thickly dusted over the line of union and the eye covered with a light gauze dressing. The eye was irrigated every hour with boric solution and iodoform reapplied. After the fourth day, when the ball seemed to have regained its natural contour, the stitches were removed and the conjunctival edges spontaneously separated and the corneal wound was seen to have closed. The whole cornea was exposed about three days after the removal of the stitches, the conjunctiva attaching itself again in its normal position.

67 *Surgery of the Prostate. John B. Murphy.

60.—This article has appeared elsewhere. See The Journal of April 4, title 48, p. 937.

61. **Malarial Hematuria.**—Winstead holds that malarial hematuria is a toxemia due to retained poisons within the circulation which quinin has no power to eliminate. The malarial parasite is not its direct cause. Elimination of these toxins by the bowels and the kidneys is the first imperative duty in the treatment, afterwards fortifying the system against them by quinin and other tonics.

65. **The Nucleids.**—Larned reviews the literature of the nucleinic acid salts and offers the following deductions in conclusion:

1. These new salts of nucleinic acid are rational reconstructives; they are true tonics. They increase physiologic resistance: they increase the functional activity of the secretory organs. 2. They are powerful germicides, while not harmful but beneficial to the tissues. 3. If our present knowledge of nucleins and leucocytosis is correct, then the nucleid is the proper form for administration of metals. 4. We do not positively know the rationale of their action, but we have nothing which holds out such prospects for successful medication. 5. These new synthetic salts are valuable additions to the pharmacopeia.

66. **System in Medical Practice.**—Black's article is an elaborate description of a plan of keeping records and accounts according to the card system, following the Melville Dewey classification.

67. **Surgery of the Prostate.**—Murphy favors the perineal route in prostatectomy as less dangerous than the suprapubic

or Bottini operation, as less liable to cause hemorrhage, sepsis or injury to the neighboring structures, favoring drainage and rapid restoration, shortening period of wound repair, favoring retention of vesical control and relief of vesical irritation. The sexual power is destroyed. He reports a large number of cases, with numerous illustrations.

7 *Knock-out Blows. James G. Duncanson.

1. Gastric Cancer.—The symptoms, diagnosis, physical examination and treatment of gastric cancer are reviewed by Robson, who gives illustrative cases. He says he trusts he has advanced sufficient evidence to prove:

1. How desirable it is to make an early diagnosis of cancer of the stomach in order that a radical operation may be performed at the earliest possible moment. 2. That it may be needful to perform an exploratory operation in order to complete or confirm the diagnosis. 3. That such an exploration may be done with little or no risk in the early stages of the disease. 4. That even where the disease is more advanced and a tumor perceptible, an exploratory operation is, as a rule, still advisable in order to carry out radical or palliative treatment. 5. That, where the disease is too extensive for any radical operation to be done, the palliative operation of gastroenterostomy, which can be done with very small risk, may considerably prolong life and make the remainder of it much more comfortable and happy. 6. That some cases, thought at the time to be cancer, too extensive for removal may, after gastroenterostomy, clear up completely and get quite well. 7. That in cases of disease of the cardiac end of the stomach too extensive for removal, the operation of gastrostomy may considerably prolong life and prove of great comfort to the patient by preventing death from starvation. 8. That even where the disease is too extensive either for removal or for gastroenterostomy being performed with a fair chance of success, the operation of jejunostomy may occasionally prave of service to the patient. 9. That where a radical operation can be performed the thorough removal of the disease may bring about as much relief to the patient as does the operation for removal of cancer in the breast, uterus and other organs of the body, and that in some cases a complete cure may follow.

2. Gastric Ulcer.—In 500 cases of gastric ulcer treated at the London Hospital in 1897 to 1902 there were nearly 10 per cent. of deaths from peritonitis, 13, or 2.5 per cent., from hematemesis, and 5.5 per cent. from other causes, or a total of about, approximately, 18 per cent. out of the 500 cases. No less than 211 had suffered previously, about two-fifths of the total. Counting the 18 per cent. of deaths and 42 per cent. of relapses, the ratio of cures in a surgical sense could hardly be considered a high one. Moullin points out that operation in these cases is not only feasible but sufficiently safe to justify its recommendation. He has operated on 15 cases, with 2 deaths, and in some of these, operated on for hematemesis, the loss of blood was so great that transfusion had to be performed on the table or immediately after. He considers a logical classification of gastric ulcer impossible. In the acute cases there are two indications for operation, threatened perforation and hemorrhage. The former can rarely be diagnosed beforehand. One special symptom that indicates the spread of ulceration is persistent cutaneous hyperesthesia in Head's epigastric triangle, especially when combined with a similar condition of the corresponding dorsal point. This means something going on in the wall of the stomach sufficient to render the corresponding spinal nerve segment unduly sensitive. He would recommend exploration when this symptom is present. A single hemorrhage is rarely fatal. Bleeding will stop if the stomach is given absolute rest, but if the pulse rate continues to grow quicker and quicker and the well-known restlessness and yawning has set in, he recommends exploration. He would also follow the same plan for a second severe hemorrhage occurring within a few days of the first and when the hemorrhage, though comparatively slight, returns repeatedly.

7. Knock-Out Blows.—The general impression that there is only one knock-out blow, that under the jaw, is an error, according to Duncanson. Even with boxing gloves now used, there are a number of such blows, and some may even be fatal. The temple is especially vulnerable, and a blow there may be followed by laceration of brain substance with hemorrhage. A swinging short-arm blow on the ear may cause rupture of the tympanum, dizziness and collapse, and a dangerous blow may be delivered on the neck so that when the head is pushed back, the side of the neck being exposed, the gloved hand is driven forcibly on a spot midway between the angle of the jaw and the sterno-clavicular articulation (the carotid hit). Another point is just on the larynx or hyoid bone. The danger in these blows is in the concussion through the large and important nerve trunks. A severe blow delivered on the chest wall about the region of the heart may cause syncope and death, especially if the muscles of the chest walls are relaxed and the lungs not expanded. Diaphragmatic blows are not, as a rule, dangerous to life. There is collapse, with difficulty in getting breath and sometimes unconsciousness. Brisk rubbing, external warmth and, if necessary, stimulants are the best treatment. Blows over the kidneys are somewhat perilous, and a blow over the pit of the stomach or what is called the "mark," a special area the size of the palm of the hand and corresponding with the center of the triangle formed by the xiphosternal articulation above and a line joining the bony ends of the seventh ribs below, just over the pyloric end of the stomach. The effects are due, according to Edgeworth Johnstone, to irritation of the pneumogastric setting up cardiac failure. The pugilist speaks of knock-out blows over the solar plexus, but it is the stomach that receives the shock and from it the nerve disturbance originates. When a man is knocked out and does not speedily rally, the best treatment is to get him away from his surroundings as soon as possible, wrap him well in warm blankets in bed and administer stimulants—strychnia hypodermically if necessary. Of course, if more serious lesions exist, such as fracture, the treatment must be conducted on recognized surgical lines.

14 A Case of Acute Ependymitis in an Infant. J. A. Coutts.
15 A Case of Dropsy, the Result of Inflammation of the Kidneys, Treated by Laparotomy. Henry P. Planer.

9. Infective Endocarditis.—Glynn's third lecture reviews some of the symptoms, such as excessive perspiration, epistaxis, diarrhea, vomiting, albuminuria, hematuria, and splenic enlargement. The physical signs are also noted. The difficulties of diagnosis are sometimes insuperable. In the absence of positive signs, the diagnosis depends on ability to exclude all affections other than acute endocarditis, likely to cause pyrexia, though this method may sometimes fail. There is a resemblance to pernicious anemia in some cases. Recovery is rare and no specific remedy has been found. The success with antistreptococcus serum is not what was expected.

10. Dietetics.—Two well-defined conditions of proper diet are given by Hutchison as: 1. That the food yields enough potential energy to supply the daily outgoings in the form of heat and work. 2. That it contains enough proteid to replace the daily and inevitable destruction of tissues. Somewhere between 2,500 and 3,500 calories will be required; probably 3,000 represent the requirements of the ordinary town dweller, and part of this must be supplied in the form of proteid. Whether this is obtained mainly from carbohydrates or fat depends largely on the digestive capacities of the individual and, to some extent, on his purse, as fats are more expensive than carbohydrates. As to the amount of proteid required to supply the waste, there is not full accord. The 120 grams recommended by Voit is larger than is considered necessary in many cases, but we do not know the minimum below which one can not go with safety. The tendency to overeat is responsible for much disease. A food, giving a maximum of volume with a minimum of nourishment would be a godsend to many overfed persons. The excess of the proteid diet is principally responsible for much kidney and uric acid diathesis. One principle we must bear in mind is the interdependence of organs. We can not cut down the diet to treat a diseased stomach or kidney at the expense of the general nutrition. Ordinarily abrupt changes in the diet are to be avoided. He says there are only three great groups of diseases in which one can reasonably anticipate that dietetic means will be potent for cure. They are: 1. Diseases of the organs of digestion; 2, diseases of metabolism, fever, obesity, malnutrition, diabetes and gout where there is a perversion of the usual methods of dealing with nutrition, and 3, diseases of the excretory organs, especially the kidneys. As regards dyspepsia, Hutchison remarks that the mechanical form of food is always of more importance than its chemical composition. The meals of the dyspeptic should be small and contain no insoluble ingredients. The stomach should be humored to pass on the food. In most cases of functional disorder he thinks it well to give the stomach a little wholesome neglect. Overeating may be a serious evil. In bowel troubles we should consider the mechanical condition of the food. One should select a diet in diarrhea that has as little unabsorbed residue as possible. With constipation the opposite should be the aim. In fevers, it is a question, Hutchison thinks, whether we have not gone too far in the reaction from starvation. In all forms the carbohydrates should enter freely into the diet. Obesity is a disorder in which it is easy to overestimate the effects of diet. The proteids are less likely to cause harm than the carbohydrates and fats. Restriction of drinking at meals prevents overeating. Alcoholic liquors are likely to do harm. In diabetics there is a pretty general uniformity as regards diet. In renal disease Hutchison would follow the common opinion that in acute nephritis, especially when blood is present in the urine, an exclusive milk diet gives the best results, but in chronic nephritis affairs are more complicated. We should keep up a vigorous heart. Meats should not be excluded, but foods which contain only the extracts of meats without its albuminous elements should be rigorously avoided. Restriction of fluids in cases of dropsy is not contraindicated, and he would have no hesitation in recommending the dry diet to such patients.

11. **Suppurative Arthritis.**—Barnard would advise that in cases of suppuration of the knee joint with a temperature ranging from 103 to 104 the condition should be treated by anterior and posterior incision, especially if the suppuration results from punctured wounds. If suppuration arises from autoinfection and is subacute, with a temperature of not more than 102, he would be inclined, taught by the cases he here reports, first to make lateral incision on either side of the patella and to wash out the joint thoroughly and drain it. The joint should be treated as though it were an aseptic case, for in autoinfection we have usually to deal with one micro-organism only, and that often a mild one. We should be careful that in casting out one micro-organism we do not admit others worse than the first. Should this partial drainage fail to bring the temperature down in a day or two the posterior pouches should be laid open and thoroughly drained.

16. **Relations Between Fetal and Ordinary Ichthyosis.**—Méneau regards both as links in one chain, different degrees of a single pathologic process. He appends a full bibliography.

17. **Recurring Polymorphous Erythema.**—Gensollen describes 5 and reviews 3 cases already published. The conditions with which it is most liable to be confounded are antipyrin erythema and herpetiform dermatitis. In case of an eruption in round, infiltrated patches, appearing abruptly with identical recurrences and persisting pigmentation, the patient ascribes the eruption to some preceding painful affection instead of to the antipyrin he took to combat it, the true source of the trouble. The pruritus in the affection described in the title is not so intense as in herpetiform dermatitis (Duhring), the attacks are briefer and the lesions are more in the form of a roundish elevation with a central depression. Blebs are accessory and inconstant.

18. **Blastomycetes.**—Gastou exhibited to the Société de Dermatologie specimens of blastomycetes sent by Dr. F. H. Montgomery of Chicago, derived from the lung of a man who had died with generalized blastomycosis. These parasites, Gastou mentions, have been discovered and described only by American writers to date. He queries whether the blastomycetes will share the fate of the coccidia, and suggests that the possibility of a secondary contamination proper to certain lesions or certain countries is not absolutely excluded. There can be no doubt, he adds, that yeasts might easily develop on wounds or ulcerations exposed to the air or defectively dressed. Yeast fungi exist in such numbers everywhere that the only wonder is that the phenomenon is not more frequent. It remains to be demonstrated, he concludes, which among these yeasts are or are not pathogenic or what conditions favor their becoming so.

20. **Eczema a Cutaneous Reaction.**—Brocq maintains that there is no such thing as eczema, but merely eczematous individuals. In a person of this category any one of a number of causes may induce the cutaneous reaction which we call eczema, while in other persons the same causes will never produce it. These causes may be sunshine, wind, light, dust, contact with certain articles of clothing, dyes, etc., intoxications, autointoxication, defective functioning of certain organs, lesions of organs, nervous impressions, worry or other emotions. The physician, therefore, should seek for the underlying cause. A change of environment may cure the most rebellious case. He has known country people cured by a trip to the city, as well as city people cured by going to the country. The diet and mode of life must be regulated in the first place. The patient must be "washed out," that is, put on a strict milk diet, with Vichy water and diuretics, supplemented by a large rectal injection every day or two. If milk can not be taken, he orders a vegetable and water diet. Freedom from worry and plenty of pure air are important; if possible, he sends the patient to the country or, better still, to the mountains. Under this régime the physician is liable to witness the most intractable eruptions disappear with relative rapidity, provided he is content with clean local non-irritating dressings, the parts protected from noxious influences, to enable the skin to repair its lesions with the least possible hindrances. Treatment on these principles will render the secondary exfoliating dermatoses much less frequent and much less severe.

25. **Indications for Surgical Treatment of Gallstones.**—Körte grows more conservative in his indications for operation, with riper experience, but more radical when surgical intervention is once decided on. Rapidly transient icterus with passage of stone is no indication for operation. But when the lithiasis imperils life, even when the attack subsides, there can be no question of permanent healing of the gall bladder in such cases. Severe and complicated cholelithiasis is accompanied by general depression, which may be the first sign of the infection of the gall bladder before icterus attracts attention to this organ. Protracted fever, persisting after an attack, especially if of the remittent type or accompanied by chills, is suspicious of pus formation and indicates intervention, as does also tenderness of the gall-bladder region. Nodules in the liver, with ascites, contraindicate operation, as they are due to carcinoma in an advanced stage, but sometimes inflammatory adhesions in the omentum simulate these nodules. An exploratory laparotomy is justifiable in case of doubt. Chronic empyema of the gall bladder, acute infectious empyema and signs of occlusion of the common bile duct are urgent indications for intervention. The prognosis is good so long as the stone formation is limited to the gall bladder and cystic duct and there are no evidences of intense inflammation. He prefers to take out the gall bladder in most cases, as this does away with the focus of infection. The great majority of stone patients who suffer only occasionally and are well in the intervals, belong in the hands of the physician until the attacks recur so often or are so severe that the patient himself longs for radical treatment or the physician deems that the proper moment for intervention has arrived. The mere existence of stone does not demand intervention. The indications depend on the kind and degree of the resulting inflammation.

27. **Improved Test for Sugar.**—Riegler's test reveals sugar, even in a proportion of merely .05 per cent., and requires only three minutes. The presence of albumin does not interfere with the results. Twenty drops or 1 c.c. of the urine or other solution of sugar is placed in an ordinary rather large test glass, with as much phenyl hydrazin oxalate as can be taken up on the tip of a knife, with 10 c.c. of water. The mixture is then boiled and shaken until all is dissolved. Then 10 c.c. of a 10 per cent. solution of caustic potash is added, the glass stoppered and well shaken, when the fluid turns a handsome purple in less than a minute if it contains sugar. The oxalate can be made by heating 20 gm. of phenyl hydrazin hydrochlorate in 300 c.c. water until dissolved and then adding 10 gm. of ammonium oxalate dissolved in 100 c.c. of water. The crystals are collected on a filter as soon as they are cool and, after rinsing and drying, are ready for use and keep indefinitely.

32. **Success of Pyramidon in Typhoid.**—Valentini proclaims that better results can be accomplished with the continuous administration of pyramidon than with the Brandt baths. The temperature is reduced entirely or very nearly to normal in the course of twenty-four hours and does not rise again. The pulse slows down and the delirium completely subsides. The pyramidon is given in water, .2 gm. in mild and .3 to .4 gm. in the severer cases, the dose repeated every two hours during the entire course of the disease. No inconveniences of any kind were observed, even when the patients took this amount regularly every two hours night and day for four or five weeks. The effect of the pyramidon is so remarkable, he states, that it is not advisable to commence it until the diagnosis of typhoid is positive, as otherwise the symptoms are so masked that the physician is at a loss. The end of the first week is soon enough. The duration of the disease does not seem to be shortened but the patients are able to wait on themselves, and the danger of contagion of others is much reduced, as the patients can use the urinals and bed pans without soiling the linen. Out of 19 typhoid patients treated in this way, 12 were very severe cases, and 2 died, one with pyemia and pneumonia, another from heart failure in the third week. The pulse in the latter case had been continuously bad and the autopsy showed brown atrophy of the heart and enlarged spleen, while the ulcerations were healing.

34. **Reflex Route of Temperature Irritations.**—Kohnstamm is subject to catarrh of the upper air passages, invariably preceded by some exposure to cold, and then assuming the infectious character, contagious for those around him. He has found that careful protection from chilling, especially at night, pyramidon in several doses to a total of .3 gm. and diversion of the mind will prevent and cure the affection. Psychic diversion, he finds, not only diminishes the cutaneous irritation but also the mucous secretion in the most striking manner. He has been studying the reflex routes for these effects in the upper air passages after chilling some part of the body, and gives diagrams to explain his assumption that the temperature and pain fibers run in Gower's tract on the crossed side, and that the "cold" nerve track is in closer relations with the respiration center than the "heat" nerve track. This close connection is the cause of the "chilling reflex." When the microbian factor is added, catarrh is the result. From the respiration center the centers governing the muscles of expiration are irritated to coughing and sneezing, and those governing vasodilation in the vago-trigeminal domain are irritated to congestion. This "chilling reflex" is normally a stimulant for the vegetative processes, and is useful in this respect in "fresh air cures" and light baths.

35. **Action of Intravenous Collargol Injections in Septic Affections.**—Since Credé first suggested, in 1896, the use of soluble silver he has used it in intravenous injection in numerous cases of septic affections, which Schmidt reviews in this article, as also the experiences published by others. A number of cases personally observed are described in detail as typical instances of the benefit derived from the measure. Credé does not think it necessary to call on a catalytic or other action, as he thinks the bactericidal power of silver is sufficient alone to explain the results observed. Beyer has established that a proportion of 1/80,000 in serum nutrient media has an inhibiting effect on bacterial proliferation. All in all, Schmidt concludes, six years of experience have confirmed the fact that we have in collargol an extraordinarily powerful aid for fighting the most diverse infectious conditions, which has won for itself a prominent place in therapeutics, and is free from the limitations of specific curative serums as it is convenient, inexpensive and can be used at any time and in any place in any septic affection.

36. **Toxic Myolysis of the Heart in Diphtheria.**—Eppinger is engaged on a large work descriptive of the pathologic anatomy of fatal diphtheria. In this preliminary report he states that his attention was attracted to the frequency of death from paralysis of the heart after diphtheria, and that he has found that the diphtheria toxin causes a disintegration and dissolving of the heart muscle fibers. He describes the process as "myolysis cordis toxica." He found it pronounced in all the 18 cases he has examined, including one in which serum treatment had not been instituted. He has previously established that in certain disturbances of the hearing subsequent to diphtheria the trouble consists in focal edematous softening of the nerve fibers of the acoustic nerve, and the lesions noted in the heart correspond with this conception of the effects of the toxin.

37. **Antistreptococcus Serum.**—Meyer has been testing Aronson's new serum. It proved very effective in 5 out of 18 cases, but seemed to have little if any influence on the others. It displayed remarkable power in experiments on animals.

Its absolute harmlessness and its efficacy in a certain proportion of clinical cases justify its application on a wide scale.

40. Pseudohermaphroditism and Secondary Sexual Characteristics.—Hengge describes two "sisters," both of whom possessed the bodily and psychic female characteristics except that testicles were present in the large labia. On account of local sensitiveness and general disturbances the testicles were removed from the unmarried "sister." A study of the literature concerning the etiology of the malformation and the development of sex characteristics, as well as a consideration of therapy, lead to these conclusions: 1. Numerous deviations from the usual rule of the dependence of sexual characteristics on the sexual glands are found. 2. The earlier any change occurs in the sexual glands the greater are the changes in the secondary sex characteristics. 3. Congenital disturbances in the sexual glands and secondary characteristics are generally due to mechanical causes. Sometimes trophic or nervous influences may be assumed. 4. In the development of dysmenorrhea and psychic female characteristics in the case of male hermaphrodites, education and example are of great influence. 5. Operative removal of sexual glands is indicated only when they cause much pain and their functionating is impossible.

41. Schatz's Uterine Dilator.—Since all of the usual methods of dilating the uterus, namely, the use of the metrotome, the branched and cylindrical dilators, the tamponade and the swelling tents, have frequently proved imperfect and unsatisfactory, Daniel is surprised that Schatz's metranoikter, first described in 1881, has received so little attention. It consists of two nickel-plated steel semi-cylinders united at one end by a spring of the diameter of an ordinary vaginal speculum. When the half cylinders are held in contact with their flat faces together they form a rod or sound 5.5 cm. long and about 5 mm. in diameter. The dilator is closed and introduced into the uterus by a holder or forceps. The application is easy and requires no anesthetic. Its action is prompt and attended with little pain. It has been used in Prochownick's clinic for the last three years for dilating the uterus previous to curettement and for diagnosis in cases of intrauterine growths. It may also be of value in the induction of labor and some other obstetrical operations.

42. Chorea of Pregnancy.—Hirschl considers the great rarity of this disease, its causes and treatment, and describes a case of severe chorea which terminated in complete recovery after spontaneous premature labor. In regard to treatment *he defends the conclusion of Knapp that in milder cases one should try dietetic and medicinal measures, but that some cases furnish us strict indications for abortion and premature labor.*

43. Obituary of Max Saenger.—Saenger was one of the founders of the "Monatsschrift." Very sympathetic accounts of his life and work are written by his coworkers, Martin and Rosthorn. Then follow the autobiographical and three com- and autobiblio- graphical notes left by this great gynecologist.

44. Hydramnion. *Origin of Liquor Amnii.*—A careful study of the maternal blood and of the liquor amnii in a case of hydramnion in the Leipsic clinic was made for t purpose of studying the origin of the liquor amnii and its increase. A disturbance of the fetal circulation was hologic present in this case, caused by knots in the cord. The ubt of the fetal circulation could not have increased the a. of liquor amnii by increasing the fetal kidney secretion. urinary part of the liquor amnii was diminished, as shown examination. The blood of the mother showed an increa in water and urinary products. Zangemeister concludes tha maternal and fetal blood and liquor amnii are, so far as the crystalloid substances are concerned, a single fluid separated by permeable membranes. *Hence the question of the maternal or fetal origin of the permeable part of the liquor amnii has no significance, as also the presence of urinary products in the liquor amnii has no bearing on its origin from the kidneys.*

45. Structure of Caput Succedaneum.—In numerous sections on new-born children Lönnberg has found that the common description of the caput succedaneum as a subcutaneous transudate is incorrect. He describes and pictures seven serial sections through a large tumor of that kind which show that it is a serohemorrhagic transudation in all layers of the skull covering, including the skin, but that the chief part is between the galea and the periosteum.

46. Uterine Disturbances Due to Infectious Diseases.—A review of the literature shows that exact observations and examinations to determine the effect of acute infectious disease on both the pregnant and the non-pregnant uterus are rare. To fill this lack Stravoskiadis examined, in Weichselbaum's laboratory, 24 cases, including pneumonia, typhoid fever, pyemia, etc. Macroscopic, microscopic and bacteriologic examinations were made. The following conclusions were reached: 1. An acute endometritis which is often hemorrhagic is of frequent occurrence in acute infectious disease. 2. This inflammation is caused by the specific bacteria that cause the disease or a complication. 3. Particularly favorable conditions are present during pregnancy and the puerperium for the increase of the bacteria which reach the uterus through the blood current. 4. Abortion or premature labor is frequently due to endometritis of hematogenous origin.

48. Origin of Uterine Cancer.—Stein reports two rare or unique cases, one of a combination of uterine tuberculosis and cancer and the other of uterine cancer with displacement of mucous membrane within the musculature. He discusses the possible etiologic relation of these conditions to cancer.

50. Eclampsia Statistics.—Schroeder calls attention to the unsatisfactory condition and incompleteness of the eclampsia statistics which give a false picture of the relation between albuminuria and eclampsia. For the purpose of securing more complete data a new scheme of urine examination has been

with coexisting cardiac defect. The diverticula do not cause symptoms so long as there is no inflammation in them. In his own case an old inguinal hernia in a robust man of 71 suddenly became uncontrollable and caused severe pains. All attempts to reduce it were fruitless and a perforation was found near the sigmoid flexure. It was in the middle of a patch of induration the size of a dollar in the intestinal wall and surrounded by evidences of suppurative peritonitis. The hard patch was assumed to be a carcinoma, and the portion of intestine involved was resected and the stumps united by lateral anastomosis. The results at first were good, but the patient succumbed fifteen days later, the heart found much degenerated. The indurated patch that had been resected proved to be merely an infiltration of the subserous adipose tissue; the perforation had occurred in a long narrow diverticulum passing through it. Stierlin thinks that these acquired diverticula would be found more frequently if sought for. Graser found incipient diverticula in 10 out of 38 cases in which the flexure was examined.

65. **Leiter's Apparatus for Local Heat or Cold.**—The apparatus is a sheet of zinc on which a tube is coiled back and forth and soldered, allowing a constant flow of water through it.

66. **Preventive Surgery.**—This address was delivered by Lanz on assuming the chair of surgery at Amsterdam. He asserts that internal medicine has not yet learned to profit by surgery to the fullest possible extent. Disturbances due to mechanical causes require mechanical removal of the cause, active intervention, which the surgeon can now proffer with confidence, as preventive surgery has ripened under the sun of anesthesia and asepsis. He believes in operating every hernia as a prophylactic measure. He noted abnormally large inguinal rings in 140 out of 750 recruits examined, all candidates for hernia later. In regard to appendicitis, he remarks that the first day the prognosis is certain, afterward it is as variable as the disease itself. He operates on the first day whenever possible, especially on children, and the results confirm him in advocating this as a routine measure in all cases of appendicitis, not waiting for further symptoms after diagnosis. He describes a typical case, the child of a physician, taken suddenly with abdominal pains and vomiting. He quieted down under opium and slept tranquilly, but the surgeon was able to palpate a swollen, tender appendix, and it was removed at once and found on the point of gangrene. Lanz believes that certain families have a tendency to appendicitis. He recently operated on three brothers or sisters on one day, all with appendicitis and another sister had passed through a similar experience. Internal medicine must not be jealous of her younger sister, but recognize her as an invaluable ally. The more powerful the ally, the better the results accomplished.

67. **Treatment of Puerperal Infection.**—From his personal observation v. Herff is convinced that the results of causal therapy are not always certain, and treatment is reduced to combating symptoms in most cases. He considers absolute immobilization of the patient very important to favor healing, if necessary using codein or morphin. Involution of the uterus should be promoted in every possible way, and the strength should be kept up by appetizing forced feeding, avoiding alcohol. The heart should be stimulated with small doses of strychnin, which he finds more effective than caffein. The fever requires no treatment unless very prolonged and interfering with sleep. He rejects local treatment. Intrauterine injections might be tried at the onset, but if they fail to benefit they should be suspended early. The curette should not be used at all.

68. **Rectal Feeding.**—Deucher advocates more general use of saline injections, which answer the purpose of transient rectal feeding in cases of inoperable carcinoma of the stomach or esophagus. The patients suffer from thirst rather than hunger, and absorption from the intestines is poor. Saline injections are also useful in cases of heart collapse or diarrhea and also in hyperchlorhydria and atony of the stomach, and occasionally in uncontrollable vomiting. They are useful after abdominal operations as they do not induce reflex phenomena. Actual feeding by the rectum, however, is of especial value in case of recent gastric ulcer or corrosion from caustics. When more substantial alimentation is required, eggs in a saline solution or a solution of cane or grape sugar will be found very useful. The sugar is almost completely absorbed and so rapidly that it does not have time to ferment.

69. **New Treatment of Gallstones—Chologen.**—Glaser explains cholelithiasis as essentially a nervous affection, not primarily an infection. The primary factor is a functional disturbance in the nerves of the liver governing secretion; secondarily, occur excretion of cholestearin and infection of the bile; thirdly, excretion of calcium bilirubinate, and fourthly, the formation and impaction of a stone in the neck of the gall bladder and development of local hyperesthesia. Treatment should combat all these factors. Glaser thinks that he has accomplished this by a combination of mercury with aromatic vegetable substances out of the laxative and bile-stimulating group (podophyllin) and the colic-soothing roots and oils (melissa, camphor and caraway). He uses three combinations, which he calls "chologen Nos. 1, 2 and 3." He has thus treated 73 women and 27 men; 78 per cent. have been completely cured; 16 per cent. improved, and 6 per cent. showed no appreciable benefit. Recurring cholecystitis was the trouble in 33 women and 6 men; 29 women and 4 men were cured, and the others improved, except one woman. Ten women and 3 men suffered from acute occlusion of the common bile duct, all were cured but one woman; from chronic occlusion of the common bile duct, 25 women and 17 men, of whom 19 women and 14 men were cured and the others improved except 2 men. The 78 per cent. whom he calls cured have remained well, with no symptoms of recurrence, are able to work and eat without restrictions. They include a number of very severe cases. There are no contraindications to this treatment, according to his experience. Old and young, cardiac patients and pregnant women took the chologen without inconveniences of any kind. Only in case of catarrh of the large intestine the chologen sometimes induced abdominal pains, but the catarrh was not aggravated and the curative effect of the treatment was not diminished. Even in dubious cases the chologen may prove useful, as he has established its efficacy also in cases of nervous stomach cramps. It will never fail if correctly administered, unless in case of existing empyema of the gall bladder, extensive inflammatory adhesions or malignant neoplasms. He considers the appearance of icterus a favorable sign, as it indicates that the stone has passed into the common bile duct, and this class of cases responds the best to chologen treatment. He relates typical examples, among them the case of a man of 49 who had suffered for ten years from gallstones. The attacks were frequent and extremely painful, with pruritus and icterus, constipation or diarrhea, the urine red and dark colored, the patient extremely feeble. Two tender points were found, one over the gall bladder and the other typical of chronic occlusion of the common bile duct, about 3 finger-breadths above and to the right of the umbilicus. Four weeks after the chologen treatment was instituted the patient returned strong and apparently well and has been healthy since then (July, 1901). The preparation of the chologen tablets has been entrusted to the laboratory of H. Rosenberg, Achenbachstrasse 2, Berlin W. They can be obtained only on a physician's prescription. Besides this mercurial chologen treatment Glaser insists on relief from nervous strain, out-of-door exercise, the diet regulated but abundant, and meat and vegetables allowed. Warm saline baths are valuable adjuvants. Some of the disturbances may be caused by adhesions, and these can be remedied by wearing a supporting bandage or reclining on a certain side. When an attack threatens he applies a flannel cloth moistened with equal parts poppy-seed oil and chloroform. The total amount of mercury taken in the three to four months' course of chologen treatment is only .5 to 1 gm. In a second communication in No. 6 he states that his second series of 100 cases has proved equally successful.

continued as a three-hourly medication. On this day she was taken to the operating room and her uterus emptied by curettage of a large amount of decomposing placental tissue. This was done without an anesthetic. The interior of the bladder was at the same time cursorily examined with a cystoscope and found to be both normal in appearance and empty. During this day the bowels moved seven times, and the stool contained blood. The patient vomited a great deal and did not retain much nourishment. The diuretin seemed to be the cause of the gastric irritation, and was discontinued after 12 hours' trial. The total amount of urine obtained by the many catheterizations did not exceed thirty drops. The hot-air baths were continued, but no more salt solution was injected into the veins. It was considered that in the absence of results from the injection of 8 quarts in 24 hours nothing could be expected from further repetitions of the dose. The patient slept fairly well.

FIFTH DAY OF SUPPRESSION.

March 3.—Temperature remained below 99.6 F., pulse 74 to 80, respiration 20. Calomel was continued in one-fourth grain doses every three hours. The bowels moved 7 times. Steam baths, for 25 minutes, were continued. Patient continues to vomit. A sum total of ten drops of urine was obtained by catheterization during the 24 hours. The stool of the patient was examined for urea and found to contain 0.6 per cent.

SIXTH DAY OF SUPPRESSION.

March 4.—Temperature 98.2 to 98.8 F., pulse 70 to 84, respiration 20. Patient slept a great deal. Bowels did not move so freely. An attempt was made to place patient in cabinet bath, but she was too weak to sit up and the steam baths were therefore continued. The patient felt well while in bed. She complained of no headache, no ocular symptoms; in fact, no pains in any region. The calomel was continued. Ten drops of urine are recorded for this period of 24 hours. The character of this urine remained the same. The stool of the patient was again examined for urea and found to contain 0.7 per cent. The uterus was irrigated because of a continuance of a discharge from the external os. On this date patient was taken to operating room, and a second examination of bladder made. The bladder was normal in color, not inflamed and empty. No water could be seen to issue from the ureters and certainly none collected in the bladder during the half hour that the examination was continued with the bladder distended by air. There was no evidence of a calculus in the orifice of either ureter and no bulging at this site. On the contrary, the right ureter was widely open. During each day of the disease the kidneys were both thoroughly and satisfactorily palpated with a view to detecting a developing hydronephrosis from simultaneous obstruction of the ureters by calculi. The kidneys could be felt to be somewhat enlarged from the start, but there seemed to be no progressive increase in their size.

SEVENTH DAY OF SUPPRESSION.

March 5.—Temperature remained 98.6 F., pulse 72 to 90, respiration 20. General condition shows marked failure in strength. The patient slept most of the time and was aroused with difficulty. Citrate of magnesia was given; strontium bromid was given in 10-grain doses every four hours as a diuretic. Calomel was continued. Bowels moved eleven times. Urine was obtained four times by catheter; on two occasions one dram was obtained, on another one-half dram, on another four drops. This urine was examined carefully. The reaction was acid, color amber and cloudy, albumin was present in considerable amount, sugar was absent. The urea percentage was 1.4. On microscopic examination no casts were found, but three varieties of cells were present—white blood cells, bladder epithelial cells and round kidney cells. The white blood and the bladder epithelial cells presented the usual appearance, but the kidney cells presented a most striking example of fatty degeneration. This condition of the kidney cells had been noted in the urine of the preceding days, but to so slight a degree that it was not given much thought. The four specimens obtained at different times on this seventh day of the suppression demonstrated a very rapidly-increasing number of these fatty cells until the evening specimens presented a most striking picture.

The rapidly increasing numbers of degenerated kidney cells were considered to indicate that the kidney parenchyma was undergoing rapid degenerative changes by reason of the prolonged stasis of blood in its vessels. It was taken as an index of the pathologic changes taking place in the kidney and as a finger-board pointing out the correct line of treatment.

The condition of this patient had been explained from the start, in the writer's mind, on a basis of vasomotor disturbance whereby a stasis of blood, probably under great tension, had occurred in both kidneys. Blood was not flowing through the glomeruli, therefore the secretion of urine was in abeyance. The medication employed was directed to a re-establishment of this circulation and to an elimination of as much urea as possible by way of the skin, bowels and lungs. A continuance of this medication and general line of treatment was believed to be justifiable so long as the condition of the patient remained fairly good. Nevertheless, the operating-room force was held in readiness during this entire time for such operative treatment as might be demanded.

The definite evidence of rapid degenerative changes in the parenchyma of the kidney seemed to the writer to present a positive indication for such operative intervention and the patient was accordingly prepared for this treatment.

On March 6, and at the completion of her eighth day of suppression, the patient was taken to the operating room. Chloroform was used as the anesthetic. The right kidney was exposed by an oblique incision in the loin through all structures (the possibility of extension of the incision for the exploration of the ureters made a muscle-splitting operation undesirable). This kidney was certainly one-half larger, if not double the size of a normal kidney. Its external surface presented a mottled, purplish-blue appearance which at once suggested the appearance of the face of a baby whose head had just been born with the cord compressed. The kidney was lifted from its bed and the body of the kidney, the pelvis and the ureter thoroughly palpated. Nothing abnormal could be found and the pelvis certainly was not dilated. A hollow needle was thrust into the pelvis through the cortex for the double purpose of probing for stone and drawing off urine from a dilated pelvis. This investigation gave negative results.

The opinion already expressed regarding blood stasis seemed confirmed and the capsule of the kidney was split from end to end and totally removed. When an incision was made in the capsule its edges retracted and the cortex bulged through the incision as if under great tension, this in a manner entirely analogous to that seen in brain operations when the dura is opened. Very free hemorrhage followed the separation of the capsule from the kidney, but this membrane was nowhere firmly attached to the cortex by fibrous wedges projected inward. The capsule was of about normal thickness and was stripped off easily. The kidney parenchyma was of a yellowish-gray appearance after the blood-letting of decapsulation and was so brittle that the slightest touch of an instrument seemed to lacerate it. At one time my assistant changed the position of a very blunt abdominal retractor, and in so doing struck the convexity of the kidney. A lacerated wound three-fourths of an inch long and one-half inch deep resulted. The naked eye appearance of the cortex was that of marked fatty degeneration. The capsule of the kidney was entirely excised, the kidney dropped back into its bed, gauze drainage was inserted and the external wound closed. A provisional stitch was inserted for the purpose of completing the primary closure of the wound after the removal of the drainage 24 hours later.

Exactly the same procedure was immediately applied to the left kidney. This organ presented precisely the same anatomic conditions; the pelvis was likewise found to be free and the capsule was removed. The time consumed in the double operation was 45 minutes. The patient stood the operation perfectly well, her pulse did not exceed 100, and she was put to bed in a most satisfactory condition. At the time of her return to bed the pulse was 70 and the respirations 20 per minute. There was no vomiting from the anesthetic.

One hour after operation the patient expressed a desire to urinate and two ounces of intensely bloody urine were obtained by catheter. This urine was neutral in reaction, albumin was abundant in a filtered and centrifuged specimen and the urea percentage was 1.4. Microscopically red blood cells were present in large numbers; the same round cells presenting in advanced stage of fatty degeneration were found in abundance, but no casts.

The temperature remained normal throughout the remainder of the day, the pulse varied from 72 to 80, the respirations from 24 to 28.

At 6 p. m. (six hours after operation) 2¼ ounces of urine possessing the same naked eye, chemical and microscopic characteristics were voided by the patient.

At 9 p. m. 1¾ ounces of urine of similar nature were voided.

The patient was given water per mouth in six hours after operation.

At 1:30 a. m. 2 ounces and at 5:30 a. m. 4¼ ounces were passed. Three ounces at 8:30 a. m., and 4 ounces at 11:40 a. m., gave a sum total of 21 ounces of urine passed in the first twenty-four hours after operation.

The urine continued to be intensely bloody, the reaction became acid at 1:30 a. m., the specific gravity was 1,009, and the urea percentage had diminished to 1 in the morning urine. The fatty cells persisted to the end of the twenty-four hours. An 8-ounce bottle containing the first urine passed showed a red deposit ¼ inch thick after settling for a few hours. The patient was rather drowsy during the day, had some abdominal pain, and vomited once.

The second twenty-four hours after operation, the temperature, respiration and pulse remained normal. The urine was passed in from 3 to 10-ounce quantities and aggregated 48 ounces. The blood rapidly disappeared and the urine became amber color by the end of this period. The reaction continued to be acid. The specific gravity did not vary from 1,008. The urea percentage varied from .85 to 1.5. Albumin was present. Red blood cells were always present microscopically. The fatty cells had disappeared by the end of the period. No casts were found in any specimen.

The patient rested well, took liquid food with much indifference, and vomited bile once or twice. She was delirious for two hours during the night, but slept well with this exception. The gauze drainage was removed and the provisional sutures tied.

The third twenty-four hours after operation, temperature, respiration and pulse remained normal. The amount of urine aggregated 89 ounces. The character was about the same as that during the second 24 hours except that it became bloody again for about six hours, then returned to amber. The patient rested well. The diet consisted of toast, egg, cocoa, oyster broth, ice cream, and orange albumin water. There was great prostration, but patient was cheerful. The bowels moved well.

The fourth twenty-four hours, temperature, respiration and pulse normal. Total amount of urine 56 ounces. Urine clear; very few red cells; no casts; trace of albumin; specific gravity 1,009; reaction acid; no sugar.

The fifth twenty-four hours, temperature, respiration and pulse normal. Total amount of urine 77 ounces. General condition good. Quality of urine the same as during the fourth day. Appetite vacillating. Some delirium at night, yet patient slept well. Patient received eggnog and strychnin sulphate grs. 1/60 as continuous tonic stimulation.

The sixth twenty-four hours, temperature and respiration normal. Pulse became elevated to 100. Total amount of urine 64 ounces. Urine amber color and cloudy; reaction acid; specific gravity 1,009; trace of albumin; no sugar. Microscopically amorphous urates, a very few red blood cells and no casts were found. Urea percentage 1.4.

The seventh twenty-four hours, temperature 98.4 to 99.2, pulse 90 to 120 and bounding, respiration 20 to 26. Total amount of urine passed 47 ounces. Quality of urine same as on sixth day. Patient felt very weak and looked very pale, but said that she had no pain and felt very well. Appetite failed somewhat.

The eighth twenty-four hours, temperature, respiration and pulse normal. Total urine 52 ounces. Quality same as on sixth day.
